# INDEX TO VOLUME CXXIV.

**Abbot, A. C.** Corrosive sublimate as a disinfectant, 591.  
**Abbot, S. L.** Case of extraordinary accumulation of feces, 109; esophageal obstruction due to a piece of lettuce, 114.  
**Abbott, S. W.** Recent progress in public hygiene, 287, 309.  
**Abdominal surgery.** The technique of successful abdominal and pelvic surgery, Wathen, W. H., 536.  
**Achorn, J. W.** Tuberculosis in children: some phenomena attending initial injections with Koch's fluid, 61.  
**Adinam.** Todd, H. J., McC., 519.  
**Alapay.** Sterilization of rubber catheters, 126.  
**Albuminuria.** Etiology and prognosis, Jackson, H., 477, 482; physiological albuminuria, 539.  
**Alexeevsky.** The red-rose petals as a remedy for diarrhoea, 491.  
**Allen, G. W.** The treatment of acute urethritis, 525, 533; cases of renal colic, 527.  
**Alopecia universalis.** Cathell, D. W., 556.  
**Amenorrhoea.** Some forms of amenorrhoea and their treatment, Davenport, F. H., 380; amenorrhoea: clinical report of four cases successfully treated by galvanism, Strong, C. P., 382, 388.  
**Anatomy.** Are anatomy and physiology liberal studies? 111; methods of teaching anatomy at the Harvard Medical School, especially corrosion preparations, Dwight, T., 475; recent progress in anatomy, Dwight, T., 554.  
**Andeer.** Reservoir in septic poisoning, 197.  
**Andrews, E.** Cadaver studies on the removal of the semilunar ganglion through the floor of the cranium, 537.  
**Aneurism.** Suspected aneurism of the aorta, Knight, F. L., 65, 89; the cure of aneurism, Macceven, W., 222.  
**Aniline dyes.** The subcutaneous use of aniline dyes, Mosetig and Stilling, 345.  
**Animals.** Poison-proof animals, 101; the relation of diseases of animals to those of man, 257; tuberculosis of cattle in New York, 333.  
**Apostoli.** Notes of five cases from Dr. Apostoli's clinic in Paris, Van Pelt, G. W., 253.  
**Appendicitis.** A case of relapsing appendicitis in which the appendix was removed in an interval between the attacks, with recovery, Cabot, A. T., 57, 63; discussion by the Medical Society of the State of New York, 213; in recurring appendicitis is excision of the appendix during a remission a justifiable operation and if so, in what class of cases, and how, should it be done? Porter, C. H., 68, 325; specimen of an appendix, Elliot, J. W., 363; appendicitis: a year's experience in private practice, Elliot, J. W., 499; appendicitis and pericecal inflammations, Morton, T. G., 510; recurrent appendicitis with adhesive bands about the head of the colon, operation followed by cure, Marcy, H. O., 524.  
**Army.** The relations of contract surgeons to the general profession, 488.  
**Arrow poison of the pigmies.** Parke, 500.  
**Arsenic.** A new source of arsenic poisoning, Swift, W. N., 185; legislation concerning arsenic, 217; general peripheral neuritis, Folsom, C. P., 291; arsenic in the Massachusetts legislature, 396; legislation on arsenic in Massachusetts, 392; the character of the evidence as to the injuriousness of arsenic as a domestic poison, Putnam, J. J., 623.  
**Aschby, T. A.** Ruptured tubal pregnancy, 586.  
**Asparagus.** The effect of asparagus on the urine, Nencki, 495.  
**Astringents.** The internal use of the simple astringents, Walker, M. A., 569.  
**Atropia.** The use of atropia in treatment of localized muscular spasm, Leszynski, W. M., 315.  
**Ayer, J. B.** Variella in an adult, 607.  
**Bagninsky.** The treatment of tetanus by injection, 271.  
**Baker, W. H.** Fibro-sarcoma of both ovaries, enucleation, recovery, 325.  
**Barbot, L. J.** Tidal drains at Charleston, S. C., 15.  
**Barnes, E. J.** Sewage: application to land the best method of treatment, 229, 236, 256.  
**Bass, G.** Pathology of grief, 418.  
**Bosch, H. H. A.** Koch's remedy in Boston, 42.  
**Bell, A. N.** Some of the sanitary features of Charleston, S. C., especially its artesian wells and its tidal drains, 15.  
**Benezar and Jones.** Thoracic palpation, 126.  
**Beri-beri in Japan.** Takaki 29.  
**Berlioz.** Microclime, 591.  
**Bibliography.** Agnew, D. H., the principles and practice of surgery, being a treatise on surgical diseases and injuries, 538; Agnew, W. P., treatment of hemorrhoids and other non-malignant rectal

diseases, 538; American Orthopedic Association, transactions, 11, 511; Bateman, F., on aphasia, or loss of speech, and the localization of the faculty of articulate language, 365; Baudouin, M., hystéropexie abdominale antérieure et opérations suspubiques dans les retrodévations de l'utérus, 95; Bennett, G., the modern malady, or sufferers from "nerves," 240; Bennett, W. H., clinical lectures on varicose veins of the lower extremities, 511; Binet, A., on double consciousness, experimental psychological studies, 120; Bissell, M. T., household hygiene, 16; Boston, annual report of the Board of Health, 306; Boston City Hospital, report for 1890, 439; Browne, L., the throat and nose, and their diseases, 16; Campbell, H., flushing and morbid blushing, their pathology and treatment, 339; Drayton, H. S., human magnetism, 464; Edinger, L., twelve lectures on the structure of the central nervous system, 586; Edis, A. W., sterility in women, including its causation and treatment, 120; England, eighteenth annual report of the Local Government Board, 1888, 1889, 17; England, nineteenth annual report of the Local Government Board, 491; Gautier, G., le courant continu en gynécologie, 538; Graham, D., a treatise on massage, theoretical and practical, its history, mode of application and effects, indications and contraindications, and results in over fifteen hundred cases, 514; Grandin, E. H., and Gunning, J. H., practical treatise on electricity in gynecology, 538; Hammond, W. A., a treatise on the diseases of the nervous system, 562; Haro, H. A., epilepsy, its pathology and treatment, 339; Harvard College, annual reports of the president and treasurer, 193; Illinois State Board of Health and medical education, 242; Keen, W. W., operation blank, 514; King, A. F., a manual of obstetrics, 69; Kirminson, leçons cliniques sur les maladies de l'appareil locomoteur, 457; Ladard, étude sur la rage et la méthode, l'astuce, 339; Martin, E., Saunders' question compends, No. 2, essentials of surgery, together with a full description of the handkerchief and roller bandages, 511; Massachusetts General Hospital and McLean Asylum for the Insane, report for 1890, 294; Massachusetts vital statistics for the year 1889, 195; Massachusetts report on water supplies, 516; Mitchell, C. P., the philosophy of tumor disease, a research for principles of its treatment, 16; Morris, H., a compend of gynecology, 514; Murrell, W., massotherapy, or massage as a mode of treatment, 514; navy, report of the chief of the Bureau of Medicine and Surgery to the secretary of the navy, 18; New York, annual report of the State Board of Charities, 219; New York City, annual report of the Board of Health, 329; New York State Board of Health, report, 172; Pasteur Institute, New York, first annual report, 321; Post, S. E., massage, a primer for nurses, 269; Reese, J. J., a text-book of medical jurisprudence and toxicology, 538; Robe, G. H., text-book of hygiene, 209; Smith, J. L., a treatise on the diseases of infancy and childhood, 563; Snow, H. P., the proclivity of women to cancerous diseases, 537; Starr, M. A., familiar forms of nervous disease, 349; Stevenson, W. E., the use of electrolysis in surgery, 437; United States marine-hospital service, annual report, 241.  
**Richschowsky.** Trophic changes in the nails in multiple neuritis, 475.  
**Rile.** Biliary lithiasis, 468.  
**Billings, J. S.** American inventions and discoveries in medicine, surgery and practical sanitation, 349; ideals of medical education, 619.  
**Binet.** Powers of perception of children, 494.  
**Biography.** Alcock, J. W., 616; Baillarger, J. G. F., 152; Balfour, T. G., 152; Bancroft, J. P., 474; Barker, E., 569, 593; Bartlett, T. H., 516; Batgate, J., 372; Becquerel, A. E., 522; Bellamy, E., 104; Bigelow, H., 194, 271, 294; Biologic, K., 379; Holling, W. H., 401; Borelli, G., 152; Botwell, G. W., 476; Bruce, G. D., 550; Burwell, G. N., 522; Butcher, R. H., 373; Chase, S. L., 224; Chessmore, H., 128; Coccius, E. A., 21; Coles, A., 438; Cowdry, S. G., 215; Corley, A. H., 21; Corbin, E. L., 152; Cummings, J. B., 376; Cutler, G. R., 197; Davis, J., 52; Dexter, K., 396; Doe, O. W., 32, 189; Dow, W. G., 498; Dubois, C., 76; Duval, M., 224; Eldridge, J. H., 224; Ehot, G., 570; Edinger, W. von, 52; Fennel, A. G., 275; Fox, L. S., 646; Garish, J. P., 372; Gary, T. P., 618; Gay, H. S., 372; Geddes, H. W., 275; Gibson, R. P., 241; Gill, H. S., 441; Goldberger, E., 108; Gordon, A., 324; Gordon, D. H., 396; Gori, M. W., C., 76; Grimshaw, A. H., 522; Graves, L. J., 224; Gulliver, G., 128; Gundry, R., 474; Guiterroz, N., 200; Halsey, G. L., 223; Hartnack, E., 218; Harvey, J., 24; Harwood, C. G., 441; Hewitt, P. G., 646; Hild, E., 32, 189, 248; Hosmer, A., 323; Hosmer, H., 323, 345; Jendrassik, E., 372; Jensen, J., 622; Johnson, H. A., 284; Jones, S. P., 324; King, G. A., 522; King, H. C., 224; Knight, H., 483; Kretschmar, P. H., 474; Lane, J. R., 646; Leidy, P., 474; Livermore, A. C., 309; Logan, J.

Hydrochloric Acid. Tests for free hydrochloric acid, 170.

- serious injuries to recovery in two thousand cases of insanity, Cranger, W. D., 115; annual report of the New York State Commission in Lunacy, 117; changes in the blood and urine of the insane, Smith, J., 345; stuporose insanity following hypnotism, Nolan, 345; Ideoxy and the obstetric forceps, Winkler and Bollaun, 471; report on mental diseases, Steinhart, H. R., 327; case, the gynecologist aid the alienist in institutions for the insane, Stone, J. S., 636
- Mittendorf, W. F.** One thousand cases of ocular headache and the different states of refraction connected therewith, 213.
- Mixer, S. J.** Further observations on permanent tubage of the oesophagus, of two cases, 119; the division of the division of the fifth pair of nerves at the foramen ovale for neuralgia, 115; a fatal case of perineal section for rupture of the urethra, 115.
- Monks, G. H.** Operations for correcting the deformity due to prominent ears, 84, 94; the remains of a broken lead-pencil surrounded by inflammation for the fissure of Stone, 115; the tip of the pencil removed from the bladder by perineal section, 182.
- Montzambert, F.** The vaccinal protection of passengers from Cuba, 15.
- More, J. T.** A case of penetrating wound of the abdomen and thorax, recovery, 259.
- Morison.** Lichen rubra treated by Koch's method, 192.
- Morrill, F. G.** A case of cardiac dropsy, 287.
- Morton, T. G.** Appendicitis and pericecal inflammations, 511.
- Moss, J. W.** Methyl violet in the treatment of malignant growths, 246.
- Mosetig and Stilling.** The substantive use of aniline dyes, 345.
- Mueller.** Strychnine in snake-bite, 456.
- Munford, J. G.** Angioneurotic oedema, 235.
- Mushrooms.** The study of mushrooms, Forster, E. J., 59.
- Naegeli.** A simple means of jugulating cephalalgia and facial neuralgia, 125.
- Nail-brushes.** Sterilization of nail-brushes, Spielhagen, 471.
- Nails.** Tropic changes in the nails in multiple neuritis, Bielschowsky, 175.
- Naphthol.** Alpha and beta naphthol, 175.
- Navy.** Report of the chief of the Bureau of Medicine and Surgery to the secretary of the navy, 1.
- Nelson, S. N.** Conservative surgery applied to a case of gun-shot wounds where four large pistol balls entered the body and only one ball was removed, 526, 532.
- Neukel, L.** Injections of pyoktatin in cystitis, 126; the effect of pyoktatin on the urine, 126.
- Nervous System.** Recent progress in diseases of the nervous system, Knapp, P. C., 8, 31; provision for the care of adult pauper epileptics in Massachusetts, Bullard, W. N., 25, 36; cerebral tumors, clinical cases, Steinhart, J., 79, 90; progressive paralysis, Pick, 102; a case of spina bidda, Athrop, W. H., 114; two cases of excision of the third division of the fifth pair of nerves at the foramen ovale for neuralgia, Mixer, S. J., 115; a simple means of jugulating cephalalgia and facial neuralgia, Naegeli, 125; treatment of epilepsy by the combination of strychnine, ammonia and bromide of ammonia, Potis, C., 126; a case of successful trephining for subdural hemorrhage produced by contre-coup, Homans, J., and Walton, G. L., 153, 163; early diagnosis of some serious diseases of the nervous system, its importance and feasibility, Seguin, E. C., 129, 177, 201; tumor of the centrum ovale, Knapp, P. C., 157; two cases of traumatic neuralgia, Hun, H., 188; one thousand cases of ocular headache, and the different states of refraction connected therewith, Mittendorf, W. F., 213; some points on the pathogenesis of aural vertigo, Pomeroy, O. D., 214; the pathology of hysterical joint disease, Prince, M., 269; the treatment of tetanus by injection, Baginsky, 274; antipyrin and exalgin in chorea, Legros, C., 274; general peripheral neuritis, Polson, C. F., 291; comparison of the ocular troubles in locomotor ataxia, multiple sclerosis and hysteria, 293; the degenerative disease of the spinal cord, with a description of a new type, Dana, C. L., 315; cerebral syphilis, Thomas, H., 338; the virile reflex, 335; an hereditary type of motor tics, Knapp, P. C., 409; a case of spastic paraplegia, compensatory gait, Birdsall, 419; clinical and pathological observations on injuries of the cervical spinal cord, Hertel, C. A., 419; cerebellar tumor, operation, hemorrhage from defect of occipital bone, digital, general remarks, Bullard, W. N., and Bradford, E. H., 424, 435; simulated primary dementia, a medico-legal case, 430; counter-irritation, Burr, C. R., 432; the pathology of Landry's paralysis, Hun, H., 485; contribution to the pathology of infantile cerebral palsies, Sachs, E., 496; cadaver studies on the removal of the semilunar ganglion through the floor of the cranium, Andrews, E., 537; pistol-shot wounds of the skull, Bradford, E. H., 576, 580; tumor of the brain, Putnam, 607; cases of pain (on wax) in the sole of the foot, radiating out to certain toes, Putnam, J. J., 607.
- Newell, O. K.** Styrene, 435.
- New Jersey.** Repeal of charter of Medical and Surgical College of New Jersey, Watson, 435.
- Newman, R.** Demonstration of modus operandi in the treatment of urethral structures by electrolysis, 12.
- New York.** Death-rate of New York, 429.
- Nichols, A. H.** Stimulated primary dementia, a medico-legal case, 430.
- Night Sweats.** Camphoric acid and tellurate of soda in night sweats, two new auridic medicaments, 194; treatment of night sweats of phthisis, Huchard, 471.
- Nolan.** Stuporose insanity following hypnotism, 345.
- Nomenclature.** Uniform nomenclature in orthopedic surgery, Townsend, W. R., 413.
- Northrup, W. P.** Tuberculosis in children, primary infection in the bronchial lymph nodes, 143.
- Nothing new under the sun.** 102.
- Obstetrics.** Recent progress in obstetrics, Green, C. M., 87.
- Oedema.** Angioneurotic oedema, Munford, J. G., 235; case of acute local oedema complicated with purpura and salivation, Holmes, W. H., 481.
- Oesophagus.** Further observations on permanent tubage of the oesophagus, Mixer, S. J., 5, 11.
- Orexin.** Effects of orexin on assimilation, Kotlar, E. T., 222.
- Orthopathy.** The etiology of lateral curvature of the spine, Lovett, E. W., 6; notes of the Complicating Pot's disease, Wiegell, L. A., 168; the relation of orthopaedic surgery to general surgery,
- Shallier, N. M., 363; a cheap lip-split, Lovett, E. W., 259; an apparatus for the correction of talipes equino varus, Lane, J., 369.
- Osmond, H.** The outcome of personal experience in the application of hypnotism and hypnotic suggestion, 277, 289, 303.
- Ossler.** Multiple cysticercoid or cysto-tuberculosis, 192.
- Ostermayer.** Sulphate of dobioisine as a sedative and hypnotic 303.
- Otis, W. J.** Method of high rectal inspection, 361.
- Ott.** Periodicity of physiological functions in women, 126.
- Ovaritis.** The pathology and treatment of chronic ovaritis, Skene, A., 361.
- Page, R. C. M.** Phthisis, its classification, early diagnosis and relations to chronic pneumonia, 142.
- Palmer, L. M.** Case of a man struck by lightning, recovery, 231.
- Palpation.** An aid to palpation, Chipmowick, 519.
- Parkes, C. T.** Cyst of the pancreas treated by laparotomy and drainage, recovery, Richardson, M. H., 111.
- Parisi.** Cocca-put oil as an antiseptic, 150.
- Par-c-e.** Arrow poison of the pigmies, 590.
- Parker, C. T.** Cyst of the ovary, with a pregnant uterus with fibroid tumor, 539; laparotomy for extra-uterine pregnancy two months after death of fetus at term, 540.
- Parotiditis** from pneumococci, 149.
- Petrescu.** Digitalis in pneumonia, 520.
- Pfeiffer.** The report of a case of phlegmasia dolens, Thompson, G. E., 604, 605.
- Phthisis.** its classification, early diagnosis and relations to chronic pneumonia, Page, R. C. M., 142; combination of operative treatment with medical treatment in phthisis, Southburg, 150; the treatment of the pyrexia of phthisis, Williams, 394; the treatment of phthisis by medicated air under pressure, See, G., 619; iodide of potassium for the diagnosis of phthisis, Sticker, 568.
- Physiology.** Vital phenomena after decapitation, Laborde, 590.
- Pig.** The anatomy and physiology of the pig, 590.
- Poisons.** A new source of arsenic poisoning, Swift, W. N., 185; a stomach, oesophagus and duodenum showing the caustic effects of a fatal dose of carbolic acid, Draper, F. W., 11; arrow poison of the pigmies, F. C., 590.
- Polkier.** Foreign bodies in the oesophagus, 166.
- Polk, W. M.** Conservatism in dealing with the appendages, 526.
- Pomeroy, O. D.** Some points on the pathogenesis of aural vertigo, 213.
- Porter, C. B.** The removal of the appendix during a remission in cases of recurrent attacks of appendicitis, 68; in recurring appendicitis is excision of the appendix during a remission a justifiable operation and if so, in what class of cases, and how, should it be done, 88, 325.
- Pot, A. H.** Prostatotomy in a patient of forty-two, 405.

## Lecture.

### ON THE TREATMENT OF TUBERCULOSIS BY KOCH'S METHOD.<sup>1</sup>

AN ABSTRACT OF SEVERAL CONFÉRENCES RECENTLY DELIVERED IN COCHIN HOSPITAL.

BY PROFESSOR DUJARDIN-BEAUMETZ, PARIS, FRANCE.

[Dr. Ley, of Paris, having, about December 1st, returned from Berlin, where he had been for some time watching the effects, in the hospitals, of Koch's treatment, brought with him a quantity of the "material" with which experimentation had been begun in Cochin Hospital, under the supervision of Dr. Dujardin-Beaumetz.]

It was at the Berlin Congress in August, 1890, that Koch first announced that he had found a new method to combat tuberculosis in animals and perhaps in man. Then, in November, he made another communication, and showed that by injecting a substance whose composition is still unknown, and which is denominated *Koch's mittel*, certain general symptoms could be produced followed by reaction in the parts in which the bacilli are seated; and Koch had the hardihood to assert that we are henceforth in possession of a curative method, not only for external and surgical tuberculosis, but also for pulmonary phthisis in its first stages.

With commendable prudence and reservation, Koch added that he did not know how long individuals who had been under treatment would remain refractory to tuberculosis, and that, moreover, in advanced pulmonary tuberculosis, the method would probably be inefficacious, and on this account it would be necessary always to treat phthisical patients by the usual methods.

This communication produced a tremendous sensation all over the world, and since then patients and physicians have, from all countries, been flocking to Berlin.

Lastly, a declaration to the Parliament of Berlin by the Minister of Public Instruction gives us to understand that the German Government, with Koch's consent, in view of the dangers which might result from a defective preparation of the fluid, has insisted that the process of fabrication shall be kept secret a long time.

To-day the production of this material seems to be sufficiently abundant to warrant the carrying out of clinical experimentation in all parts of Europe, and we are now in position to gather together a large number of observations so as to enable us to acquire some precise data as to the value of these injections.

It is probable that Koch's *mittel* consists essentially of a toxine or a toxalbumin, the result of a process of special culture of a bacillus.

In this connection, I ought to recall to your mind two interesting facts. Two years ago, Roussy, assistant to Professor Hayem, made a communication to the Academy, which showed that certain diastases, and, in particular, that which inverts sugar, cause, when injected into the veins of animals, a very pronounced febrile accession. Although we are ignorant of the true nature of the diastases, authorities are disposed to class them in the same category with the toxines secreted by micro-organisms.

I must refer you also to the interesting and instructive communication made to the Berlin Congress by Professor Bouchard; you will there see that the patho-

genic microbes secrete toxines which may be useful as preservative vaccines against the disease of which they are the factors.

Some have thought that, in order to separate this toxine, Koch had been making use of Brieger's process. You know that Brieger employs the salts of gold to effect this separation; and, as in a previous communication, Koch has shown that the cyanide of gold was the most powerful microbicide of tuberculosis, it was at first supposed that his fluid contained both the toxalbumin of which I have spoken, and cyanide of gold. New analyses seem to indicate that the salts of gold do not enter into its composition, but the whole matter is still hypothetical and it seems probable that for a long time, perhaps for years, we shall remain ignorant both of the composition of this *mittel* and the processes for its obtention.

I come now to the clinical and experimental facts; here the accord seems to be unanimous, as far as the effects produced by injections of the material are concerned.

When, in a patient affected with tuberculosis, and, for the first time, a minimum dose of the lymph is injected, say, one to two milligrammes, you will observe in the course of from five to twenty-four hours quite marked inflammatory phenomena in all the points where tubercle bacilli abound. In the case of cutaneous tuberculosis, you can closely follow this inflammatory process, and you can readily understand what must take place in the internal organs, lungs, kidneys, and in the joints. It is, then, a reagent of exceeding power, and this fact shows the necessity of great judgment and caution when you propose to provoke such an inflammatory reaction in sensitive organs such as the meninges, peritoneum, or larynx.

As for the question of therapeutics, with which we are more immediately concerned, we have thus far conjectures rather than exact data; and it must be admitted that these conjectures are rather unfavorable than favorable, for we have no positive instance of cure, and relapses seem to have been frequent. But, in order to decide concerning the value of a therapeutic method directed to tuberculosis, it is by months and years of experiment that we must reckon.

But, if we leave to one side all questions as to the therapeutical value of the discovery, and consider it only from the point of view of the symptoms which it determines, I cannot but regard this discovery as of considerable importance in its consequences. Its results confirm absolutely what Pasteur announced ten years ago at the International Congress in London, that is, that, in honor of Jenner, he had aggrandized this term *vaccination*, and was applying it to the treatment of infectious diseases; and the celebrated experiment of Pouilly-le-Fort, when the protective virtues of attenuated anthracoid-vaccinations were tested, raised hopes of the possible future triumph of similar methods in the stamping out of other infectious diseases. It is in this direction that Koch has been working, and it is in perfecting these methods that other experimenters are destined to win success.

What shall we say of this selective action of a medicament on certain pathological elements of the economy — a selective action which leaves untouched the other healthy elements — is it peculiar to Koch's fluid? By no means, gentlemen. And we have in the action of iodide of potassium in syphilis an instance of a precisely similar kind, both from a diagnostic and thera-

<sup>1</sup> From Advance Sheets.

peptic point of view. What there is especially interesting in the discovery of Koch, is that he has founded his treatment essentially on the use of certain tox-albumins secreted by the micro-organisms; that he practises veritable vaccinations, as we understand the term, according to Pasteurian theories. I pass now to the history of the few patients who have been the subjects of our injections.

CASE I. A boy, eighteen years of age, without hereditary antecedents. Took cold in August. Cough, mucopurulent sputa, pains in the side, emaciation, night sweats. Continued to work till September 15th, when he had an abundant hæmoptysis. Expectoration of blood every day for three weeks. Entered Cochin Hospital, October 7th. Became somewhat better; gained a little in flesh; some hæmoptysis at times. Respiratory murmur much enfeebled behind and on the left, with jerky inspiration and prolonged expiration; on the right, a few, dry, crackling râles after coughing. Breathing sounds nearly normal in front. He was injected with two milligrammes, December 4th at 11 A. M. Temperature did not reach 38° C. The only sign was a rather abundant, white, frothy, mucous expectoration, which adhered to the vessel, with a few annular greenish sputa. December 6th four milligrammes. No fever heat. In the evening, numerous moist cracklings were heard on the right side. The stethoscopic signs on the left side were also more marked. At 7 o'clock next morning, abundant expectoration with the same character as above mentioned. Same auscultation signs. Maximum temperature 37.6° C. Appetite impaired. This patient did not feel as well after the injections as before, and the local signs were increased; examination of the sputa has revealed a few bacilli.

The second patient was one of lupus and was characterized by considerable local and constitutional reaction from the very first.

CASE II. A female patient affected with lupus of the face for four years, was injected twice with two milligrammes of Koch's fluid. In the course of six hours after the first injection there was a lively local reaction, the lupus became swollen and hyperemic; and there was an abundant, thick, yellowish discharge, followed by scabbing. An inflammatory swelling spread around the diseased point, and awakened to action an old dacryocystitis which began to suppurate. After the second inoculation, made forty-eight hours after the first, the reaction was still more marked; the temperature of the patient rose to 40.1° C., and there were chills. The local signs were of the same nature as after the first injection, but only more intense. No very marked fever, the general results have thus far been noted. We did not wait until the congestive signs have abated before we make another injection.

CASE III. A man, twenty-nine years of age, who had had claps of the testis for nineteen years. Two inoculations the first with two, the second with four milligrammes. After the first inoculation the reaction did not make itself felt until at the end of twenty hours; the patient felt starting pains in the lupoid region, and there was a local change. What is of most interesting that the treatment has awakened in this patient paroxysmal dyspnoea. Onset of coughing and mucopurulent expectoration. Second inoculation, reaction came on more slowly.

CASE IV. A man, aged fifteen years. No hereditary antecedents. Took cold in July 14th, a cold, rather

abundant hæmoptysis. Entered Cochin Hospital in November. No very marked symptoms; a little dullness and loss of elasticity on the left side; prolonged blowing expiration; a few crackling râles after coughing. Injection, December 6th, with one milligramme. In the evening the temperature rose to 38° C. Stethoscopic signs above indicated were much more pronounced. The same fact was noted next day and the day following.

CASE V. A man, aged forty-five, sick only since last September. Presents only the signs of commencing tuberculosis. A shade of dullness at right apex posteriorly; here the respiration is harsh, with slight crackling sounds. The patient complains of a little hoarseness. Examination of sputa reveals a notable quantity of bacilli. First injection; one milligramme of Koch's fluid. Reaction after six hours; general malaise; fever (38.4° C.). Hoarseness more pronounced; all pulmonary sounds intensified. On the right, the respiration is blowing over a much greater extent, and numerous moist crackling râles are heard. Second injection, two milligrammes. The pulmonary symptoms continued to be intensified. Laryngoscopic examination showed much congestion of the vocal cords. We shall continue these inoculations, and shall hope for more definite results.

We now know that Koch's fluid is a reagent which has an excessively powerful influence on tuberculous lesions, and even in extremely small doses, so that it is not altogether a *safe* remedy. It is, in fact, a toxic substance, whose effects resemble much what we observe after the inoculation of certain septic products; the same malaise, the same nausea, the same inflammatory reactions. Hence you see the possibility of serious and even fatal accidents attending these injections, especially when the commencing injection has been too large.

[At one of the "conferences," Dr. Ley gave an account of his visit to Berlin, of the properties of the wonderful "lymph," the mode of preparation and dilution for injections, the kind of syringe used, and the manner of injection. All this is sufficiently familiar to the readers of the JOURNAL. The latter part of Dr. Ley's communication at one of these "conferences," however, was occupied with a description of the sanatorium of Falkenstein, which he had visited; the statement which he gives of the trials made with Koch's method at this sanatorium is of sufficient interest to be reproduced in its entirety.]

The sanatorium of Falkenstein, built at a distance of several leagues from Frankfort, at an altitude of 1,100 metres, is situated on one of the most picturesque locations of the Taunus. It is an establishment designed for the treatment of pulmonary tuberculosis by what may be called the "open-air cure," scarcely any medicine being given. The two great features of the establishment are *life in the open air* the greater part of the time, from 9 A. M. till 10 P. M. (meal times excepted) and scrupulous attention to hygiene.

I arrived at Falkenstein the first day of December, and by the kindness of Dr. Dettweiler, founder and director of this establishment, was enabled to watch the treatment of a great number of patients by Koch's new method. The injections with Koch's fluid had been going on for a fortnight; the patients were one hundred and thirty-three in number. All were pronounced cases of tuberculosis with bacilli in the sputa. The quantity of fluid used for each first injection was one milligramme; afterwards the dose was raised to two or five milligrammes, as the case seemed to require.

The reaction was not the same in all. In three of them the temperature rose to 40° or 41° C.; in nine it remained between 39° and 40°; in ninety-eight it kept between 38° and 39.5°; in eighteen it did not exceed 38.5°, and in five the reaction was insignificant, being scarcely if at all above the normal.

After the second injection, made at the end of forty-eight hours (one milligramme), in three-fourths of the patients, in whom a powerful reaction had followed the first injection, the temperature did not exceed 39°, while a certain number of those who had resisted the first injection, had chills and a temperature higher than that of the previous reaction, may this be due to the accumulation of the remedy, thus justifying Koch's recommendation to make the injections with intervals of several days and proceed tentatively before augmenting the dose.

All these patients presented phenomena of temporary congestion; aggravation of the cough, a notable augmentation of the expectoration after the first injections; later on, perhaps by reason of their having become accustomed to the injections (the true explanation has not yet been given), the reactional symptoms were almost nil. The expectoration diminished considerably and almost all expressed themselves as feeling better; this was the case with patients who had received six or seven injections.

There is another category of patients whose condition presents great interest. Dr. Mauritz-Schmidt, an eminent laryngologist of Frankfurt — now at Falkenstein — showed me twenty-three subjects affected with laryngeal tuberculosis in different stages; in all the injection produced a recrudescence of the morbid symptoms. In several of these patients, who previously had been treated by curetting and lactic acid, and who had been considered as cured, the injection of one or two milligrammes showed that this was not the case, and caused a reawakening of the disease.

I saw three who were under treatment for tuberculous infiltration of the apices of the lungs, who had never experienced any laryngeal symptoms, and in whom one milligramme sufficed to cause hoarseness of the voice, thickening of the vocal cords, and revealed the presence of tubercle granulations existing in a latent state.

By continuing the treatment, an improvement is quite rapidly obtained. The tubercle granulations become detached at the end of seven or eight days after the third or fourth injection; in their place, we see at first a sort of grayish and glairy coating which gives place to a lively redness in which may be seen cropping out little granulations of a healthy nature; then cicatrization rapidly takes place. Among the subjects whom I had the opportunity of examining with Dr. Mauritz-Schmidt, there were some at various stages of this evolution-process, according to the chronicity or gravity of the affection and the number of injections received, and I had a good opportunity to watch the progress under the treatment.

Two other cases seem to me worthy of being put on record. The first is that of a young man, twenty-seven to twenty-eight years old, with a slight tuberculous ulceration on the right ary-epiglottidean fold. An injection of two milligrammes caused, besides swelling of the diseased region, a congestion of the mucous membrane of the right nostril which extended to the lacrymal sack and to the conjunctiva of the right eye.

The second patient was a Paris physician who for two months has been trying the open-air treatment and was getting along well, having all the appearances of health; was able to walk without getting out of breath, slept well and had a good appetite, and never had any laryngeal trouble. He remained insensible to the two first injections of one and two milligrammes; a third injection of five milligrammes having been made, this patient was taken five hours afterwards with all the symptoms of a violent reaction; chills, nausea, vomiting, dyspnoea, elevation of the temperature, then severe pain in the larynx and loss of voice.

The next day on laryngoscopic examination, we noticed the existence of a tuberculous process in the larynx, a granulation mortified, and fell off about the sixth day. When I saw the patient, the voice was still very husky, and although he had not received any new injection, he was still under the influence of the medicament; he was easily put out of breath, was pale, slept badly, had no appetite, and had lost five pounds of flesh within eight days.

If, as you see, these facts prove to a demonstration the great diagnostic value of Koch's remedy, they also show the uncertainty under which we still rest as to the therapeutic value of this remedy, and the necessity of the utmost prudence and caution in its use.

The doses at the commencement must be very small, and should be very gradually increased, with intervals of suspension to enable us to take account of the particular susceptibility of each patient. That we are justified in entertaining great expectations of this new method of treatment, I fully believe.

### A CASE OF SUPPURATING UNILOCULAR HYDATID CYST OF THE LIVER, WITH MULTIPLE HEPATIC ABSCESS.<sup>1</sup>

BY FREDERICK C. SHATTUCK, M.D.,  
Professor of Clinical Medicine, Harvard University; Visiting Physician to the Massachusetts General Hospital, etc.

JUNE 23, 1890, I first saw Miss B., twenty-three years of age, through the kindness of her physician, Dr. Fauce, of Sandwich, she having come up from the Cape that morning. Her family history was unimportant except that her father died of Bright's disease. I understood that she had never been out of New England except on an occasional visit to New Brunswick; but subsequently learned, on further inquiry, that up to the age of four years she had sailed over much of the world on the ship of which her father was the captain. Her health through life had been good save for occasional attacks of "indigestion," characterized by epigastric oppression and flatulence, often accompanied and relieved by vomiting, generally traceable to carelessness in diet. Early in April last she had one of these attacks which differed in no way from previous ones except in being more severe and prolonged. She has had none since. This was soon followed by a serious head cold attended with much prostration, and this by a cough with white expectoration. Although she lost strength markedly she did not give up or take to her bed. May 24th she was seized by a

<sup>1</sup> Read before the Boston Society for Medical Improvement, November 10, 1890.

sudden and intense pain in the right side, apparently over the liver, and in the right shoulder. Any attempt to cough rendered the pain intolerable. The localization of the pain remained the same for some time, but it gradually became less severe and shifted about from one place to another, being sometimes felt on the left side. Since the above data she has lost flesh as well as strength, and has had diarrhoea off and on. Recently she has had several chills without periodicity.

June 20th, she had very severe pain across the lumbar region, especially on, but not confined to the right side. The catamenia have not appeared for eleven weeks. The urine for the past fortnight is reported as scanty and of a peculiar yellow color. No history of jaundice was obtained.

She was evidently fatigued by the journey to Boston. Pulse 120, small and regular; respiration somewhat quickened; temperature  $103.5^{\circ}$ ; complexion sallow; no icterus. A careful physical examination, repeated the following morning, was negative except as follows: Moderate dullness with diminished vocal fremitus and vesicular respiration over the lower portions of the right chest, especially laterally and posteriorly. Flatness began at the fifth rib in the mammillary line and extended somewhat below the right costal border and into the epigastrium. Friction sounds were to be heard over the dull area near the anterior axillary line. Change of position by the patient caused no change in the percussion lines. The apex beat was in the fourth space, inside of the mammillary line; the abdomen was full and resonant, quite tender at the epigastrium and at a point above the navel and between it and the left costal cartilages; the edge of the liver could not be felt below the rib margin and I was unable to determine whether the dullness there was due to the liver or some other cause. The area of splenic dullness was increased, but the organ could not be felt. The appearance of the urine was suggestive of the presence of bile pigment, yielding a yellow foam when shaken. A specimen taken the next day for analysis was much less bilious-looking, but gave the reaction for bile pigment. The specific gravity was 1.026; reaction acid; albumen a very slight trace; the sediment contained some blood, chiefly normal; a few leucocytes; and a few doubtful small hyaline and granular casts.

During the night of the 23d she had sudden and severe pain in the left back, relieved by morphia; the next day the fever was less, and the morning of the 25th the temperature was normal, the patient seeming to be doing well in other respects. In accordance with my request Dr. Faneuse came to town that day and we examined the patient together. The surgical aspects of the case were carefully considered and it was deemed clear that there was no indication for any operation at present, at all events. I attributed the signs in the right chest to pleural thickening and believed that there was also some obscure affection of the liver, perhaps a gall-stone which was causing ulceration. The absence of jaundice showed that there could be no notable obstruction of the common or hepatic ducts, and no distention of the gall bladder was made out though it was sought for. If a gall stone was the source of the trouble it was, therefore, probably in a moderate sized duct. The next day there was a return of fever and a chill. The morning of the 27th her condition did not appear altered and it seemed wise to move her from the home to St. Margaret's. The move was accomplished that afternoon. That night she began to fail

rapidly. Dr. Porter saw her with me early the morning of the 28th; about noon she died, the failure in the last twelve hours having been extremely rapid.

The return of fever without obvious cause, and the occurrence of chills in conjunction with the other symptoms and the physical signs led one to modify my first diagnosis and to believe that hepatic abscess was present, impacted gall-stone being the most probable cause. The large amount of bile pigment which was apparently present in the first specimens of urine I saw, led me, in the absence of icterus, to query whether a fistulous tract could have been opened between the biliary and the renal passages.

The autopsy was made by Dr. E. M. Greene, three hours after death. For the sake of brevity negative results are omitted from Dr. Greene's report.

*Lungs* collapsed readily. The upper portion of the right pleural cavity partly obliterated by old fibrous adhesions. On section the lungs showed nothing abnormal.

*Stomach and bowels* considerably distended with gas but otherwise normal.

*Liver* at least twice the normal size, the increase being most marked in the right lobe. The upper surface of the right lobe was united by recent, soft, fibrous adhesions to the diaphragm. The upper surface of the left lobe showed numerous irregular grayish patches size of thumb-nail and smaller. Section through these patches showed numerous superficial abscesses varying in size from a robin's egg to a pea. The purulent contents of these abscesses were frequently tinged with bile. Similar small abscesses were distributed throughout the left lobe. The right lobe was almost entirely transformed into a large, rounded cavity, the wall of which, over the upper half, consisted of the thickened peritoneal covering of the liver, while below the cavity a thin layer of liver-substance still remained. The inner surface of the cavity was lined with thickened fibrous tissue to which irregular layers of fibrin were adherent. The cavity contained more than a litre of thick, opaque, greenish, foul-smelling fluid and a large number of free cysts varying in size from a small hen's egg to a pea or smaller. The wall of these cysts was a thin transparent membrane and their contents consisted of clear, pale yellow, gelatinous fluid. From the bottom of the cavity there led a sinus about ten centimetres in length extending to the duodenum and sufficiently large to admit the forefinger. The lower end was closed. Into this sinus, which consisted apparently of the dilated hepatic and common ducts, the cystic duct, also dilated, entered. The gall-bladder was dilated to several times its normal size and projected considerably beyond the border of the liver. It contained about 200 centimetres of fluid similar to that in the larger cavity.

*Spleen* about twice the normal size, soft, and, on section, of a dark red color.

*Diagnosis:* Suppurating hydatid cyst of liver; multiple hepatic abscesses; acute circumscribed perihepatitis.

It will thus be seen that the clinical diagnosis of hepatic abscess was confirmed; but that its cause was quite different from that which had been supposed, while the enlargement of the liver and gall-bladder was greater than the physical signs had led me to believe. The signs at the base of the right chest, which I attributed to pleural thickening, were really due to the hepatic enlargement, and the friction sounds originated

below, not above the diaphragm — perihepatitis at the superior surface of the liver.

In cases of mistaken diagnosis it is profitable, at least to the attendant, to consider whether the mistake could have been avoided. In this case two questions are brought prominently forward.

(1) Should a more accurate diagnosis have been made?

As far as the presence of so much enlargement of the liver is concerned, I think this question must be answered in the affirmative. And yet, the enlargement being chiefly upward, there was a close simulation of the remains of a pleurisy. Flatness extended somewhat below the costal border, but one must be careful not to attribute this to the liver, unless the edge of the organ, or its surface, can be felt, provided that palpation is not rendered nugatory by tenderness. The enlargement of the gall-bladder at the autopsy was a surprise to me. I can only say that I sought for it, as one would naturally do in a case where, in the absence of icterus, symptoms suggestive of serious disturbance consecutive to gall-stones were present. In order that an enlarged gall-bladder may be palpable, the abdominal wall should be more or less lax — certainly not rigid — and notable tenderness should be absent.

While I am inclined to think that thus far I should, perhaps, have come to more accurate conclusions, I think there are satisfactory reasons why the underlying cause of the hepatic and cystic enlargement was not determined. Echinococcosis disease is rare in this country, and this is the first case which I have seen in life here or elsewhere. The liver, and the right lobe of that organ, is its most frequent seat; the characteristic signs are chronic hepatic enlargement, often local, for which no other obvious cause can be assigned, combined with fluctuation or elasticity and the hydatid thrill; the clinching evidence is furnished by the non-albuminous fluid — if the cyst has not suppurated — containing booklets, withdrawn by puncture.

In this case the cyst was hidden beneath the ribs and costal cartilages, precluding the detection of fluctuation or thrill. I seriously entertained the question of puncture, but decided to wait until the patient was more suitably lodged, or the local indications seemed more clear. The case was only under observation four days and a half. In the "Index Medicus" I find only thirteen cases of liver hydatid reported in this country and Canada, 1880-1890; of these, nine were diagnosed during life, the other four being found post-mortem. In the nine the enlargement was either local or very great. The only other clinical observation of liver hydatid in Boston, of which I have cognizance, was a City Hospital patient with a very large suppurating cyst of the upper surface of the liver, extending far up into the thoracic cavity. Aspiration gave pus, and empyema was diagnosed. Dr. Bradford made a free incision, through which the daughter cysts escaped in large numbers. The patient survived only a few days.

(2) In this case, if a correct diagnosis had been made, could life have been saved?

This question can be unhesitatingly answered in the negative. The right lobe of the liver was nearly destroyed by the cyst, the left lobe was riddled with small abscesses; drainage of the former would not have affected the latter.

For some reason, which is not clear to me, hydatid

disease seems to be quite common in Australia, and the Australian *Medical Journal* for 1888 and 1889 contains a very interesting and complete discussion of the operative treatment by Dr. Thomas. It is impossible here to do justice to his paper. Suffice it to say that he advocates incision by Lindemann's method; believes many of the reported cures after simple aspiration to be illusory; considers suppurating cysts especially unsuited to aspiration; and states that unruptured cysts of the convexity of the liver present great difficulties in their successful treatment, inasmuch as thoracic incisions show a high rate of mortality.

#### FURTHER OBSERVATIONS ON PERMANENT TUBAGE OF THE ESOPHAGUS.<sup>1</sup>

BY S. J. MIXTER, M.D.

Surgeon to Out-patients, Massachusetts General Hospital; Visiting Surgeon, Carney Hospital; Demonstrator of Anatomy, Harvard Medical School.

SOME months ago I had the honor of reading before this Society a paper on Esophageal Tubage.<sup>2</sup> Since that time I have had the opportunity of observing and treating some of the cases then reported, as well as others. I have noticed several interesting points in connection with their treatment, and I have devised some new instruments for the introduction of the tubes, which is my reason for presenting the following paper.

First, I wish to speak of the subsequent history of two of the patients (Cases III and IV) mentioned in the previous article. The first of these wore a tube almost constantly, never being more than two days without one, until his death early in October. There was no trouble from the presence of the tube, and the patient gradually became weaker, suffering some pain in the chest and having the usual troublesome cough during the last few weeks. One very interesting point in connection with this case as well as with some others, is, that on leaving the tube out for even a day the stricture closed and no food could be swallowed. On trying to introduce another tube the greatest difficulty was met with in passing even the guide into the stomach, and a smaller tube had to be used for some days. This patient came to my office about three weeks before his death, a distance of about thirty miles — unfortunately no autopsy could be obtained.

The other (Case IV) is still under treatment, and is now in very fair condition, as may be seen. (Patient shown and tube changed, the instruments further on described, being used.) This man, I have lately learned, was in one of our hospitals just before I saw him first, and as no instrument could be passed through the stricture, he was fed by the rectum, and a gastrostomy was proposed. As he objected to the performance of an operation, he eloped, and soon after appeared at my clinic as previously stated. That was in April, and recovering his strength after wearing the tube a short time, he has been able to work ever since, earning enough to support himself, something he surely could not have done after a gastrostomy.<sup>3</sup>

I have reported these cases at length as they show perfectly the slight inconvenience caused the patient

<sup>1</sup> Read before the Boston Society for Medical Improvement, November 10, 1890.

<sup>2</sup> See vol. cxliii, No. 17, of this Journal.

<sup>3</sup> This patient has worked regularly up to a week ago when he gave up on account of weakness and entered the hospital, where proper and sufficient food seen to have given him a new lease of life, much to his and our surprise.

by the tube, and the prolongation of life with comparative comfort. The contrast between the results obtained by tubage and by gastrostomy is so great that I am convinced that the latter operation should never be performed until repeated attempts to pass suitable instruments have failed. If any instrument, however small, can be introduced, the patient can probably be made comfortable for the rest of his life without a serious operation.

Manufactured by Colman and Shurtleff, Boston.

This brings up the question, What are suitable instruments to use in difficult strictures? I was unable to find anything in the shops in this country, nor could they be found in England, at once safe and effectual, and therefore I devised the guide mentioned in the previous paper. This I have improved, and as now made for me by Colman and Shurtleff (who have made the instruments and imported the tubes that I have used), consists of a whalebone staff, on the end of which can be screwed flexible bougie tips of different sizes, from a child's to about a number 6 or 7 F. These tips are one and three-quarters to two inches long, and at the upper end are slightly stiffened by means of a fine spiral spring inside. The instrument, therefore, does not require a urethral guide. This I have been able to pass where all other instruments failed. When larger instruments will pass, olive-pointed bougies can, doubtless, be used; but the urethral form, make a most perfect guide for the passage of the larger tube, open at the end.

During the past month I have received from England tubes and instruments of various patterns. Among the tubes were some considerably shorter than those that I used, being four inches long instead of five and three-quarters, and in no respect the short one seemed to be better. Some of them were open at the end and were very difficult to get at all constructed. These I have found in every way the best form, and on a study of a table, viz., one nearly filling the

tube, can be passed easily and safely. I have even cut off the ends of some of the longer tubes and found them perfectly satisfactory.

It is often difficult to tell whether the tube is through the stricture, and therefore I had stamped on the metal staff of my bulb bougies a centimetre scale, and a similar scale is stamped on the staff of the introducing instrument.

When the tube is forced into its place by means of a probing, the latter often is so firmly held by the funnel-shaped top of the tube that on withdrawing it, the tube is brought with it. The use of the probang for this purpose renders it difficult to use a suitable guide; to overcome these difficulties I made from a piece of brass tubing and a wire, an instrument similar to the one shown in the cut. The method of using will be readily seen. The guide being passed into the stomach, the tube and introducer are passed over it, the string attached to the funnel being passed through the introducer, which is firmly pressed into the tube carrying the strings in the notches on its end. The tube is then passed to the correct distance as measured by the scale and after withdrawing the guide the staff is held firmly with one hand while the string is pulled with the other. This always frees the introducer from the tube, which remains in place after withdrawing the former, however lightly held by the stricture.

With the above improvements in the tubes and methods of introduction, permanent tubage of the oesophagus is a most satisfactory and simple method of treatment.

## THE ETIOLOGY OF LATERAL CURVATURE OF THE SPINE.<sup>1</sup>

BY ROBERT W. LOVETT, M.D.

THE etiology of scoliosis, the subject assigned to me by the President, is not one which can be made original or interesting, and brevity is the only merit attainable. In no department of orthopedic surgery has the modern change of opinion been more noticeable than in regard to lateral curvature of the spine and its time of appearance. Formerly regarded as an affection beginning at, or about, the time of puberty,<sup>2</sup> it has been shown by investigation to be a deformity of much earlier life than had been supposed. I need only call your attention to the well-known figures of Ketch and Eulenburg.

Ketch,<sup>3</sup> in 229 cases from the New York Orthopedic Hospital and Dispensary, found that 52% began between the first and twelfth years, 41% between the twelfth and eighteenth years and only three or four per cent. after the eighteenth year.

Eulenburg<sup>4</sup> analyzed 1,000 cases of scoliosis and found them distributed as follows:

Before the second year . . . . .	5
Between the second and third year . . . . .	21
"    third and fourth year . . . . .	9
"    fourth and fifth year . . . . .	10
"    fifth and sixth year . . . . .	33
"    sixth and seventh year . . . . .	210
"    seventh and eighth year . . . . .	561
"    eighth and fourteenth year . . . . .	107
"    fourteenth and twentieth year . . . . .	28
"    twentieth and thirtieth year . . . . .	7

<sup>1</sup>Read at the American Orthopedic Association at Philadelphia, September 1, 1890.

<sup>2</sup>New York Medical Record, April 21, 1882.

<sup>3</sup>Proceedings, American Orthopedic Society, 1885, Noble Smith: The Surgery of Deformities, 1887. The Pathology and Treatment of Lateral Curvature of the Spine, 1888.

<sup>4</sup>The Sittichen Rückenmarks-Verkrümmungen, Berlin, 1876.

In short, 85.8% of all cases occurred before the tenth year.

Congenital cases are described, although they are rare and most apt to occur with congenital rickets or in anencephalous children and the like.

Sex exercises a very marked influence, which is not altogether to be accounted for, because, as we have just seen, most cases occur before sexual characteristics are very well marked. Consequently the enormous preponderance of girls among those affected with lateral curvature finds no very satisfactory explanation, beyond the fact that their growth is more rapid than that of boys, and in the city, at least, in their growing years the conditions are not such as to favor their muscular development. Nevertheless, this hardly seems enough to explain the very much larger number of girls affected.

Vogt explains a certain part of this in calling attention to the fact, that, if parents were as solicitous about the figures of their boys as they are in the case of their girls, the proportion of males would be much larger than it is.

The proportion of boys to girls is variously estimated. Eulenburg would set it as ten to one, Drachman as four to one, Kölliker as five to one, etc. Adding together the groups of cases reported by Adams, Kölliker, Ketch, Roth, Behrend and Wildberger one finds 1,974 girls and 365 boys, giving a proportion of about five girls to one boy, which fairly represents the proportion of cases as seen by the surgeon.

No factor is more important than the general health of these patients. As a rule, they are distinctly below the average in muscular development, and in vigor of circulation they leave much to be desired. They are prone to intercostal neuralgias, the digestion is likely to be feeble, the hands and feet are cold, and in some instances, at least, the curvature is associated with defects in one or both eyes. Very often one sees cases of lateral curvature where the muscular development is decidedly above the average but they are exceptional, and although, as a rule, the lack of good condition in cases of lateral curvature is not extreme, it is generally so well marked as to be noticeable.

The influence of heredity is sometimes mentioned as a factor in the production of scoliosis, but it seems doubtful if it plays a very important part in predisposing to the disease, more than by transmitting a general feebleness of development. Mr. Adams would class all cases occurring under twelve years as hereditary, and Eulenburg considers nearly a quarter of all cases as such, but it seems to be on insufficient evidence in both instances.

Rickets or a similar affection is advocated by many writers as the cause of most cases of lateral curvature. But apart from the cases which are manifestly rachitic in the general involvement of the bony system, the other cases of scoliosis show no evidences which can bring them legitimately under the head of rickets. Epiphyseal enlargements are not present, bony changes elsewhere than in the back are not to be found and the history of the child gives no account of late dentition, delayed closure of the fontanelle, sweating, or any of the classical symptoms of rickets. It is evident, therefore, that if these cases are rachitic the process is an anomalous one and is not characterized by the usual diagnostic signs. The pathology of the future may show a bony affection in lateral curvature which is similar to what we know of rickets. But for the

present to speak of cases of scoliosis as rachitic where the signs of that affection are absent, is an assumption entirely unjustifiable from a scientific point of view, and entirely unsupported by anything beyond personal opinion.

So far, the factors that have been mentioned may be classed as predisposing causes of the affection. In turning to the more immediate causes one finds certain cases where it is plainly evident what caused the curvature, but in the majority of cases the cause lies hidden in the deepest obscurity, as is made evident by the many fanciful reasons adduced to account for the condition.

Among the cases where the cause of the lateral curvature is evident may be classed those resulting from

- (a) Empyema.
- (b) Infantile paralysis.
- (c) Cerebral paralysis.
- (d) Hereditary locomotor ataxia, and muscular pseudo-hypertrophy.
- (e) Rickets.
- (f) Pott's disease.
- (g) Certain cases from occupation.
- (h) Various miscellaneous cases such as those caused by the loss of an arm, etc.

It is hardly worth while to comment upon the very obvious way in which any one of these may cause lateral curvature (except in class (d) where it can only be said that scoliosis is very commonly found). It will, therefore, be better to pass on at once to the larger and much more obscure class where no such evident causes are to be assigned.

It hardly seems worth while to take up your time with a catalogue of the theories which have been advanced to account for the occurrence of lateral curvature. Their number is legion and most of them have only to be mentioned to be dismissed. A fairly complete list of them may be found in Reeves's "Practical Orthopedics." Three classes of theories meet with acceptance to-day. (1) the muscular theory, (2) the osseous theory, (3) the superincumbent weight theory.

(1) The muscular theory finds the cause of lateral curvature in the unequal action of the muscles on the two sides of the vertebral column. The idea of Guérin is no longer tenable, that an active unilateral muscular contraction is the cause of the trouble. Stromeyer and Barwell speak of contraction of the serratus magnus muscle as being the disturbing factor. But clinical evidence is wanting to support such views, for, as far as can be seen in early cases, the muscles of the two sides react alike to all tests to which we can put them, and evidences of active muscular contraction are not to be found.

In the modified form of the muscular theory identified with the name of Eulenburg there is much that is satisfactory. He states that inasmuch as continuous muscular effort is necessary for the maintenance of the erect position, it happens if any of the muscles are weakened and fail to do their work, that the spinal column will bend and assume a faulty position, thereby stretching and still further disabling the muscles already weakened. In this way the assumption of the same bad attitude will in time lead to a permanent curve.

Evidence is wanting, as has been said, to show primary weakness or contraction of the muscles of one side in early scoliosis, especially as to electricity the re-

action is the same. Moreover, there is no reason to suppose that a slight stretching of the muscles is so important a factor in weakening them. Nevertheless, although this theory cannot be accepted as the explanation of all cases or perhaps as the sole cause of many, it does at least serve its purpose in calling attention to the importance of muscular weakness as a factor in the production of lateral curvature.

(2) The theory of abnormal bony growth has less to commend it. Huter and Engel believe that one side of the chest grows faster than the other, and that the ribs ossify prematurely, contributing to the distortion. Such changes are not, however, found in early cases; and, moreover, the flexibility of the column and the disappearance of the curve during recumbency would tell seriously against the theory if it were worthy of serious refutation.

Lorinser would account for scoliosis as the result of subacute inflammatory changes in the bone. Many writers, especially of late, speak of rickets as the cause, a question which has been already dealt with. And many modifications of this osseous theory might be catalogued if it seemed profitable.

(3) The third theory would find the cause of scoliosis in superincumbent weight falling upon a spinal column which was obliquely held. It is to this last view that the weight of modern opinion is continually tending. Certain anatomical experiments were undertaken by Dr. Bradford,<sup>5</sup> four years or more ago to ascertain whether the changes found in true scoliosis were such as could be produced by superincumbent weight alone. It was found by a series of experiments upon the cadaver that when downward pressure was made upon the spinal column held in an erect position, a backward bending of the spine took place which became a lateral curve when a certain point was reached, reproducing the features of a true scoliosis, including the typical rotation. Several experiments showed the same point. In the course of these experiments it was found to be practically impossible to prevent the weight used from coming somewhat obliquely upon the column, and the more obliquely it came the more marked became the scoliosis. What these experiments showed was that superincumbent weight can cause rotary lateral curvature when falling upon a spinal column held even a little obliquely. This at first a physiological affair, becomes quickly pathological on account of the pressure changes which result.

It is easy to see how, in connection with a certain amount of muscular weakness, this comes about, and especially how lateral curvature is favored by the existence of a short leg or the assumption of faulty attitude which tend to render the pelvis oblique, but it is evident that there is some other factor to be considered, for short legs are surprisingly common and true lateral curvature is not associated with more than a very small minority of them. The frequency of short legs may be appreciated from the following figures: "Morton" measured 443 healthy boys, and found 27 with inequality in the length of their legs; and Cameron, of London, in measuring the leg bones of 4000 healthy, found the lower limbs of equal length in only ten per cent. It would seem, therefore, that the importance of a short leg in the production of lateral curvature had been overestimated. The same is, in a

manner, true with regard to the assumption of faulty attitudes, which in only comparatively few instances are followed with lateral curvature.

In concluding this very hasty summary of opinions, the writer can only join with you in regretting that nothing more tangible or more definite can be offered.

## RECENT PROGRESS IN DISEASES OF THE NERVOUS SYSTEM.

BY PHILIP COOMBS KNAPP, A.M., M.D.

### NEURALGIA.

*Sciatica.*—Guinon and Parmentier<sup>1</sup> describe a complication of sciatica not usually recognized. This complication, which is rather serious and gives rise to an unfavorable prognosis, consists of a neuritis localized in the external popliteal nerve, and associated with degenerative atrophy of the muscles supplied by it. This neuritis is attended with motor and sensory disturbances in the distribution of the nerve, paralysis of the extensors of the foot and toes, and anaesthesia to pain, temperature, and touch over the dorsal surface of the foot and the external surface of the lower leg. With the paralysis there may be more or less atrophy of the affected muscles with more or less complete reaction of degeneration. This particular complication has been recognized previously in the cases of injury to the sciatic during labor, from pressure within the pelvis, and various writers have endeavored to explain it on anatomical grounds, claiming either that the external popliteal was a direct continuation of the sacro-lumbar trunk, or that the sciatic divided anomalously high up in the pelvis. Guinon and Parmentier, having demonstrated that this localized neuritis is occasionally found in ordinary sciatica, doubt both these hypotheses, and are disposed to believe that the reason of this special selection of a single branch is as yet undetermined, although they admit the possibility of an analogy with the greater predominance of extensor paralysis in lead-poisoning and other peripheral affections. When this trouble occurs the case is apt to be protracted, lasting two or three years, and a cure is difficult and often impossible.

Brissaud<sup>2</sup> has made a further study of the attitude of patients with sciatica, described some time ago by Babinski. He finds not infrequently a "sciatic scoliosis," a curvative of the spine with the convexity toward the affected side. The leg is also slightly flexed, and is supported on the toe. There is often a compensating curvature of the spine higher up. This position is sometimes of service in diagnosis in the early stages of the disease, and the contraction sometimes persists after recovery. It is due simply to the effort which the patient makes to keep the weight off the affected leg. In a few cases, however, there is contraction of the muscles on affected side, causing the convexity on that side. This is due to spasm, and is seen where the neuralgia is not limited to the sciatic nerve, but affects other nerves in the sacro-lumbar plexus.

G. M. Hammond<sup>3</sup> opposes the view that rheumatism, syphilis, or gout have any importance in the etiology of sciatica. He advocates three measures in the treatment—rest, cold, and electricity. Rest is obtained by a long splint, from the axilla to the ankle, applied

<sup>3</sup> Journal of Nervous and Mental Disease, May, 1890.

to the external surface of the thigh. Cold should be applied by ice-bags along the course of the nerve. Galvanism should be used, a very large negative electrode over the sole of the foot, and another large electrode, positive, over the gluteal region at the point of exit of the nerve, using as strong a current as the patient can bear, and avoiding interruptions. Other treatment was merely symptomatic.

*Treatment of Neuralgia.*—Leslie<sup>4</sup> gives a method for the treatment of trigeminal neuralgia and odontalgia which he claims has given brilliant results in forty out of forty-five cases. It is simply the application of powdered table salt, chloride of sodium, to the nasal mucous membrane. It acts almost instantly: he thinks it a reflex inhibition of the pathological process.

Rose<sup>5</sup> reports the removal of the Gasserian ganglion for inveterate trigeminal neuralgia. The patient was a woman of sixty, with intense neuralgia in the right inferior maxillary nerve. In August, 1888, he stretched the nerve, which gave relief for a time. In March, 1889, he excised half an inch of the nerve, which gave partial relief, but the pain gradually increased, becoming intolerable, and involving the tongue. In March, 1890, he cut the dental and lingual nerves, but the pain increased in severity, extending to the cheek and upper jaw, so that soon after he removed the superior maxilla, trephined over the foramen ovale, and removed the ganglion. Neuro-paralytic ophthalmia set in, destroying the right eye, but the woman made steady progress, and up to October, 1890, remained entirely free from pain. There was anæsthesia of the right cheek, atrophy of the right temporal and buccinator muscles, and loss of taste on the anterior part of right side of tongue, but taste was retained in the posterior part. In future operations he advises stitching the lids together to avoid ophthalmia.

#### MUSCULAR ATROPHY.

Raymond<sup>6</sup> has recently published an exhaustive treatise on this subject. The muscular changes which lead to atrophy are either parenchymatous (affecting the tubes of the sarcolemma) or interstitial (affecting the perimysium, fat, vessels, etc.). These changes may arise primarily in the muscles (myopathic atrophy) or they may develop secondarily to alterations in the trophic centres (myelopathic atrophy) or in the motor nerves leading from these centres to the muscles (neuropathic atrophy). The atrophy may be limited to a single muscle or a group of muscles supplied by the same nerve (circumscribed atrophy) when it is usually myopathic or neuropathic; or it may begin in one muscle, and invade progressively other muscles near or remote (progressive atrophy), a mode common to all forms; or finally a number of muscles may be affected at once, the disease making no farther progress (diffuse atrophy), a form which is probably always myelopathic. Atrophies may arise from some external cause or from over-exertion, from heredity, or from general causes, notably infection or toxic agents. Circumscribed atrophies arise from causes acting directly upon the muscle, injury, inflammation, or joint disease, or they are due to lesions of individual nerves. In the former case the atrophy precedes the paralysis, the sensibility is not disturbed, and the electrical excitability is quantitatively diminished; in

the latter case the paralysis precedes the atrophy, anæsthesia is present, and there is first increased electrical excitability followed by reaction of degeneration. The type of the progressive atrophies is that first described by Duchenne and Aran, which begins as a rule in the small muscles of the hand. This is held to be of spinal origin, not to be hereditary, and to show fibrillary twitchings and partial reaction of degeneration. Raymond is inclined to differentiate this from amyotrophic lateral sclerosis, although he admits the possibility of the identity of the two affections, and owns that many autopsies of pure Aran-Duchenne atrophy, without spastic symptoms, show changes in the white matter as well as in the anterior cornua. Bulbar paralysis and amyotrophic lateral sclerosis he believes to be due to the same process, with different distribution. The myopathic progressive atrophies are often hereditary and begin in youth. Fibrillary twitchings and electrical changes are rare, and the author denies that reaction of degeneration occurs. Pseudo-hypertrophic paralysis is regarded as a distinct clinical type, but the existence of pseudo-hypertrophy to a mild degree in other forms is admitted. The other myopathies, the "types" of Leyden-Moebius, Zimmerlin, Erb, and Landouzy-Déjerine, are regarded as merely different distributions of one affection. The type Charcot-Marie, beginning in youth, affecting the legs first, and being hereditary, resembles the myopathies, but the presence of fibrillary twitchings, reaction of degeneration, cramps and pain, make it more probable that it is of a neuropathic or myelopathic origin. The diffuse atrophies attack a number of muscles at once, but, instead of progressing, the symptoms subside, and some of the muscles recover in part. These are myelopathic, and comprise the common infantile spinal paralysis, the acute anterior poliomyelitis of adults, and chronic anterior poliomyelitis, the existence of which is now admitted, and the general spinal paralysis of Landouzy-Déjerine, which is regarded as simply a modification of acute poliomyelitis. Then comes the atrophy seen in syringo-myelia, with its characteristic complications of trophic disturbances, and with its insensibility to pain and temperature. And finally the author notes the existence of atrophy in hysteria and in cerebral disease, not only in cases of secondary degeneration with invasion of the anterior nerves, but in cases where the anterior nerves were intact. The existence of trophic centres in the cortex, however, he regards as still hypothetical.

#### TABES DORSALIS.

*Etiology.*—Klemperer<sup>7</sup> discusses the question of traumatic tabes. He gives a table of thirty collected cases, and cites four new ones from Leyden's clinique. These cases, he thinks, show clearly that trauma may act as a cause of tabes, even where there is no special nervous predisposition. In these cases it is not infrequently noted that the initial symptom of tabes appears in the injured part. Severe contusions, lacerated wounds or gun-shot wounds seem most apt to give rise to tabes, which may develop within a few days or not until ten years after the injury. Trauma may also often be associated with exposure to cold. It is still hypothetical whether in these cases the changes in the posterior columns may not be secondary to an ascending neuritis, beginning at point of injury, and the author is disposed to admit the possibility of such a process.

toms to give rise to medical treatment, are very rare; but it is not extremely rare to meet with these cysts in the liver, either in a recent condition with considerable quantity of fluid present, or partly cheesy and also partly calcified. I think it is fair to say that I have seen at least a dozen cases of this sort where the liver has contained either the old or recent echinococcus cysts.

DR. G. B. SHATTUCK: The case to which my brother referred at the City Hospital was in my service at first. I had her under observation a short time, and subsequently, when I went off duty, she passed into the service of some one else, and was transferred to the surgical side for operation. While I was on duty I do not think any diagnosis was made. I believe in that case the cyst had ruptured through the diaphragm into the pleural cavity. There was one thing about that woman, as well as I remember, that she was born in Iceland, but had not been there for a great many years. At the time she was in the medical service at the City Hospital I think, as well as I remember, the grounds for making a correct diagnosis were very small.

DR. F. C. SHATTUCK: I do not know where she got this thing. It must have been growing a very long time. Why these things are common in Iceland there seems to be a pretty good reason; but why they should be so common in Australia, I do not quite understand. They seem to be very common there. An Australian gentleman, Dr. Thomas, I think, has written a very elaborate paper on the subject in an Australasian medical journal, advocating free incision in these cases. He thinks many of the supposed cures from simple aspiration are really fallacious: the patients may get better for a time, but oftentimes the disease subsequently recurs. He reports very favorable results indeed, and they report so many cases there that it would seem as if everybody was on the lookout for it.

DR. S. J. MIXTER read a paper on

#### FURTHER REMARKS ON PERMANENT TUBAGE OF THE ŒSOPHAGUS.<sup>2</sup>

DR. HOOPER: How much are these tubes used in England?

DR. MIXTER: I do not know. Symonds reported a large number of cases, and that is the latest I have seen. They are making improvements in them all the time, because I have received several new patterns. I think they have given up using the long tubes, either through the nose or the mouth, except for stricture of the very upper end of the œsophagus. These short tubes of Symonds give the best results.

DR. HOMANS, 2ND: Do these tubes, besides the ease in feeding, also give any relief to the cough which is often one of the most distressing symptoms?

DR. MIXTER: I think not. The cough is probably due, certainly in some cases, to extension into the trachea; and in these cases morphia or something to relieve the cough must be given, but the patients certainly are very much more comfortable.

DR. J. ORNE GREEN showed a specimen of

BONY ANCHYLOSIS OF THE MALLEUS AND INCUS, the incus having been largely destroyed by caries. The specimen is interesting as showing a true bony anchylosis of the smallest articulation but one in the body. It was removed from a boy four years old, who had suffered from a chronic purulent inflammation of the

right tympanum for a long time. The drum-membrane had been destroyed, and a polypoid growth from the tympanic attic (so-called) persisted in spite of long and continuous treatment. As it was evident this was the source of the inflammation, the two ossicles were removed in order to clear out the attic. After their separation two polypi were removed from the attic, and a small spot of caries was found on the inner surface of the outer wall of the attic, the caries and the two polypi being undoubtedly the cause of the persistent otorrhœa. The caries on the incus had been cured, the bone being covered with a healthy membrane.

The operation was done by dissecting away the remnants of drum-membrane from the tympanic ring, performing a tenotomy of the tensor tympani muscle, partially cutting away the ligaments of the malleus and then removing the bones by evulsion. The large destruction of the incus had already disarticulated the stapes.

No reaction followed the operation, but it is too early to speak of the result as yet. It will probably be good, provided no further caries develops.

DR. DRAPER presented

#### A STOMACH, ŒSOPHAGUS AND DUODENUM SHOWING THE CAUSTIC EFFECTS OF A FATAL DOSE OF CARBOLIC ACID.

These specimens came from the body of a woman forty-one years old, who was found dead under somewhat mysterious circumstances, as follows: She was the cook in a well-to-do family, and had been left alone in the house by her mistress, who went to town on a shopping excursion. When the mistress returned three hours later, she found the front door of the house locked, and entered by a side lower door, and was attracted first by seeing wet stains and foot-prints on the floor and stairs of the basement, on the kitchen floor, and on the stairs leading to the attic. She also saw that the ceiling in her bath-room showed a recent wet stain, and going to the tank-room just above the stain, she found the floor wet. She then went to the servant's room, and found her lying dead on the floor, in a perfectly natural position, a pillow under her head, and nothing about the body or room to show anything like disturbance or violence of any kind. The woman's clothing was wet through to her skin, even the flannel under-clothing was saturated. Her hair was wet. On being summoned to the case, and making inquiry, I learned that the woman had been of rather a nervous disposition, and had been depressed in consequence of some family troubles; that her mother and sister had been insane; and that she had talked about the moral side of suicide, and had always expressed herself as strongly against the idea of suicide.

The case was mysterious, because the body had been in the water, and probably in the tank, although on going to the tank and examining it, that seemed almost incredible, because it was uncovered only to the width of about fifteen or sixteen inches and in length about three feet. How she could have got into the tank and out again was not clear. The cause of death, too, was, at first view, a mystery; but on making a post-mortem examination the next day, it was rendered sufficiently clear. The surface of the body, except a stain upon the chin, was perfectly natural. This stain extended obliquely across the front of the chin from the corner of the mouth, and instead of being white, as we are taught it is generally in carbolic-acid poisoning, was

<sup>2</sup> See page 5 of the Journal.

of a dull yellow, resembling closely the stain of nitric acid on the skin. The inside of the lips, cheeks and pharynx was a dead white, and the surface of the tongue showed white with a pasty appearance upon it. The specimens, when taken from the body, showed plainly and strikingly the appearances of the caustic effect of carbolic acid. The lining of the œsophagus was a clear, glistening white, resembling as much as anything the drawn sugar candy of the confectionery shops. The gastric mucous membrane was hardened so that portions of it had a parchment appearance and feel, and the white ridges or rugæ were bleached and granular, as if a thin layer of plaster-of-Paris had been applied. The mucous membrane peeled up readily. This caustic effect showed to some extent in the duodenum, but did not extend below it. The blood was fluid, and of dark red color. The right cavities of the heart were over-distended with blood, the lungs were engorged, and the kidneys were of a dark red color.

With regard to the history of the case, I have no additional data. How much the woman took of carbolic acid, in what form she took it, where she got it, we do not know; but the supposition is, that having swallowed the dose of carbolic acid, concentrated as it must have been, the distress at first was very great, and she attempted to lessen it by jumping into the tank of water; she got out again, and going to the cellar, fell there on the floor; recovering enough strength to go to the attic, she disposed herself in an orderly fashion on the floor, there to die. The diagnosis of carbolic-acid poisoning was made readily by the odor as well as by the anatomical appearances. The contents of the stomach amounted to little less than a pint. The odor of the acid still persists in the specimen, as you observe. The urine in the bladder was normal in color, but of small amount.

The length of time a person lives after taking these large doses of carbolic acid varies very much indeed. The shortest time on record in which death followed the fatal dose is three and a half minutes, and the longest case is forty-eight hours. In the majority of cases, I think death follows rapidly.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED Meeting December 15, 1890, the President, GEORGE T. HARRISON, M.D., in the Chair.

DR. ROBERT C. NEWMAN read a paper entitled:

#### USE OF MODÈS OPERANDI IN THE TREATMENT OF URETHRAL STRICTURES BY ELECTROLYSIS.

He said that it was only almost nineteen years since he commenced his first experience in the electrolytic treatment of stricture, and since that time he had not read a paper on this subject before a New York City Society. Moreover, it seemed to him that this method was less practiced and less understood in New York than elsewhere in the United States. At this time he would not detain the Association with a consideration of the theories relating to the matter. It was only necessary to explain that electrolysis was a chemical decomposition, and that the body to be decomposed must possess certain elements to be an electrolyte, and, as a compound body, must contain water and acid. The action of the poles was very different; the positive pole attracting the acid, and the oxygen

from the tissues and coagulating blood, while the negative pole attracted the alkalies, hydrogen, and the base of the salt, dissolved blood (but formed a plug from froth of the hydrogen), coagulated albumen, and caused absorption. For the immediate destruction of tumors and strictures the negative pole was therefore to be selected, and as we could not trust to the marks of the instrument maker, it was necessary to apply tests in order to distinguish the negative from the positive pole. Among these are the water test and the meat test, and the latter was exhibited. The poles of the battery in the shape of two platinum needles were inserted into a piece of raw fresh meat. After the electrolytic action had been allowed to take place for a while the difference in pole action could be readily observed, the positive pole charring and almost destroying the tissue, while at the negative pole the color was almost white and bubbles of hydrogen could be seen.

In the treatment of strictures the negative pole should be composed of metal, such as brass, copper or silver, and constructed in the form of an egg or acorn-shaped bulb. The positive pole, used here for closing the circuit, should be of large size and made of brass or carbon, covered with sponge or absorbent cotton.

For over twenty years Dr. Newman said he had successfully treated all strictures of the urethra by electrolysis, not having resorted to internal urethrotomy in a single instance. Several hundred cases had been published, and many hundred cases were now on record, while many more, of which no record had been made, had been treated in public institutions.

In practising this method the topography of the urethra should first be well ascertained and the strictures measured. The patient's susceptibility to the galvanic current is to be learned by applying it to the hand or some other part of the body. Anæsthetics are not to be used, because no pain should be caused, and because the patient ought to be conscious, so that he can express his sensations. For ordinary strictures the size of the bougie selected should be three numbers (French scale), larger than the stricture. This bougie electrode is to be introduced until the bulb is arrested by the latter, and a sponge electrode, wet with warm water and connected with the positive pole of the battery, is to be held firmly against the patient's skin (either in the palm of the hand or on the abdomen, thigh, or some other part), to complete the circuit. While the poles are held in this manner the current is to be increased very slowly and gradually, one cell at a time, until the patient feels a sensation of warmth and slight pricking. At the same time the current is carefully measured by means of the milliamperè-meter. The operator should hold the bougie steadily though very gently against the stricture, and he will soon find that absorption is taking place and the stricture yielding. The instrument thus slowly advances until it has passed the obstruction—sometimes it will fairly jump through the stricture. If there are more strictures than one, the bougie should be guided in the same way until it enters the bladder. Then the electrode is to be withdrawn slowly, and each stricture well worked out, until the first stricture is again passed, when the current is slowly reduced, cell by cell, to zero; and not until then is the electrode to be withdrawn. During the whole operation the electrode should be held very loosely, all pressure or force being carefully avoided. In order to show the usual history and progress of the

treatment Dr. Newman gave a report of two typical cases of long standing and great severity in which a cure had been effected; though relapse having occurred after five and three years respectively.

The instruments required were given as follows: One set of egg-shaped bulb electrodes, one set of short, acorn-shaped bulb electrodes, one set of tunnelled electrodes, a number of combination electrodes, *bougies à boule* and filiform guides, a galvanic battery, a milliampère-meter, two carbon-covered handles for electrodes, two or three binding screws, and a few connecting cords. The apparatus should be carefully selected and only the work of the most reliable makers should be used. The regular electrodes for all ordinary cases have a short curve and an egg-shaped metallic bulb at the extremity. He considers a conical bulb objectionable in most cases, as the operator should depend on the electrolytic power of absorption, and not on force. The acorn set of electrodes is for use in the first six inches of the urethra in certain cases, and these instruments are short and without a curve. Sometimes it is desirable to gain ground by entering the contraction first with the point of the electrode, in order to follow more easily with the larger part of the bulb, and as the action of the electrolysis depends on the largest diameter of the latter in these cases, the acorn-shaped bulb does most service during the withdrawal of the electrode, when the operator knows best how much work should be done. The tunnelled electrodes are very important for bad, tortuous strictures, but are to be used only by the expert operator. In them the curve is shorter, and the egg-shaped bulb is tunnelled, so that it can be introduced over a filiform guide. When the stricture is impassable with ordinary instruments the tunnelled electrode can be used successfully, and passed through the stricture without the possibility of making false passages. The combination electrode is a tunnelled electrode and catheter in one, and is used as an auxiliary electrode for extreme cases. When a very tight stricture is complicated with retention of urine the indications are to remove the obstruction and draw off the water with one instrument, as the parts are too sensitive to tolerate the introduction of two instruments in succession. Also the patient may be benefited by washing out the bladder; all of which can be done with one introduction of the instrument. The *bougie à boule* is used for preliminary examinations to detect the strictures and their location.

The following rules are offered as a safe guide for practitioners wishing to adopt the electrolytic treatment of stricture:

(1) Any good galvanic battery will do which has small elements, and is steady in its action. (2) The fluid for the battery should not be used too strong. (3) Auxiliary instruments are important to the expert, but not necessary for the beginner; though a milliampère-meter is now imperative. (4) For the positive pole a carbon electrode is used. It is covered with sponge moistened with hot water, and held firmly against the cutaneous surface of the patient's hand, thigh or abdomen. (5) For the absorption of the stricture the negative pole must be used. (6) Electrode bougies are firm sounds, insulated with a hard baked mass of rubber, and having a bulb at the extremity. (7) The curve of the electrode should be short. (8) The plates must be immersed in the fluid before the electrodes are placed in position. (9) All

operations must begin and end while the battery is at zero; the current being increased and diminished slowly and gradually by one cell at a time. (10) Before operating, the susceptibility of the patient to the current should be ascertained. (11) The problem is to absorb the stricture, not to cauterize, burn or destroy tissues. (12) *Weak currents* at long intervals should be used. (13) In most cases a current of six cells, or from two and a half to five milliamperes, will do the work. (14) The *séances* should last for from five to twenty minutes, and as a rule should be repeated about once a week. (15) The best position for the patient during the operation is that which is most comfortable to himself and to the operator. (16) *Anæsthetics* should be avoided, though in exceptional cases cocaine may be used. (17) Force should never be used. The bougie must be guided in the most gentle way, and the causation of hæmorrhage should be avoided. (18) During one *séance* two electrodes in succession should never be used. (19) All strictures are amenable to the treatment by electrolysis. (20) Pain should never be inflicted by the use of electrolysis. Therefore it should not be applied while the urethra is in an acute, or even sub-acute, inflammatory condition. (21) The electrodes should not be greased with substances which are non-conductors and would insulate. (22) For ordinary strictures the size of the bougie selected should be three numbers (French) larger than the stricture.

The advantages of electrolysis Dr. Newman summed up as follows: It is applicable to all strictures in any part of the urethra. It will pass and enlarge strictures in which other methods in the hands of skilful surgeons fail. It causes no pain or inconvenience. It is devoid of danger. It is not followed by hæmorrhage, fever, or any other unpleasant consequence. It relieves at once. The patient is not detained from attending to his daily business while under treatment. Finally, no relapse takes place.

From the foregoing description he said it would be seen that the present method of treatment by electrolysis differed in many points from that used between the years 1847 and 1870. Among the differences were the following: In the old method strong currents were employed which acted as a cautery and caused destruction of tissue and the formation of cicatrices. In Newman's method weak currents, which absorbed by a chemical decomposition, without giving rise to cauterization or cicatrices. In the old method short intervals between *séances* were employed, resulting in new inflammations; in Newman's method, long intervals, preventing inflammation and allowing restitution. Other points of difference were in the selection of the battery and the character of the electrodes used. A graphic description of the old method was given by Dittel in his work on strictures, in which he stated that he applied the positive pole (copper) to the stricture and the negative (zinc) externally on the limbs; and that he destroyed the stricture in one sitting by cauterization. It was no wonder, he thought, that such a method failed and was condemned. It was unfortunate, however, that even at the present day many were so impressed with the evils of the old method, that they did not take the trouble to consider the matter sufficiently to perceive the difference between this old method of cauterization and the new method of chemical absorption.

In reality, he said, there could be no valid objections

to the use of electrolysis in the treatment of stricture, and those which had been raised from time to time came either from those entirely ignorant of the fundamental laws of electricity or from those who had a personal interest or feeling in the matter. To the latter class belonged some surgeons of high standing who were wedded to the knife and had not fairly tested electrolysis. To those who objected to the method he could answer that he had used the endoscope in observing strictures for a period of over twenty years, that he had made experiments on dogs, and had proven his assertions by vivisections, by post-mortems, and by a large number of successful cases, many of which had been re-examined after from three to eleven years without a relapse, having been found. In addition, similar reports and observations had been made by many other surgeons.

When in 1887 a paper by Drs. Stevenson and Bruce Clarke was read before the Royal Medical and Chirurgical Society, in which the report of Dr. Newman's "One Hundred Cases without a Relapse" was referred to, one speaker observed that it was a very remarkable fact about Dr. Newman's cases that they were all successful. In reply to this, in a subsequent article published in the *British Medical Journal*, Dr. Stevenson said:

"That critic overlooks the fact that in the selection of these one hundred cases the first essential point was that they were discharged as cured, in order to see whether or not a relapse would take place. These hundred cases were naturally not consecutive cases, but collated from consecutive cases, for the purpose, and had to meet the following conditions: (1) The patients were to have been under treatment regularly and for a reasonable time. (2) They were to have been discharged as cured, or at least so improved that the patients were content with the result and did not wish any further treatment or improvement. (3) They were to be cases that were heard of afterwards by reliable information, mostly re-examined by the family physician or by Dr. Newman himself. Some of these patients came repeatedly for such re-examination. (4) That a reasonable time had been allowed between the discharge when cured, and the re-examination, which in these cases was respectively from three to eleven years. 'The proof of the relapse' was that the same sized sound was used in the re-examination which passed the last time at the close of the treatment. . . . All the facts have been distinctly stated, and those skeptical critics have overlooked the facts, and therefore have been unjust."

As to failure, Dr. Newman said that if the rules laid down for the treatment were carefully carried out there ought to be no failures, or at least they ought to be very rare. It was an undeniable fact, however, that failure had been reported even by medical men of good standing. In brief, the causes of failure depended on:

First, the operator; his incompetency, carelessness, want of patience, or non-management of the case, or to wrong diagnosis.

Second, faulty instruments.

Third, the patient himself, in not strictly following orders.

In regard to relapse, he said that one of the advantages of the operation was, that when a stricture was cured, no further relapse took place, and many reports by different operators had confirmed this fact.

There was, however, scarcely a rule without an exception, and scarcely an operation which might not fail by reason of some unforeseen concomitant circumstances. It was certainly safe to state that relapses will not occur when the patient has been discharged cured. In order that this might be claimed, it was necessary that the stricture or strictures should have been treated until the tissues were healthy, all the fibrinous, cartilaginous or cicatricial encroachments having been removed, and the size of the calibre was sufficiently enlarged. It was not necessary that the calibre should be enlarged abnormally, or even to its normal size, but only to such an extent that the patient could micturate comfortably and the bladder not be forced to extra exertions and painful contractions in order to relieve itself. This was generally accomplished after an electrode of No. 25 or 28, French scale, had passed easily. As many patients absented themselves after an improvement, when they felt comfortable but had not yet been cured, it was a natural consequence that the stricture should close up again; but in such cases as these, it was manifestly unfair to say that the failure was due to the method.

Mooted questions in the diagnosis and treatment of strictures, he went on to say, constituted an important factor in the discussion of this subject. On many points teachers and authorities disagreed, and consequently, arrived at widely divergent conclusions. Some had adopted certain measurements as a basis for the calculation of the size of a normal urethra. Others contended that erectile tissues could not be measured accurately, and that measurement of the same individual at different times would give different results. There was a diversity of opinion as to the normal size of a normal urethra, some placing it at a higher figure than others, and this diversity varied according to the form of instrument upon which the calculations were based. Opinions also differed greatly as to treatment, and the advocates of urethrotomy were generally bitterly opposed to electrolysis. In regard to the former, he quoted the following passage from a paper by Dr. John H. Girther, on "The Rational Treatment of Strictures of the Male Urethra."

"From the standpoint of antisepsis the operation of internal urethrotomy is a most glaring inconsistency, and a violation of the known laws of nature, as applied to this part of the organism. You cannot cut a stricture internally without at the same time cutting some of the sound tissue in its neighborhood. . . . Should the patient escape these dangers of infection, the worst is to follow, for after this traumatism, nature adopts her old method of preserving the integrity of the urethra, and deposits more lymph at the seat of the stricture, and in the adjoining healthy tissue, which in time organizes and contracts, and not the old stricture, but a tighter one, is formed, and the last state of that urethra is worse than the first."

After further discussing the question of what constitutes a cure, Dr. Newman said that the vital point was that the treatment must be called successful if the patient is well and content, whether his urethra is restored to the so-called normal calibre or not.

The Privy Council has approved of the resolution of the Royal College of Physicians declaring sulphuric ether to be a poison, and subject to the regulations dealing with the sale of poisons in Ireland.

AMERICAN PUBLIC HEALTH ASSOCIATION.<sup>1</sup>

SECOND DAY. — DECEMBER 17TH.

DURING the afternoon of the second day, Dr. WOOD, of North Carolina, introduced a resolution, providing that the Association should coöperate with the American Medical Association in preparing statistics and a history of vaccination, and in raising a fund for erecting a monument to Jenner, the discoverer of vaccination, in view of the approaching centennial of his discovery.

## EVENING SESSION.

Dr. RAYMOND, of Brooklyn, N. Y., presented two papers, which were illustrated by stereopticon views. The first paper was upon the

## TREATMENT OF SEWAGE BY PRECIPITATION AND SATURATION.

This was especially illustrated by a description of the process now employed for sewage disposal at Coney Island, and one or more other places. The precipitants employed were lime and chlorine. The daily amount treated was about 50,000 gallons, at a cost of \$6.50 or thirteen cents per 1,000 gallons. The claims which were urged for this system were: Concentration of the plant, absolute control of effluvia, economy of operation, convenient form of sludge-removal, and immunity from infection.

Dr. Raymond's second paper treated of the

## SANITARY IMPROVEMENT OF STAGNANT LAKES NEAR THE SEA-SHORE.

The ingenious plan adopted consisted in the letting in of sea-water through a trench or canal, the level of which was such that the waves of the sea at high tide each day broke over a weir, and passed into the lake or pond, converting it from a fresh water lake to a salt one. The lake was shallow, and of about eighty acres in area.

Dr. A. N. BELL, of New York, presented a paper intended to illustrate

## SOME OF THE SANITARY FEATURES OF CHARLESTON, ESPECIALLY ITS ARTESIAN WELLS AND ITS TIDAL DRAINS.

The water-supply of the city is taken from three artesian wells sunk to a depth of nearly 2,000 feet, and varying from two and one-half to five and one-half inches in diameter, and furnishing from 200,000 to 1,000,000 gallons of excellent water daily. The water is clear, sparkling, and has a temperature of about 100° F. as it comes from the wells. Its total solids are about 105 parts to 100,000.

Mr. L. J. BARBOT, the city engineer, described the sewerage system of the city, which consists of tidal drains. The early drains of the city were defective, and were but little better than elongated cesspools. Yellow fever was then very prevalent. The present sewers were devised in 1885 and 1886. They are furnished with tide-gates, by which they can be flushed out daily under a pressure of about four feet of water. The earthquake of 1886 caused serious disturbance to their level.

THIRD DAY. — DECEMBER 18TH.

## MORNING SESSION.

Dr. P. H. BRYCE, of Toronto, Secretary of the Provincial Board of Health, presented a paper on

<sup>1</sup> Continued from page 621 of the Journal.

## UNDERGROUND WATERS FOR PUBLIC PURPOSES,

in which the facts relative to the geological strata, in which underground water-supplies are usually sought, were stated with clearness; but when the author of the paper proceeded to elucidate his theories of capillary attraction as controlling the movements of underground waters, his statements were considerably less clear.

Dr. ABBOTT, of Massachusetts, presented to the Association some copies of a

## REPORT OF THE NEW ENGLAND KITCHEN,

an institution organized in Boston by Mrs. E. H. Richards and Mrs. M. H. Abel for the furnishing of wholesome and nutritious articles of food, at low prices, to the poor. It was stated that this was a practical outgrowth of the good accomplished by the Lomb prize essays.

Dr. WALCOTT, of Massachusetts, on behalf of the Committee on National Health Legislation, asked that a committee should be appointed to seek for legislation from the present Congress.

Dr. DURGIN, of Massachusetts, reported for the Committee on Emigrant Ships, that better regulations were desirable for the thorough sanitation of all ships carrying emigrant passengers. Certain rules were formulated, which should be everywhere adopted.

Dr. MONTIZAMBERT, of Quebec, presented a paper entitled

## THE VACCINAL PROTECTION OF PASSENGERS FROM CUBA.

He showed that small-pox, when occurring in America, is almost invariably introduced from foreign ports, and that there was great need of uniform requirements upon this point at all ports of arrival. Dr. Montizambert advocated vaccination of emigrants invariably on the first or second day after sailing, if done at all.

Several standing committees then reported. It was expected that a lively discussion would ensue upon the report upon the disposal of garbage, advocates of various methods having been present at previous meetings of the Association; but the report was very quietly disposed of without discussion.

Dr. HORLBECK, of Charleston, presented a paper on

## MARITIME SANITATION AT PORTS OF ARRIVAL.

Dr. Horlbeck gave much valuable historical information as to the epidemics of Charleston in its earlier years. He spoke especially of yellow fever as the chief disease to be guarded against at Southern ports. The quarantine station at Charleston was described, and the methods which were there adopted for the disinfection of ships and their cargoes, and clothing and baggage of passengers.

In the afternoon the Association were invited to a trip down the harbor to the quarantine station, which is located at Fort Johnson. The revenue steamer *Morrill* conveyed the members, and an excellent lunch was provided. The methods employed here for disinfection are quite similar to those adopted by Dr. Joseph Holt, at New Orleans, and consist in the application of steam and bichloride of mercury in solution. The steam is applied in a large, tight, iron cylindrical chamber.

The trip was rendered still more enjoyable in consequence of the opportunity which was offered for see-

ing all the points of interest which were concerned in the defense of Charleston Harbor in the Civil War.

#### EVENING SESSION.

DR. J. F. HIBBERD, of Indiana, presented a paper entitled the

#### HYGIENIC VALUE OF RATIONAL IRREGULARITIES IN HABITS OF LIVING.

He described the conditions of two young men living under different modes of life, hypothetical and exaggerated cases being purposely presented for the purpose of illustrating his subject. The formation of regular habits in eating, sleep and exercise was especially enjoined.

The next paper was entitled,

#### LAND MONOPOLY IN RELATION TO POPULATION HEALTH.

in which the author, DR. HOMAN, of St. Louis, endeavored to show that monopoly of land was inimical to public health. The sociological rather than the sanitary element predominated in the paper. The writer claimed that there should be no monopoly of land, unless monopoly of the air, water and sunlight were also permitted.

Four papers were read by title only, their subjects being as follows:

"Climate in Phthisis," by DR. GEDDINGS, of Aiken, S. C.; "House Drainage," by A. L. WEBSTER, C.E., of New York; "Trap Siphonage," by PROF. J. E. DENTON, Hoboken, N. J.; "Report from State Board of Health of South Carolina," by the President of the Board, DR. BRATTON.

#### FOURTH DAY.—DECEMBER 19TH.

DR. RAYCH, of Illinois, introduced a resolution that a committee should be appointed to inaugurate a sanitary exhibition at the exposition to be held at Chicago in 1893.

DR. PEUSKETT, of Tennessee, introduced a resolution that all maritime and quarantine authorities should exercise care to prevent the introduction of cholera into the United States.

A paper on "Leprosy, and its Management in Minnesota," by DR. CHARLES N. HUNTER, was read by title.

A resolution was also introduced that the Committee on Disinfection should append to their report, a statement of the practicable methods for disinfection in their charge.

It was voted that it was inexpedient to adopt the report of the Committee on the Disposal of Garbage, and to refer the subject to a new committee.

The following officers were then elected for the ensuing year:

PRESIDENT, DR. FREDERICK MONTIZAMBERT, of Quebec; FIRST VICE-PRESIDENT, DR. THOMAS F. WOOD, of Wilmette, N. C.; SECOND VICE-PRESIDENT, DR. HENRY B. HUBBARD, of Charleston, S. C.; TREASURER, DR. J. B. TOWNSEND, of Nashville, Tenn.; SECRETARY, DR. L. A. WELCH, of Concord, N. H.

It was voted to hold the next meeting in 1891, at Kansas City, Mo.

The Committee on National Legislation was informed by the address of Dr. EAKER, of Michigan.

## Recent Literature.

*The Throat and Nose, and Their Diseases.* By LENOX BROWNE, F.R.C.S., Senior Physician to the Central London Throat and Ear Hospital. New (third) and enlarged edition. In one imperial octavo volume of 734 pages, with 120 illustrations in color, and 235 engravings on wood. Cloth, \$6.50. Philadelphia: Lea Brothers & Co.

We are glad to see a new edition of this valuable work. The present edition differs chiefly from the earlier editions in the thorough manner with which intra-nasal and naso-pharyngeal diseases are treated. These subjects were somewhat hastily disposed of in the second edition, while in the volume before us they are discussed in a manner which their importance demanded. The illustrations of this work, from the author's pen-and-ink drawings, have long been celebrated.

The work is now complete; and we can cordially recommend it as a useful, practical, and safe guide, second to none.

*Household Hygiene.* By MARY TAYLOR BISSELL, M.D. New York: N. D. C. Hodges, Publisher. 1890.

The object of this little treatise is sufficiently expressed in its title. The advice and excellent information which it contains are tersely and intelligently expressed, and the book will be found to be a useful aid, not only to the householder, but to the house-builder, and to all persons interested in household economy. The following titles of chapters indicates the subjects which are treated: Site and Soil, Hygiene in Architecture, The City House and Plumbing, The Country House, Ventilation and Heating, Water-Supply, Kitchen and Table Hygiene, Sanitary Furniture, The Sick Room, Roof Gardens. A.

*The Philosophy of Tumor-Disease: A Research for Principles of its Treatment.* By C. PITFIELD MITCHELL, M.R.C.S., Eng. London: Williams & Norgate. 1890. pp. 263.

Any one who undertakes to write on a subject as comprehensive as the above, must have had large clinical and laboratory experience as well as a wonderfully analytical mind for the work of others.

As far as can be determined by the internal evidence the author has taken the first requisites at second-hand, and contented himself with attempting to establish his philosophy entirely from a study of books. But from this we fail to find wherein he has advanced our knowledge beyond previous writers. He has enriched medical language by the term "histogenic dissolution," to express the death of the cell in the production of its offspring, and this is used throughout as a name to conjure with.

The most valuable part of the book is the statistics of other authors, which are here brought together and might be useful for reference.

Suggestions of treatment are wisely left to the future.

—To sterilize catgut, Kammeyer has found that the best method is by dry heat. It can be subjected to a temperature of 110° C., without affecting its quality.

THE BOSTON

**Medical and Surgical Journal.**

THURSDAY, JANUARY 1, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

1888, 1889.**

**SUPPLEMENT AND REPORT OF THE MEDICAL OFFICERS.**

In addition to the usual official reports upon the subject of vaccination, this valuable volume contains twenty-eight special reports of medical officers upon scientific inquiries, all of which are of great interest to the medical profession.

It is worthy of comment that this board is required to investigate all alleged injuries due to vaccination; and although over 750,000 successful vaccinations were made in England during the year 1888, there were only ten representations alleging injury from vaccination. On inquiry, two of these were found to be measles and whooping-cough, concurrent with vaccination; two were skin eruptions; and the remainder were erysipelas or some similar disease.

The introduction to Dr. Barry's very complete report on the small-pox epidemic at Sheffield is reprinted in this volume, together with a report of a similar outbreak in the St. Joseph's Industrial School, at Manchester.

Abstracts of reports of medical inspections made at thirty-seven different places are also given. The greater part of these related to outbreaks of diphtheria. A portion of these are presented in full; and the following comments of Dr. Bruce Low upon that which prevailed will apply to many others, not only in England, but also upon this side of the Atlantic:

Not a few instances came to light in which parents, accompanied often by children, had visited at houses where diphtheria existed, for the purpose of condolence, gossip, or idle curiosity. And very commonly children regarded by their parents as practically well after diphtheria, were sent to school without trouble on the part of any one to obtain certification as to their freedom from infection. So, too, as regards what appear to have been mild cases of diphtheria, people have been content to take advice from "chemists," who have in turn given medicine for "colds" and the like, with the result that, in several instances, children having decided diphtheria have mingled with their fellows. Again, there is a custom at Enfield, among the working-classes, of assembling children of the family in the sick chamber to take their last leave of a relative, dead or dying

from infectious disease, and children have even been brought from other districts to take part in such formal leave-taking.

A report made by Dr. Blaxall, upon an epidemic of scarlet fever at Lower Brixham, contains the following suggestive statement relative to the spread of this disease through the public schools:

Within three days of the re-opening of the schools on September 3d, three children returned home from school ill with scarlatina. It follows that they had attended there while incubating the disease, and they were in all probability the means of introducing it into the schools. From this time scarlatina continued to spread amongst school-going children; and eighty-seven persons had to tell the tale of the first attacks in their families being in the persons of children who "returned from school ill" with the complaint.

Evidence went to show that the infection was kept up in the schools by children from infected families continuing to go to school up to the time of being themselves attacked, or, until the schools were closed; and again by children convalescing from the disease returning to school when in the desquamating stage. In this way the disease spread from infected to healthy children in the schools, and was carried by them to their respective homes, each newly infected child and family becoming in turn a fresh centre of infection to their immediate neighbors and others with whom they came in contact. There is no difficulty in accounting for the widespread nature of the epidemic, as well as for the scattered groups of dwellings that were invaded. I witnessed many examples of reckless exposure of infected persons. . . . Eye-witnesses spoke of children in the streets peeling the skin off their fingers to see who could get the largest flake. I heard also of the infected dead being kept in the houses from three to seven days awaiting burial, the children and neighbors in some instances going in to view the body and attending the funerals in large numbers. I met with repeated instances in which attacks followed within a few days of such exposure to infection.

A public ceremony took place on the 5th of November, on the occasion of laying a memorial stone on the spot where the Prince of Orange landed; and a large concourse of persons were thus brought together. Many persons stated that the first time of their children going out after their illness was to witness this ceremony; others, that their children were well when they went to see the stone laid; but, four or five days afterward, they were "down with the fever." There can be but little doubt that this assembling of infected and healthy persons was instrumental in spreading the disease.

Dr. Ballard's report upon the prevalence of pleuropneumonic fever in Middlesborough, is, like his previous work in other sanitary lines, a model report. He found himself confronted with peculiar questions of the causation of the disease and its relation to ordinary pneumonia. The outbreak at Middlesborough was found to be from four to six times more fatal than usual. Its principal fatality was among persons of fifteen years of age.

The peculiarities in this epidemic were its strong tendency to occur in groups of cases, with sequence of attacks among members of the same group, as is observed in most infectious diseases. The presence of local conditions of drain-filth appeared to favor its extension, and suspicion attached to food as having become contaminated with products of the disease.

The epidemic continued for six months or more. Pathological inquiries were instituted by Dr. Klein, who inoculated rodents with morbid material from the lungs and air-passages of patients. Dr. Klein also states that the disease spread in his laboratory by atmospheric spread of the infection. The bacilli described by Dr. Klein had differential characteristics of their

own, having no relation to other bacillary forms hitherto found in pneumonia.

Certain popular notions were prevalent at Middlesborough which attributed to the epidemic the characteristics of a *new* disease, having its origin in a particular kind of dust arising from a new process of pulverizing and sifting the slag which ensues in converting iron into steel. A majority of the practitioners of the district attributed it to the extraordinary character of the season, easterly winds, fogs and dampness being unusually prevalent. Others believed it to be directly infectious from one person to another. Popular prejudice at first forbade accurate pathological inquiry. Dr. Ballard examined a considerable number of specimens of bacon which had been made at Middlesborough from American salt-pork, and upon which suspicion rested. This bacon proved fatal to rodents which were fed upon it; and since the district in which this bacon was made and sold was coterminous with that of the epidemic, Dr. Ballard concludes that it may have been one of the factors in causing the outbreak. He also concluded that the disease was more or less communicable from the sick to the well. Serious faults in drainage arrangements were also deemed to constitute another important factor.

Dr. Klein's supplementary report adds much to the interest of the investigation. It treats of the microscopic anatomy of the diseased lung, and of the micro-organisms found therein, of experiments made to determine whether similar pneumonia could be induced in lower animals, and of certain examinations of the suspected bacon. From these inquiries Dr. Klein concluded, that, in the diseased lungs of persons who died in the Middlesborough epidemic, there appeared to be a definite bacillus, to which he gave the name of *bacillus pneumoniae*. Neither Friedländer's bacillus nor the diplococci of Fränkel and Weichselbaum was to be found in this lung tissue.

The "lung-juice" of this pneumonia inoculated into guinea-pigs and mice produced an acute disease, of which the chief and constant lesion was severe inflammation of the lungs; and further experiments in the same line of inquiry were confirmatory.

Dr. Klein's investigation relative to diphtheria is especially interesting. He gives an account of his inoculations of the false membrane of this disease into the bodies of animals. He found no definite result when rodents or birds were employed for experiment; but very notable results were secured when cats were made the subject of experiment. Upon inoculating these animals, he produced pathological conditions, differing somewhat from those of human diphtheria, yet bearing a general similarity to them. These conditions were found capable of reproduction by inoculation of the new discharges into other healthy cats. Dr. Klein proposes to continue this important branch of investigation.

Dr. Koch's relations seem to be scattered all over the United States.

# REPORT OF THE CHIEF OF THE BUREAU OF MEDICINE AND SURGERY TO THE SECRETARY OF THE NAVY.

THE report of the Surgeon-General of the Navy bears date of October 9, 1890, and contains the statistical report of the health of the navy for the year 1889, together with estimates for the fiscal year ending June, 1892, and with the present condition of the various naval medical establishments. In the tables which make up the body of the report proper, there is little to attract special attention this year; but the supplemental reports—the individual reports of various medical officers—contain a great variety of interesting material from various quarters of the globe, and illustrate the varied occupations of a naval medical officer.

The epidemic influenza finds mention in nearly every separate report, and is the subject of an article which condenses the information received from forty-one medical officers from the various stations occupied by the navy. Two medical officers were detailed to attend the annual meeting of the British Medical Association, at Birmingham, and the International Medical Congress at Berlin. Much of their reports is but a repetition of well-known events at these two meetings, but many original observations are given, especially in regard to matters of naval and military hygiene.

In his report on the International Congress, Medical Director Gilhou mentions the training of medical officers for military service in Germany, and is led to make the following application to our own country: "It is to be regretted that in our own country similar provision as is now general in all the leading nations of Europe is not made for the special training of the young medical officers of the army and navy. Now, the perhaps recently graduated young physician enters these services, and is at once assigned to independent duty of a technical character, where the responsibility is weighty and experience important, and where there may be no opportunity for him to obtain instruction or advice."

Interest in hygienic matters seems specially well developed in the navy. Whether it is the effect of the hygienic museum maintained under the auspices of the Naval Bureau of Medicine and Surgery, or whether that museum is the outgrowth of a pre-existing interest on the part of the medical officers, it is not necessary to inquire; but from the special report of Medical Director Wales through the reports from officers stationed at Sitka and on the African coast, we find the same general interest in the hygienic welfare of sailors on board ship or ashore, and of landsmen in their various relations.

As an extreme example of the careful supervision of the medical officer over the men under his charge, may be quoted a single recommendation from the officer in charge of the Naval Home for Aged Seamen. He says: "Some of these old men, . . . suffer both in health and in comfort from a cause for which at present there is no remedy. I refer to those who have lost teeth to such an extent as to render them unable

to masticate their food. . . . I think it highly desirable that a sum of money should be appropriated to defray the expense of providing false teeth and fitting them in all such cases at the Naval Home."

The reports from the new vessels of the Squadron of Evolution; from the vessels that were wrecked in the gale at Samoa; from the *Pensacola*, that carried the party of observation to Africa to observe the total eclipse of the sun; from the officer detailed to the United States Coast Survey Steamer *Bache*; from the officer stationed at Pago Pago; from the *Pinta* at Sitka, Alaska, show a variety in the character of the service, and an adaptability to all sorts of conditions, that cannot fail to add greatly to the respect which our brethren of the navy everywhere receive.

### A KNOTTY QUESTION OF ETHICS.

THE versatile and ingenious Gaul has invented a new problem of medical ethics, with which the already perplexed conscience of the practitioner of medicine is to be still further charged. The question is briefly this: A medical chemist is requested to make a urinary analysis and examination in the case of a patient whose name is given, we will say, as "Mlle. X." In the sediment he finds, among other abnormal constituents, certain specimens of the spermatozoon. Shall he include this item in his formal report to be sent, we will suppose, to the young woman's anxious parents? Or shall he dissemble, taking the ground that the element in question is not an evidence of any depraved function, except indeed of a moral nature; that the parents' inquiry had reference to physical disease and that the revelation in question was really only an accidental finding on his part, and was therefore to be kept quiet like any other fact of one's surroundings which one happens to see, but is not meant to see, as for instance, the summer flirtation behind a boulder, that one blunders upon unawares?

The French contemporary which proposes this problem suggests as a solution the following: That when the specimen of urine is sent the expert by the patient's physician, the report should include everything, even to a stray and misplaced spermatozoon, on the ground that the doctor is entitled to know *all* that is to be known; but that when the report is to be made directly to the patient or her family, such a discovery should be suppressed as irrelevant to the case.

One difficulty with this disposition of the matter, that must be met by the prudent examiner who is anxious not to compromise the domestic relations of his patrons, is that, before deciding on a modification of his verdict, he must ascertain whether the patient is married or single, and if the former, whether or not the husband is "in residence." But sometimes no name at all may be given. Even the sex of the patient may be concealed (unless the examiner is able by his own microscopic researches to settle that point), and he will be kept constantly anxious lest he have

committed an imprudence. In view of this uncertainty, it seems evident that the discreet examiner has but one course open to him, namely, uniformly to suppress the fact of the discovery of the spermatozoon in all cases!

### MEDICAL NOTES.

— It is announced that a spurious imitation of Koch's fluid is being manufactured in Berlin, and a number of cases have been reported in which foreign medical men have been deceived into purchasing the bogus preparation.

— Pisa has been heavily visited by an epidemic of typhoid fever. On December 3d, eighty cases were reported. The disease assumes a peculiarly malignant form, running rapidly into infectious pneumonia.

— The epidemic of small-pox in Madrid showed an increase during the first days of December. In November it attacked 2,100 persons, of whom 750 died. The epidemic at Lisbon shows no sign of abatement, and loud complaint is made by the medical press of the insufficient hospital accommodation provided for the sufferers. The Portuguese public are gradually waking up to the importance of vaccination and revaccination.

— The movement for a free hospital in Lowell reached the stage of organization during the week.

— As the result of a public meeting held last summer in Nantucket, to see if a system of sewerage could be introduced, Dr. H. J. Barnes has submitted an exhaustive opinion, in which the different methods of dealing with sewage are discussed, with special attention to the soil treatment as applicable to the needs of the town.

— The corner-stone of the Henry W. Grady Hospital, at Atlanta, Ga., was laid with fitting ceremonies, on the anniversary of Mr. Grady's death.

— There are said to be nine hundred men now employed in Washington in filing, searching, indexing, repairing, and making reports from the medical, surgical, and service records of the Union armies. The principal work of the men thus employed is to furnish information to the Pension Office concerning the official records of 500,000 applicants for pension.

— The fatal injury of a New York lady, who fell upon the sidewalk in that city, the other day, and drove her hat pin into her brain, is being used to point the moral that the hat pin is a dangerous article of women's wearing apparel, and ought to give way to the old-fashioned elastic or bonnet strings.

— A society has been organized in New York to keep sane people out of asylums, and to get sane people unjustly committed, out. This society, which is known as the Anti-Kidnapping League and Lunacy Reform Union, declares that in the last five years, and in New York city alone, more than one hundred persons have been found by the courts to be unlawfully confined in asylums.

—The Russian Government has appointed a committee, consisting of Professor Tarnovski and other syphilologists, to adjudicate the award offered for the best popular work on the dangers of syphilis, and on prophylactic measures for preventing its spreading.

—A method of keeping soft rubber tubes, cloth, stoppers and other articles soft and pliable, according to Gawalowski, consists in keeping them in a ten per cent. watery or alcoholic solution of creolin. Before using they are simply taken out and washed in water, and after being used are put back into the creolin solution.

—Six or seven years ago two women were murdered at Lyons, one while asleep, and the other after a desperate struggle with the assassin, who was never discovered. As a precautionary measure, the expert, M. Ferrand, injected the blood-vessels previously to interment with an antiseptic solution. Recently these corpses were exhumed, and in one the expression noticed immediately after the commission of the crime was remarkably preserved. Both the bodies were in an almost perfect state of preservation.

—A short time ago Professor Albert, in Vienna, said in his class-room that he had just received an anonymous letter, in which the writer censured him for amputating the arm of a woman who was suffering from advanced arthritic tuberculosis, when Koch's recent discovery was within his reach. Professor Albert said that this letter had outrun our present knowledge. The whole of our present knowledge is hazy and indefinite, and beyond the hypothetical expressions of Koch himself, we are not justified to proceed. Koch has expressly said that "Phthisis in its incipient stage he can cure, but for advanced conditions he had as yet no remedy." He distinctly says that other factors, as situation, abode, nourishing diet, and the use of medicines must not be neglected. Concerning this case of arthritic tuberculosis charged against Albert, he referred to Koch's publications on the subject, in which he is very reserved. He says healing in the early stages is very slow, and that the life of the patient can only be preserved by amputation, even in spite of his small tube of golden fluid.

—An entirely new departure in medical legislation is embodied in a bill now before the legislature of New South Wales. Every person practising medicine, surgery or midwifery for gain, shall have his name placed conspicuously upon the house or premises in which he carries on his calling. Provided that any such person so practising who is not registered as a practitioner, shall notify the same beneath his name in the manner to be provided by regulations; and any person who shall advertise as treating disease, injury, or ailment, shall state his Christian and surname in full in the advertisement, also shall place them upon any house or premises to which such advertisement refers, and if not a practitioner, shall also add the words "not registered under the Medical Act, 1890," in such manner as to be provided by regulations.

## Miscellany.

### ALTERABILITY OF DIURETIN.

LAMBERT<sup>1</sup> has found that this substance is decomposed by all acids, even carbonic acid. Exposed to the air it becomes partially insoluble, making it necessary to treat it with caustic soda. Even in solutions, carbonic acid acts upon diuretin; and the mixtures become cloudy on account of the precipitation of theobromine. Not only weak acids, but such salts as the biborates, bicarbonates and dimetallic phosphates decompose diuretin; hence, we cannot use it with fruit syrups, or with soda carbonate. There is no advantage in giving theobromine transformed into diuretin, since, on reaching the stomach, it is decomposed by the gastric juice. It would be preferable to give theobromine in cachets, or by enema.

### BERI-BERI IN JAPAN.

DR. TAKAKI,<sup>2</sup> of the Japanese navy, is of the opinion that the small number of cases of kak'ke or beri-beri during the present year is entirely due to the fact that the price of rice has been so high that the lower classes have been obliged to use more wheat and beans. He is now investigating the relation between the number of kak'ke patients and the quality of food in different parts of the empire. In view of the recent reports of cases of beri-beri on fishing vessels from the banks of Newfoundland, Dr. Takaki's results will be of interest to us. Some years ago, through his influence, the Japanese navy entirely changed the kind of food supplied to the ships, much increasing the nitrogenous and fatty material. The result was remarkable. Whereas before, the ratio of cases of the disease to the total number of men employed had been from twenty-five to forty per cent. each year, within two years it had fallen to less than one per cent., and now practically never occurs.

### PRECOCIOUS MATERNITY.

DR. A. T. EVANS,<sup>3</sup> reports that he was called to a negro girl, aged eleven years and eight months, who had been in labor twenty-four hours. She was delivered of a healthy female child, and at the time of the report both mother and child were doing well.

At a recent meeting of the Calcutta Medical Society, Dr. Youbert<sup>4</sup> related the case of a Bengali girl, aged thirteen, who had been delivered in the Eden Hospital. She was ill-developed, had no hair on the pubes, though the breasts were enlarged, owing to her condition. She had been in labor for thirty hours. The mucous membrane of the passages was of an ashy color, and the labia oedematous. She was very prostrate, and the head lay above the pelvis. The forceps was applied, but in extracting the child the perineum gave way, and was badly lacerated into the rectum. It was sutured, but the parts sloughed. The child still-born. The distance between the anterior superior spinous processes of the ilium was a little under seven and a

half inches, against nine and nine and a half in well-formed women. The mother said that she had menstruated a year before, and that she had lived with her husband for six months before she became pregnant.

### CHRONIC CONSTIPATION.

At the meeting of the Berlin Medical Society, Herr Flatau<sup>1</sup> introduced a new method of treating chronic constipation due to torpor of the colon. This consists in applying about three grammes of boric acid. In those cases in which the lower edge of the rectum protrudes through the anus and when this remains visible after powerful contractions of the levator ani and sphincters, the quantity of boric acid mentioned is either to be dusted on or rubbed on the mucous membrane in sight. In cases in which the mucous membrane is not visible, it must be insufflated. It is important that the medical attendant should carry out the procedure himself, at any rate at the commencement. The patient should then keep quiet for a time. In from an hour to three hours, peristaltic action will be observed in the colon. He has never seen a failure from this method of treatment, nor had he seen a case where the patient got so accustomed to it that it ceased to be effective. On the contrary, if carried out systematically daily, permanent improvement in time takes place, and normal peristalsis is returned to. He had tried a number of other substances but none had the same useful effect.

### LIABILITIES FOR RAILROAD ACCIDENTS.

In spite of the fact that railroad companies often suffer unjustly by sympathetic juries, there are two classes of cases in which a person injured in a railroad accident appears at a disadvantage in a court of law. First, employes cannot hold the company responsible for the carelessness of fellow employes, and second, some railroads, by employing surgeons whom they can command, to the exclusion of others, leave the unsuspecting patient, when the case comes into court, with nothing but damaging *ex-parte* medical evidence. A law passed by the last legislature of Ohio remedies the first defect and strikes a blow at the second. The bill, which makes co-employes responsible for accidents to each other, is discussed in a recent paper by Dr. R. A. Vance of Cleveland.

Under the new law an employe has just as much right as any other person to sue and recover. The legislators bumbled wiser than they knew, they not only passed a law giving employes justice but they struck a blow at a most pernicious system, that of employing surgeons for *ex-parte* testimony. While the surgeons did not make large fees in taking care of the wounded, it was not unusual for them to make large amounts of money in compromising damage suits. The speaker said that the new law had put such employes upon exactly the same basis as other employes. When a suit for malpractice is brought and the question at issue is whether the surgeon shall pay damages from his own pocket, the law requires that the surgeon shall exercise only ordinary skill and be possessed of ordinary ability. If ordinary skill has been exercised with ordinary care, the

plaintiff cannot recover. If, however, an employe be injured under the new law and his injuries be attended to by a surgeon who is a co-employe, and a suit for malpractice result, it will not do for a company to set up the defense that ordinary skill has been exercised. The jury will feel that a company ought to employ the best talent and not be content with ordinary talent.

### DETECTION OF BILIARY PIGMENTS IN URINE.<sup>2</sup>

To four or five cubic centimetres of slightly warmed urine five to ten drops tincture of iodine are added, agitating after the addition of each drop; in the presence of biliary pigments a pretty olive-green coloration is produced. Excess of tincture of iodine will produce a dirty brown-red color; normal urine at first decolorizes the iodine solution, then gives a red coloration, and on addition of an excess of iodine a dirty brown-red color.

### THE PILGRIMAGE TO MECCA.

As is well known, every Mohammedan must at least once in his life-time make a pilgrimage to Mecca.<sup>2</sup> The rich Mohammedans go yearly. There are four months of the year during which the journeys are made. Beginning at the West, the Mohammedans come from the west coast of Africa as far south as Senegal, arriving by caravan, and taking vessels on the Algerian coast, or they may go by caravan as far as Alexandria. From the far East, they come from the Strait Settlements Singapore, Java, Sumatra, Ceylon, and the coast of India.

Those who die *en route* to Mecca are assured of eternal salvation, and this accounts for their utter indifference to sickness and death. This year 43,000 pilgrims arrived at Jeddah by sea, of which number only 28,000 returned. Fifteen thousand were therefore left on the plains or along the route of travel. The average number of deaths per day was 600, and it is well known that a large proportion of the mortality was caused by cholera. The vessels that convey these pilgrims are the vessels of all the civilized nations, and the manner in which they are allowed to be over-crowded is disgraceful. The condition of the pilgrims is filthy and pitiable. They invariably carry their own provisions, the ship furnishing none, and many suffer from want of proper food. They are packed together "as close as sardines," not only "between decks," but on the upper deck, where they have scarcely room to move. The most serious feature of this transportation, is the fact that the latrines for their use are built out over the vessel's sides forward, and the ship's sides become filthy in the extreme, and cannot be, or at least are not, cleaned *en route*. As cholera generally appears among the pilgrims, the danger is obvious. The ship's crew complain of the risk to themselves. For days after the pilgrims have disembarked, and even after fumigation and repeated washing out of the bilge, a strong stench clings to the vessel. This same vessel may immediately go to a healthy port and secure cargo with a clean bill of health, and sail for any port in the United States. Ordinarily a vessel's bow and sides will receive a thorough washing, but at times a steamer

will encounter smooth seas throughout the voyage, nor is it beyond reason to suggest that in isolated portions, in seams, on hawesers, tackle, etc., choleraic dejecta may remain.

#### THE TREATMENT OF SURGICAL TUBERCULOSIS BY KOCH'S METHOD.

As the result of his experience in the use of Koch's fluid in cases of surgical tuberculosis, Professor Levy draws the following conclusions: Some patients suffering from tuberculosis of joints were able to walk much more easily after the injection than before. Some of them have been under treatment for two months. Two children with tuberculosis of the knee and a man of forty years of age with disease of the hand have been discharged cured. In these cases injection of large doses failed to cause any reaction. A boy of thirteen, with a fistula on the back of the hand, due to tuberculous osteitis of the metacarpal bones, is apparently entirely cured. When first treated the fistula and neighboring parts became enormously swollen after each injection, now there is no reaction, either local or general.

It is not necessary to recite other cases. It will be necessary to collect a very large number of clinical histories before the exact value of the method is determined. The action of the fluid on lupus is especially noteworthy. Enough has been seen to show us that we have good reason to hope that a cure for tuberculosis is a possibility. The certainty of diagnosis by this means seems to be established, since it is not necessary now to demonstrate the presence of the tubercle bacillus, but we are justified in basing our diagnosis on what might be called an exploratory injection. If tubercular disease exists a typical tumefaction occurs, with concomitant pain, which gradually disappears. It is true that, for accurate diagnosis, the tumefaction and the pain should increase, attain their height and diminish in a typical manner; that is, the increase in swelling and pain should go hand-in-hand with elevation of temperature, and with the fall of body-heat they should subside.

In considering the treatment of surgical tuberculosis by this new method, we should compare the results with those obtained by the old method of treatment. Incisions into tubercular tissue were made with a view of removing the diseased tissue only where the extent of the disease was limited; in more extensive trouble surgical interference was undertaken only with a view of prolonging life by limiting the suppuration and other exhausting conditions.

With the method of Koch at our disposal the surgeon must look at certain conditions in an entirely new light. To begin with we must refrain from all surgical interference which is not absolutely necessary, for it is our duty to first cure if possible the tubercular infection, hoping that when once cured it will not return. During the treatment Levy used massage, and encouraged the use of the limb as far as possible, for there is, he thinks, no longer any fear of tubercle bacilli being forced into the circulation; in fact, they can be better combated in healthy than in diseased tissue.

When the disease has been cured, the duty of the surgeon ends. It is unnecessary to find the results of the previous treatment, provided it is necessary.

I should we may say that with much less surgi-

cal interference we may obtain very much better results, and may go to work with much more confidence since the principal object, the complete cure of our patient, is much nearer our grasp.

#### OBITUARY. ALFRED F. HOLT, M.D., M.M.S.S.

DR. ALFRED F. HOLT, Surgeon-General of Massachusetts, died of Bright's disease, on December 28th, in Martin, Fla., where he had been for about two weeks on account of his health. Dr. Holt was born in Lyndeborough, N. H., in 1838. He was brought up on a farm, and obtained his early education in the public schools of his native town and at Mount Vernon Academy. He began in 1857 to attend lectures at the Harvard Medical School, and in the spring of 1860 completed his studies at the University of Vermont, from which institution he graduated. He began the practice of medicine, in 1860, in Cambridge, but with the breaking out of the war in 1861 he joined a company of volunteers, which was afterwards attached to the Third Regiment, M. V. M. He served a few days as a private in the ranks, and was then promoted to be hospital steward, in which capacity he served three months. In November he joined the medical department at Camp Chase, Lowell, working in the hospital until December 6th, when he was appointed Assistant Surgeon of the Thirtieth Massachusetts Volunteers, going with the regiment to the Department of the Gulf. He served here until December, 1862, when he was promoted to be surgeon of the First Texas Cavalry. Receiving, in 1863, a commission as senior major of the same regiment, he left the medical department, and in 1864 was made lieutenant-colonel, and served in that position until October, 1865, when the regiment was mustered out of service. He returned to Cambridge in 1866, and again began practice. In July, 1879, he was appointed medical examiner, and in January, 1884, was commissioned surgeon-general, in both of which capacities he was serving at the time of his death.

For the duties of surgeon-general he was eminently fitted. He took a deep interest in the old soldiers, whose claims for assistance were submitted to his judgment. The worthy were always sure of his sympathy and assistance, but he valued too highly the reputation of a veteran not to feel indignation against any who were willing to make their military service a basis for begging. The medical department of the militia owes much of its efficiency and high standing to his efforts. The ambulance corps of the State have developed since his incumbency of the surgeon-general's office, and were a source of interest and care to him.

During the present administration he has held the post of pension-examiner. He was a member of the American Association for the Advancement of Science, Loyal Legion and Grand Army of the Republic. He was an acknowledged authority in forensic medicine.

In regard to his military services, Dr. Holt was accustomed to show that characteristic common to so many of our returned volunteers. It was not easy to get him to tell anything about his personal experience. The existence of a general order commending him for "unexcelled courage in taking on his back, under a hot fire, the wounded soldiers as they fell," was probably unknown to most of those who knew him best.

He had been a widower for twenty years, and leaves no children.

#### Correspondence.

##### KOCH'S TREATMENT OF TUBERCULOSIS.

BOSTON, JAMAICA PLAIN, December 30, 1890.

MR. EDITOR:—Having arrived at home yesterday from Berlin, where I passed about three weeks studying Koch's treatment of tuberculosis, I am glad to respond to your re-

quest for a brief statement of the results of my experience.

There is absolutely no question that Koch's fluid is one of the most powerful things known. In cases where reaction is obtained easily it is brought about with a milligramme dose. The temperature of a patient, normal at time of injection, will rise during six to ten hours following to 103° to 105° F.; respiration is markedly increased; much perspiration, pulse rapid. Sometimes there is icterus—the condition seems quite distinctly septicæmic. The local reaction is nothing at all. In pulmonary tuberculosis we cannot see its effect, of course. In the case of lupus and joint tuberculosis, at the particular spot where the pathological process is going on, we observe swelling—appearing to undergo very great change; and it is there that the reaction shows itself particularly, in addition to the systemic symptoms. In a fresh case this lasts overnight. The injection being made at 8 o'clock A. M., in the middle of the afternoon the symptoms will be fully marked in many cases; and by the next morning the average case will be as before the injection. In some cases the effects last longer, and it would seem that some individuals are more susceptible than others, as is the case with other medicaments.

The most important advantage which I obtained from this journey was the opportunity given of watching the cases from the beginning of the treatment. One unaccustomed to the administration of the fluid and the symptoms it produces, will, to say the least, be very much alarmed at effects produced in the full course of the reaction, and it is difficult to realize that some serious injury has not been done to the patient.

As I stated in my cablegram (JOURNAL, December 11th, p. 575), the cases of lupus and external tuberculosis are the only ones from which we can gather our knowledge at present. In pulmonary tuberculosis the reaction is concealed, and we can only judge of the process going on in the lungs under this treatment, by what we observe externally.

Regarding the usefulness of Koch's fluid: the cases were not actually complete when I left for Boston, but there were two cases of lupus of the face, which were practically well, where a series of injections had been going on for about six weeks, some six to ten injections having been given during that time. The lesions at entrance had extended over the whole lower portion of the face from the bridge of the nose to the base of the neck, involving the mucous membrane of the mouth, with destruction of the nasal cartilages; in one case the vocal cords were partly destroyed. At the time of entrance the process was sluggish, comparatively little discharge, and very gradual destruction of tissue—evidences of a slow chronic process of long standing. In these cases the tremendous rise of temperature following each injection was very striking. Extreme activity was set up in the skin and mucous membrane of the diseased parts. After the injection the lesions were much swollen, with great discharge from the skin and mucous membrane; then the symptoms would abate until the injection was repeated, the reaction, increase in temperature, and physical symptoms gradually diminishing. In the course of a month it was possible to see, cycles of cicatricial tissue forming, and then the discharge following the injections very much lessened. In one of the cases there was apparently healthy skin forming in spots all over the face, where before there was a granulating, ulcerating surface. These cases I saw.

Of the pulmonary cases not quite so much can be said. The reaction following injection was as great as in cases of external tuberculosis. The pulmonary symptoms, as shown by cough and quickened respiration, were increased, but no especial change in the physical signs were evident, excepting in a comparatively small number of cases. Just before I left, the statement was made to me that, taking some forty or fifty pulmonary cases in one of the clinics, for the first five weeks they had shown a gradual improvement, but a few days before there had been a change in the contrary direction. The significance of this change, it is, of course, impossible to estimate; but, in

general, considering the results of pulmonary cases so far, I am led to believe and insist upon the apparent fact that the pulmonary cases suitable for treatment with our present knowledge of this fluid, are pre-eminently those in the early stages.

In those cases where the larynx has been attacked, the swelling following the injection is probably as much as in skin tuberculosis of other parts of the body, and the danger of producing any swelling of the larynx in such treatment is as great a danger as producing an acute attack of croup. So, in these cases, progress must be made slowly and carefully, and the necessity for performing tracheotomy must be borne in mind.

Kohler having charge of the surgical cases, with Westphal his assistant, and Leyden having charge of the medical cases, and Klemperer, his assistant, placed charts at my disposal, which I have photographed of; and I shall show them as soon as I can get them into good condition.

Very truly yours,

HAROLD C. ERNST, M.D.

## THE FIRST ADMINISTRATION OF ETHER.

FITCHBURG, MASS., December 30, 1890.

MR. EDITOR:—By the obituary notices of the late Dr. Henry J. Bigelow, I am reminded of an incident, not published, so far as I know, in the record of the first public surgical operation, under the influence of sulphuric ether, by Dr. John C. Warren, October 16, 1846.

The ether was administered by Dr. W. T. G. Morton, a dentist of Boston, who had explained the operation of his discovery to Dr. Warren. The patient was a woman of forty-five to fifty who had a malignant tumor in the left superior maxilla. I was present, and sat where I could see the minutest details of events.

The ether was administered from a bulbous glass instrument, in which was a sponge containing the ether. There were two valves. One of them was intended to admit fresh air; the other was supposed to allow the escape of expired air. As the operation proceeded, the patient grew livid; there was cyanosis; respiration was shallow and feeble; death seemed imminent.

The operation being completed, under the influence of cold water and fresh air, the patient revived, having suffered nothing from the hands of the surgeon. A careful examination of the instruments revealed the fact that the valve for the admission of fresh air had ceased to act, and the patient had been asphyxiated.

Very truly yours,

GEORGE JEWETT, M.D.

## METEOROLOGICAL RECORD,

For the week ending Dec. 20, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Barometer	Thermometer.		Relative humidity.		Direction of wind.		Velocity of wind.		Weather.		Rainfall in inches.

Deaths reported 2,894; under five years of age 887; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fever) 301, acute lung diseases 188, consumption 317, diphtheria and croup 169, typhoid fever 56, scarlet fever 17, diarrhoeal diseases 28, measles 28, whooping-cough 19, cerebro-spinal meningitis 11, malarial fever 11, erysipelas 6, puerperal fever 6.

From diarrhoeal diseases New York 11, St. Louis 8, Chicago and Lowell 1 each, Cincinnati 3, Boston and Nashville 2 each, Philadelphia, Brooklyn, Cambridge and Salem 1 each. From measles New York 15, Chicago 8, Brooklyn 3, Washington and Nashville 1 each. From whooping-cough Chicago 6, New York 5, Philadelphia and Brooklyn 1 each. From cerebro-spinal meningitis Chicago 4, Brooklyn and Washington 2 each, Philadelphia and Lawrence 1 each. From malarial fever Brooklyn 6, New York 5, Charleston 2. From erysipelas Chicago and Boston 2 each, New York 1 and Brooklyn 1 each. From puerperal fever Chicago 3, Boston, Nashville and Quincy 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 3,715,559, for the week ending December 6th, the death-rate was 21.5. Deaths reported 3,999; acute diseases of the respiratory organs (London) 141, measles 202, whooping-cough 69, scarlet fever 64, diphtheria 63, fever 19, diarrhoea 426.

The death-rate, based on 12.7 in Hull to 36.2 in Preston, Birmingham 21.0, Huddersfield 21.0, Leeds 21.6, Leicester 19.9, Liverpool 24.7, London 20.1, Manchester 28.2, Nottingham 16.2, Portsmouth 20.5, Sheffield 24.7, Wolverhampton 18.8.

In Edinburgh 18.5, Glasgow 20.4, Dublin 29.7.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 20, 1890, TO DECEMBER 26, 1890.

By direction of the Secretary of War, Captain EDWARD J. GINSBURGH, assistant surgeon, on leave of absence, will report in person, at the city, to the commanding officer, Fort Meade, and, if necessary, in conformity with the Seventeenth Infantry, in the field, report, by letter, to the commanding general, Department of Defense, S. O. 298, Par. 9, A. G. O., Washington, D. C., December 26, 1890.

By direction of the Secretary of War, leave of absence for six months, on account of disability from duty, with permission to

leave the Department of Texas, is granted Captain JOHN J. COCHRAN, assistant surgeon. S. O. 298, Par. 2, A. G. O., December 22, 1890.

By direction of the Secretary of War, the leave of absence granted First Lieutenant FREEMAN D. WALKER, assistant surgeon, in Special Orders 85, Department Platte, November 11, 1890, is extended one month. S. O. 298, Par. 9, A. G. O., December 22, 1890.

## OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING DECEMBER 20, 1890.

WYMAN, WALTER, surgeon. Granted leave of absence for twenty days, to attend meeting of American Public Health Association December 12, 1890. December 11, 1890.

LONG, W. H., surgeon. Granted leave of absence for seven days. December 20, 1890.

MURRAY, R. D., surgeon. Granted leave of absence for thirty days. December 20, 1890.

IRWIN, FAIRFAX, surgeon. Detailed for special temporary duty at Marine-Hospital Bureau. December 10, 1890.

CARTER, H. R., passed assistant surgeon. To attend meeting of American Public Health Association. December 11, 1890.

WASDIN, EUGENE, passed assistant surgeon. To attend meeting of American Public Health Association. December 11, 1890.

KINVOEN, J. J., passed assistant surgeon. Granted leave of absence for thirty days, with permission to go abroad. December 11, 1890.

GIDDINGS, H. D., assistant surgeon. Upon expiration of leave to proceed to New York, N. Y., for temporary duty. December 18, 1890.

## KOCH'S TREATMENT OF TUBERCULOSIS.

Dr. Harold C. Ernst will give a short account of work upon Tuberculosis as at present conducted in Berlin, at the operating theatre of the Massachusetts General Hospital, Thursday, January 8th, at 8 P. M. The medical profession are invited to be present.

## SOCIETY NOTICES.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a meeting of this Section, at 19 Boylston Place, on Wednesday evening, January 7th, at 8 o'clock.

Communications: Dr. F. B. Harrington, "Rheumatic Flat-Foot"; Dr. E. H. Bradford, "The Treatment of Spina Bifida"; Dr. J. W. Elliot, "Nephrectomy for Hydronephrosis."

GEORGE H. MONKS, M.D., Secretary.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held, at 19 Boylston Place, on Monday evening, January 5, at 8 o'clock.

Readers: Dr. C. P. Strong, "Amniorrhoea Considered as a Functional Disorder"; Dr. F. H. Davenport, "Some Forms of Amniorrhoea and the Treatment."

T. F. SHERMAN, M.D., Secretary.

## OBITUARY. PROFESSOR FRIEDRICH SALZER.

Professor Friedrich Salzer, Chief of the Second Chirurgico-Gynaecological Section of the Allgemeine Krankenhaus in Vienna, died suddenly on November 30th, at the age of sixty-three. He was born in 1827, studied medicine at Vienna, where he was one of Schnil's assistants. In 1870, he was appointed Professor Extraordinary of Surgery. In him consummate surgical skill was associated with remarkable good luck in the results of his operations, but he contributed comparatively little to surgical literature. For the last nine years he suffered frequent pain from an affection of the nerves, but recently has been so much better that he had begun to hope for ultimate recovery.

## DEATHS.

In Waltham, Mass., December 28, 1890, Theron Temple, M.D., M.M.S.S., aged fifty-seven years.

Robert P. Gibson, M.D., of New York City, died December 27th, aged seventy-one.

James Harvey, M.D., formerly of Detroit, Mich., died December 19th.

Anthony Hagarty Corley, M.D., F.R.C.S., Professor of Surgery in the Royal College of Surgeons, died in Dublin, December 1st, aged fifty.

Professor Ernst Adolf Coccius, since 1857 Professor of Ophthalmology in the University of Leipzig, died recently at the age of sixty-five.

## Original Articles.

### PROVISION FOR THE CARE OF ADULT PAUPER EPILEPTICS IN MASSACHUSETTS.<sup>1</sup>

BY WM. N. BULLARD, M.D., BOSTON.

OUT of the many thousand pauper patients who, in the course of a year, seek treatment in our large hospitals and charitable medical institutions, there is no class for whose proper care and protection the means at our disposal are so utterly inadequate as for adult pauper epileptics. Beyond certain mild palliative therapeutic measures, we have no resource until the patients become fit subjects to be legally committed to institutions for the insane. The only exceptions are those cases where surgical interference is deemed desirable. In the whole range of medical practice in Massachusetts, there is no class of patients whose interests have been so thoroughly neglected.

The cause of this is not wholly clear. It has, no doubt, been due in part to the inherent difficulties in making such provision, and largely, also, to the ignorance and indifference of the public at large, caused by the want of energy of the medical profession in drawing attention in this direction. There seems to be at present in the minds of many persons, a hazy notion in regard to epileptics, that when the attacks are frequent and severe, the patients are insane, and when they are not so obtrusive, they should be treated as if well, look after themselves, be cared for by their friends, or be sent to almshouses, or other regular pauper institutions. It is scarcely necessary for me to state that these views are wholly false. There is probably no considerable class of the physically or mentally afflicted, which contains so large a proportion of persons demanding our deepest pity, or which entails so large an amount of suffering for each person, as that comprising the chronic epileptics. They are, as a whole, much worse off than the chronic insane, worse off even than the acute insane, for the condition of the latter is but temporary. The chronic epileptic is, however, in a condition which may be described as one of recurrent insanity. The attacks are not so suffering in themselves. During them, the patient is unconscious, but the condition preceding is often one of much mental pain and it is the constant dread of the attack, always impending, occurring at any time without notice, which causes the greatest strain. There is also, the mental condition of depression, and of uncontrollable fear and terror produced by the disease itself which adds to its horrors. These facts are well known to the medical profession, and I should hardly have deemed it worth while to have mentioned them here, were it not that we have too long been inclined to treat them with apathy and indifference. This condition of suffering seems to have been too often passed over as one of those things which, alas, exist, and which we must admit as belonging to the inevitable, but which, with our imperfect means, it is useless to attempt to combat or control.

That, possibly, at one time, with the means then at our command, this view may have had a real foundation, I am quite willing to admit, but I deny that at the present time this view is tenable, or in any way justifiable. It is neither true in fact, nor is it just to

the sufferers, that it should longer be held. We can, if the proper means be provided us, do much to alleviate the sufferings of these patients, and if, in many cases, we cannot wholly cure them, we can render their life infinitely more comfortable and more bearable. To aid in doing this, seems to me to be the duty of all who know and pity these unfortunate.

Thus far I have spoken only from the point of view of the welfare of the patients and their freedom from suffering, but this subject must also be considered as regards the welfare of the public. Many epileptics are dangerous, both to themselves and to others. I do not in this statement refer to those who are insane in the legal sense, and can properly be committed to asylums for the insane. Every alienist, and all others skilled in dealing with such insane patients, will admit that they form, perhaps the most dangerous class of all insane. But of them, I do not speak. I mean, on the contrary, in this statement to include those epileptics who are subject to frequent severe attacks, but who, in the intervals between these attacks are in a condition of comparative sanity. Only a short time ago, I saw in company with Dr. Jelly, a patient of this character, who had a few days previously attempted to drown himself, apparently while in a so-called post-epileptic condition, that is, in an abnormal condition immediately following an attack. He seemed to have had a perfectly clear idea of what he wanted to do, but his reasons for doing it seemed to have been indistinct and vague. Between the attacks, including in this word certain temporary epileptic conditions as well as the actual convulsions, this person was sane, and we thoroughly agreed that it would be impossible to commit him to any medical institution. Yet such a patient is subject to conditions in which he may do violence to others, either under temporary delusions or without knowledge thereof. The patient mentioned is liable, for example, to lose consciousness of his actions for varying periods, and frequently recovers his senses to find that he has walked a distance of from twenty minutes to half an hour from the place where he was when he last recollects anything. There is no evidence that when in these conditions he appears otherwise than sane to those whom he meets. He is, however, apparently unaccountable for his actions at these times. It is in these conditions that non-insane epileptics become extremely dangerous. Such a person may attack, assault, rob, murder, or commit almost any other crime. Cases of this character are too well-known among medical men for me to relate them here. As an example, I will refer to the one related by Voisin, where an epileptic, without any cause, violently attacked a shopkeeper with whom he had previously had no acquaintance.

After an epileptic has committed a serious or savage crime, if it can be rendered probable that this was done under the influence of the disease, and that he was, therefore, morally irresponsible, he will generally be sent to some institution for the insane, at least for a time, and not improbably later set free, while still a source of danger to those about him. The release of the patient before he is apparently safe is, from the nature of our institutions, not altogether avoidable. The patient may be practically unsafe, and yet technically not insane. What, however, I would insist on, as most important to the community, is that those epileptics who are very liable to be dangerous, should be placed in a position where they can harm neither

<sup>1</sup> Read before the Massachusetts Medical Society, Suffolk District, Section for Clinical Medicine, Pathology and Hygiene, December 17, 1890.

themselves nor others involuntarily. This is only justice to the patients themselves; for their own sake they should be prevented from committing crimes even unconsciously. The mental suffering which may be caused by the unconscious or involuntary commission of a crime, is much greater than the annoyance and discomfort of carefully systematized protection. *Epileptics*, like the insane, must be protected from themselves.

These persons are as much members of the community as any others. They stand in the same relation as regards personal protection. Of mental suffering, although much more serious, the community cannot, as a rule, take cognizance, but from physical injury or danger, it is, within certain limits, its duty to protect all its members. It is its duty to protect epileptics from themselves. We must restrain them from suicide, and prevent them from injuring themselves as far as possible. The community also should be spared the shock of sudden accidents or deaths. It is only a few months since that an epileptic who had, from time to time been under my care, was drowned in the Public Garden Pond during an attack. I had searched in vain for a place where this man could be put in safety; there was no such in existence in the State. He was not insane, and was not a proper subject for an almshouse.

Such accidents as this are avoidable, and we all become more or less culpably negligent unless we consider what are the proper remedies, and take active measures to apply them.

Epileptics must be divided into classes as regards treatment. Many of the lighter cases do well under proper diet, exercise and drugs. Other cases, especially the traumatic ones, are helped by surgical means, and the secondary cases, which are hardly to be considered here, are often best treated by treating the primary cause. But when all these have been eliminated, there still remain those for whom some home is necessary, who are unsafe either for themselves or others, or are liable to be so. The best method of dealing with this class — of course I am speaking now only of the pauper and semi-pauper cases — is the institutional, but they must have an institution of their own. They should not be placed in an asylum for the insane, nor are they fit subjects for any almshouses or institutions for the poor, such as at present exist. This has long been admitted by all specialists and other physicians who have knowledge of this subject, and is too plain to admit of discussion.

But the best form of institution for these unfortunate is less settled. Various schemes have been proposed for their care. The first point to be determined and perhaps the most important, is the question of independence. These patients may be cared for in connection with patients of some other kind; they may form a portion of some other institution, preferably an asylum for the insane, and though entirely separated and forming a distinct ward or division, be under the same management and direction. This method has certain great advantages over any other, and has been advocated by some of the soundest experts in Europe. In the first place, it is cheaper. The larger the number of persons cared for, other things being equal, the less is the average cost; it, to a certain extent, according to the degree of dependence, avoids the necessity of separate establishments and thus in many ways, labor and expense are avoided.

The food for the whole institution may be cooked in one kitchen, the washing done in one laundry and the number of employees be less than would otherwise be the case. The superintendent of a large institution has more opportunity for observation and, if he has time, he can profit by his larger experience.

But, on the other hand, we are confronted here by a real difficulty and, as I believe, a well-founded objection to this method. Passing by the fact that our ordinary asylums and other institutions are already so large that the superintendents, even aided as they are by a corps of skilled and competent assistants, have as great a responsibility as they can bear, and more weight should not be put upon their already overburdened shoulders, it seems scarcely advisable that these men should be called to treat a class of patients whose management must be extremely different and, in some cases, diametrically opposite to that which they ordinarily use. The management of the insane needs a special training to which a man should devote his whole energies and faculty, and it is a loss whenever these are diverted in another direction. The management of epileptics in an institution, also needs a special training, and the two are not of a character likely to be combined. If the medical care and arrangements for the insane and non-insane epileptics are combined under one management, neither class is likely to be so well cared for, as if they are kept wholly distinct.

For these reasons, I should certainly not feel it wise that both insane and non-insane patients should be confined in the same medical institution, even in separate parts thereof, unless these parts should be practically distinct with different superintendents, medical officers and, as a whole, form separate establishments. In such cases all the advantages above mentioned are absent, and such establishments belong less to the class of dependent than to that of independent and unconnected institutions.

Believing for the above reasons, that separate institutions are advisable for the best care and treatment of chronic pauper epileptics, the next question to be considered is, what form of establishment or settlement for such persons is the best. Three arrangements have been advocated, and all have been in actual use. These are:

(1) A large building or institution of the same general character as our ordinary hospitals or asylums, to be used solely for epileptics. This may be one large building, or several large buildings, the essential factor being that a number of patients are congregated together under one roof.

(2) A series of small buildings — cottage hospitals — each containing only one or, at most, a very small number of patients. These buildings are all under one management.

(3) A colony resembling that of Gheel in Belgium, where the epileptics may be boarded out in families with whom they live and by whom they are cared for.

The value of these methods must be determined both by the experience of others and by special considerations. From the very nature of their affliction, special remedies and special conditions are demanded for these patients. They are in a different position from the ordinary sick and also from the insane, and cannot be placed in a common category with either. Until within late years — and even at the present time in this country — epileptics were treated exclusively either in hospitals with the ordinary sick, or in asy-

lums for the insane. The effect, therefore, of the treatment of epileptics in connection with other patients and with other epileptics, has been for a long time a matter of experience. The latter question, which alone concerns us now, has also been tested in special wards and hospitals. We find that the influence of epileptics upon each other is not as bad as might be *prima facie* supposed, that a certain number can be well cared for in a large building devoted to them, but that the majority cannot be so well managed when they form part of a community as when they live more separated. It is not found that the sight of epileptic attacks in another epileptic, is especially likely to induce them in the non-hysterical looker-on and the argument that this was the case which at one time obtained widely, is not valid. None the less, we ought to spare these afflicted as far as possible the mental shocks of such scenes, so much worse when they know that they are later to go through the same themselves. Very important, too, from a practical, medical point of view, is the danger which one patient labors under of being attacked by another. As before stated, non-insane epileptics when the epilepsy is severe are liable at any time to attack others, or injure themselves and often without any notice. This is the most weighty reason for their separation. Secondly and derived from this, is the reason that in large institutions, when many patients are brought together, the number of attendants is liable to be scantied and scrimped and, on the whole, not such as the most cautious would desire. On this account serious accidents may occur. Again, *open-air* employment is almost necessary for epileptics and this can usually be better arranged when they are not all herded into one institution.

For these reasons and also because a routine treatment is, except within certain narrow limits, unadvisable in these cases, there is no doubt but the cottage hospital system, or that of colonization, is preferable to that of one large building (the community system).

The respective merits of colonization and of cottage hospitals may vary somewhat under various circumstances. In certain countries, the cottage hospital system appears to offer decided advantages. In this system, the sick are under constant trained care, which under the colonization scheme, is well-nigh impossible. Such care not only lessens their liability to injury, but the security for their proper treatment and protection is much greater, no matter how careful the inspection under the colonization plan. In the latter plan, too, the danger from epileptics to others cannot be disregarded.

On these grounds, therefore, I have concluded that the cottage hospital system offers, at the present time, the best means for the proper care and treatment of chronic epileptics. But whatever means are used for this purpose, they cannot be properly cared for without the free expenditure of money. The primary requirement in forming any institution of this class, is that there should be no stinting of means. If such an institution cannot be carried on so as to fulfil its purpose, it had better not be undertaken at all. Waste of money is not charity, and that money is wasted, which being too small in amount, does not accomplish its purpose. No half-way measures should be attempted; they are liable to be worse than useless, as being not only ineffective, but obstructive to true progress in this direction.

## TWO CASES OF LAPAROTOMY FOR INTRA-ABDOMINAL HÆMORRHAGE.<sup>1</sup>

BY JOHN HOMANS, M.D.,

Surgeon to Massachusetts General Hospital, and Harvard University Lecturer on Ovarian Tumors.

CASE 1. In November, 1888, I was asked by Dr. W. T. Carolin, of Lowell, to see a married lady, twenty-three years old, who had been flowing almost constantly since the 14th of October.

The patient was a bright, intelligent woman, who stated that her weight had formerly been one hundred and fifty pounds, and was now but one hundred and fifteen. She had been married three years, and had never been pregnant. Before her marriage she was accustomed for many years to suffer from backache and headache. In 1883, she consulted Dr. O. W. Doe for dyspepsia and hysteria. In 1885, she was treated locally and generally for six months by Dr. Irwin, of New York, and also by Dr. Wood. In 1887, she consulted Dr. W. H. Baker, and also Dr. Gillette. During these years she had backache and soreness in the left iliac region, and was unable to walk any distance for two years on account of pain and soreness in the abdomen.

January 1, 1888, she entered St. John's Hospital, in Lowell, and remained there six months, under the care of Dr. Carolin. She felt somewhat improved when she left the hospital, and went to Martha's Vineyard, but she soon became tired and feeble. Later in the summer she went to the northern part of Vermont, and gained flesh and strength. In the autumn she came to Boston, and, after walking about a good deal, had a return of her former debility and suffering. About this time she began to wear a pessary, and on October 10th, went to Holliston, Mass., and walked a mile. The next morning she could hardly stand; and after hobbling about with pain in her left side and in her foot at every step she took, she removed the pessary and flowing at once began. This had continued ever since, with short intervals of cessation and pain. The color of the blood was mostly bright, and about four ounces a day by estimation.

I saw her on November 7th, with Dr. Carolin. I found the hemorrhage going on. On examination the abdomen looked normal. It was somewhat tender, particularly in the pubic and iliac regions, especially on the left side, where the percussion note was duller than elsewhere. Both lumbar regions were rather dull. There was great tenderness in Douglas's pouch. The os was virginal and healthy. A bunch, the size of an elongated Seckel pear, was felt in the left iliac region. She was suffering considerable pain, and for this she was given McMunn's elixir of opium; she also took aromatic spirits of ammonia and ergot. She had fainted away the morning I saw her; and I was told that she had fainted several times previously. Her pulse was 108, and her evening temperature 101°. She had been and was now having profuse night sweats. She fainted again on the morning of November 8th. I learned that her father was living at sixty-three, and her mother had died, at thirty, of typhoid fever; but her paternal grandfather and grandmother and uncles and aunts were reported to have died of consumption. Taking all these facts into consideration, the hemorrhage, fainting, tenderness, the pallor, the tumor, and more or less dulness on percussion in

<sup>1</sup> Read before the Obstetrical Society of Boston, November 8, 1890.

the pubic and left iliac regions, it seemed almost certain that hæmorrhage had been and was going on within the abdomen to an alarming degree.

Laparotomy was done on November 17, 1888. An incision at first two inches long was afterwards increased to four. On opening the peritoneum thin, fluid blood of a purple grape-juice color ran out, and it was evident that the lower part of the abdomen was full of clotted and liquid blood. This was sponged out, there being about a pint of fluid blood and many handfuls of clot, the true and false pelvis being filled with coagulum and bloody fluid. Each Fallopian tube was found to be the size of a forefinger, and was distended with blood. In each side of the pelvis was a cavity about the size of a peach, the walls of which were lined with coagulum, which was more or less adherent. The broad ligaments were tied close to the uterus on both sides, and the abdomen was patiently sponged out. Both tubes and most of both ovaries were removed; and, the bleeding having been entirely stopped, a drainage-tube was put in the abdomen to the left of the uterus, and the wound was dressed with iodoform gauze and absorbent cotton.

The patient was very feeble at the end of the operation, and was given several enemata of salt solution containing brandy, and two subcutaneous injections of brandy. There had been some arterial hæmorrhage during the operation, but not much. The right tube, which was first seen after the abdomen had been cleared of blood, was much larger than when it was removed, for it had been squeezed. The tubes were filled with fluid, dark blood, and clots, and were covered with old adventitious adhesions to the ovaries and broad ligaments.

Professor Fitz examined the specimens, and his report was as follows: "Both tumors weighed two ounces. The left Fallopian tube formed a sac with convoluted walls, the fimbriated end not appearing, lined with a reddish-gray, somewhat translucent membrane; there were no contents, as the dilated peripheral end had been separated from its attachments; at one part of the wall, near the uterus, was an adherent, nearly colorless clot the size of a pea. The ovary contained a cyst the size of a cherry. The right tube was dilated and convoluted, its walls thickened to about the size of the little finger; the contents were watery and scanty. The right ovary was adherent, but not abnormal. Diagnosis: chronic salpingitis and hæmato-salpinx."

It will be seen from the above description, that the hæmorrhage had come from a Fallopian tube which, chronically inflamed and softened, had been ruptured by the hæmorrhage within. There was nothing in the specimens to suggest a ruptured tubal pregnancy. The patient recovered, and was able to walk out in the course of a few weeks.

CASE II. On April 21th, 1889, I was suddenly summoned to Cambridge, by a telephone from Dr. J. I. Hildreth. I found there Drs. Morrill Wyman, Nichol and McIntire. I learned that Mrs. H., the wife of a physician in the State of New York, had been taken at 10 a.m. suddenly, without warning, with severe pain in the pelvic region and vagina, and with faintness, and complete collapse. Dr. Hildreth on his arrival could find no pulse at the wrist, the nails were blue and the extremities cold. The color of the lips and of the conjunctivæ was not bad. The attack of pain and faintness occurred about every half hour be-

tween the first seizure and the time I saw her, an interval of two hours.

I learned that Mrs. H. was thirty-two years old, and had been married two years. Her menstruation had been regular until March, when it was much less than usual. The catamenia were due at this time. I agreed that there was intra-abdominal hæmorrhage, and probably extra-uterine pregnancy. The abdomen was opened; and a large basinful of clotted and liquid blood, both dark and bright (at least two pounds) was removed from the abdomen. In the right Fallopian tube, about two inches from the uterus, was a rent leading into a cavity the size of a large pea. The tube was tied close to the uterus, and, with the ovary, was removed. The pulse at the wrist, which had been imperceptible since 10 o'clock, returned somewhat. At about 2.30 p.m. a transfusion of about thirty ounces of a warm solution containing fifteen grains of bicarbonate soda and two drachms of common salt to the pint, was done at the right elbow. The pulse returned and was moderately strong, but disappeared again subsequently. The patient became extremely restless, and died at 4 a.m., April 25th.

The immediate family of the patient would not consent to an autopsy, nor could I persuade the husband, who was a doctor, to insist upon one.

The specimen was sent to Dr. Whitney, whose report was as follows: "A Fallopian tube and ovary. The tube was about nine and a half centimetres in length; and at the end furthest from the fimbriated extremity was a cavity about the size of a walnut, with thin walls and lined with a slightly shaggy membrane. In the part next the continuation of the tube was a slight thickening, evidently due to the presence of clotted blood. Microscopic examination of the lining membrane showed the presence of a small stunted villi covered with large round cells, the structure in every way similar to that of the chorion. The ovary was slightly wrinkled, about twenty-one millimetres by nine millimetres thick. Near the outer free edge was a corpus luteum about six millimetres long."

#### A CASE OF TUBAL PREGNANCY, WITH RUPTURE AND FATAL HÆMORRHAGE AT AN EARLY STAGE.

BY F. W. DRAPER, M.D.,  
Medico-Legal Pathologist at Boston City Hospital.

I PRESENT the following notes, without extended comments, as an example of the most common variety of ectopic gestation, a departure from normal pregnancy which is always dangerous and generally fatal in its results. It is an illustration of a condition which calls for the highest obstetric skill and judgment for its correct diagnosis and successful treatment.

Jennie E., an unmarried house-maid, eighteen years old, was brought to the Boston City Hospital by ambulance one afternoon last August in a state bordering on collapse. She said she had always been well and strong and that this was her first illness. This sickness, she said, had begun about five weeks before with severe, cramp-like pains in the pelvic region at the time of her menstruation. The catamenial flow was lessened and had not re-appeared. Menstruation previously had always been regular but painful. She said that for two months she had had considerable headache

with loss of appetite. Vomiting had occurred for the first time the day before entrance to the hospital. She had been obliged to suspend work the week before and had seen a physician once, who made a superficial examination and gave only temporary relief. Her condition had taken a very decided turn for the worse on the day before she came under observation at the hospital.

At the time of her admission, the most important symptom was pain, severe in character, starting in the pelvis and extending down the thighs and to the back; at times, it was referred to the shoulders also. The general surface of the body, the lips and the tongue presented a striking degree of pallor. The pulse was small, 100, scarcely perceptible in the radial arteries; the heart-sounds were distinct but very weak. The respirations numbered twenty-eight per minute. The skin was cold. The temperature was subnormal. There was great restlessness. Thirst was a marked symptom. The mind was clear but apprehensive. The patient vomited repeatedly. There was constipation. There was no vaginal discharge of any kind.

Palpation of the abdomen developed extreme tenderness in the hypogastric region. There was no tympanites. Physical examination of the pelvic organs was not attempted.

Alcoholic stimulation was vigorously pushed without any success; the patient sank steadily, and died five hours after her admission to the hospital.<sup>2</sup>

Here, then, was a case, clearly alarming and desperate in character from the moment it came under medical observation, but in other respects sufficiently mysterious. Its clinical data was insufficient for a satisfactory diagnosis, and none was reached before the death. The cause of the obscure and puzzling symptoms might be any one of a dozen conditions; it could be guessed but not demonstrated during the patient's life. Irritant poisoning and fatal peritonitis resulting from criminal procedures were suggested as possibilities. In view of these possibilities, the case was referred for medico-legal investigation. The first and most natural step in this investigation was a post-mortem examination of the body, and this very quickly solved all the doubts which the case had presented.

The autopsy was made thirteen and a half hours after death. The body was well developed. An extreme degree of pallor of the surface at once attracted attention. The breasts were small and relatively undeveloped; the areolæ were without pigmentation or the tuberculous elevations of pregnancy. The external genital organs were very pale but showed no sign of recent injury. The ostium vaginae was small, admitting the thumb with some resistance. The hymen was absent.

When the primary section of the abdominal wall was made, blood (fluid and clotted) welled up through the incision. Three quarts of it were found in the peritoneal cavity.

The heart was pale, contracted and nearly empty; its ventricles contained only some small, stringy, partly decolorized clots. There was a small, indistinct, sub-endocardial ecchymosis in the left ventricle.

The lungs were dry and exsanguine.

The spleen, œsophagus, stomach, pancreas, intestines, liver and kidneys shared in the general anemia of the tissues, but were otherwise normal.

<sup>2</sup> For this clinical history, the writer is indebted to Dr. C. F. Folsom's courtesy, the case having occurred in his service at the hospital.

The vagina and bladder were extremely pale.

Around the os uteri was a narrow periphery of eroded mucous membrane, somewhat redder than the adjacent parts. The canal of the cervix was pale and intact. The size and shape of the os uteri were those of the virgin womb, and the womb itself was of normal size. The lining of its cavity was swollen, soft and velvety, with a well-marked uniform red color; the cavity was entirely empty.

The right tube and ovary were normal.

The left ovary was large, symmetrical, soft and red; at its inner extremity was a small cyst containing clear fluid; at its other end was a corpus luteum, with thick, pale yellow, convoluted wall and a clot of decolorized fibrin in its centre,—the whole being of the shape and size of a beech-nut.

The left Fallopian tube was distended in its outer third to the size and shape of a small olive. The wall of this sac was thin almost to translucency and was of a purple color; it presented at its upper and anterior segment, an irregularly circular opening, or rupture, of the size of a silver dime. Just outside this rent lay a clot of firm consistency, with some decolorized laminae. Within the dilated tube were some irregular masses, resembling blood-clot, adherent to the inner wall. The distal portion of the tube, toward the fimbriated extremity and beyond the cavity above described, showed moderate dilatation with marked reddening; that portion between the rupture and fundus of the womb was of normal appearance. Careful search was made in the pelvis and abdominal cavity and in the removed blood-clots, for any mass or substance resembling an ovum, but without success. If, however, the gross appearances observed at the autopsy left any shadow of doubt upon the post-mortem diagnosis of tubal pregnancy, that doubt was removed by the report of Dr. Henry F. Sears, to whom the pelvic organs were submitted for independent microscopic examination:

"There was a corpus luteum in the left ovary and decidua in the uterus. The left Fallopian tube was ruptured, and had adherent to its inner surface an irregular, rough, dark red mass, portions of which, showed, under the microscope, chorionic villi, thus establishing the diagnosis of tubal pregnancy. The fœtus was not to be found in the mass sent to me. Dr. C. S. Minot, to whom I showed the specimen, said it was probably between the first and second month of gestation."

This case suggests two questions:

(1) Recalling the fact that the patient was a young, unmarried girl, whose chastity had not been questioned, and whose menstruation had been regular, was it possible at any time in her past sickness, to establish a diagnosis of tubal pregnancy upon a reasonable basis?

(2) Assuming that such diagnosis was practicable, was laparotomy indicated as a justifiable procedure offering probable success.

In order that the changes produced in tuberculous tissues by Koch's fluid may be determined as accurately as possible, the directors of the Charité Hospital at Berlin have given orders that the bodies of any patients who may die after having been treated by the new method, shall be examined as soon after death as the law permits. Koch found such early examinations a great help in his investigations on cholera.

# A CASE OF EXTRA-UTERINE PREGNANCY; OPERATION AT THE NINTH MONTH; RECOVERY.

BY ERNEST W. CUSHING, M.D., BOSTON,  
Surgeon of the Women's Charity Club Hospital.

ON the 13th of October, 1890, in consultation with Dr. Frost, of Peabody, Mass., and Dr. Arthur Kemble, of Salem, I saw a patient of the former, a woman of thirty-two years, who had been married over ten years, without the occurrence of conception at any time. She had menstruated last February, but in April there was an irregular discharge, lasting, with intermissions, for several weeks. There were no subjective signs of pregnancy at any time; the breasts were, however, full and large, and contained abundant colostrum.

Examination of the abdomen showed a large irregular mass, somewhat to the right of the median line, and about the size of a child at term; in the right iliac fossa there was a softer mass, completely filling it, and continuous with the main body of the tumor. This part of the abdomen was very painful, and a placental souffle could be plainly heard, low down on the right; but the most careful auscultation failed to reveal any fetal heart-sounds. Dr. Frost, who had watched the case very carefully, and had noticed the placental souffle for more than a month, had never been able to detect any fetal heart-sound.

Examination by the vagina showed a rounded mass, of the size, shape, and hardness of the fetal head, above and behind the uterus. The small cervix, which could be felt, high up, behind the symphysis, appeared to be at right angles with this mass, which therefore seemed to be contained in the uterus. It did not seem possible to decide surely that pregnancy was present, in view of the utter absence of fetal heart-tones, fetal movements, uterine contractions, or any subjective symptoms of pregnancy.

Nevertheless, it was agreed that the probability was greatest that there was a pregnancy, either extra-uterine, or complicated by the presence of a tumor. As the woman was in good condition, able to be about, and well nourished, although suffering much pain, it was agreed to wait for some few weeks, before attempting any operation, unless some condition should supervene calling for interference.

On November 6th, I again saw the patient in consultation, and learned that for some ten days her condition had been decidedly worse; there was more pain, she was confined to her bed, could not take nourishment, had some elevation of temperature, and in fact was running down. Careful examination showed that the tumor was not in the uterus, which was crowded to the left, and toward the symphysis, and was of nearly normal size. The placental souffle was less distinct, fluctuation could be detected on the left of the tumor. It was agreed that probably extra-uterine pregnancy, with a dead fetus, was present, and that in any case immediate interference was required.

Operation on November 8th. The median incision, placed at the very border of the mass which lay on the right, and the peritoneum was found very thick and vascular. On passing the hand into the abdomen, it seemed as if the tumor must be malignant; but on carefully working toward the left, and separating the adherent omentum over the fluctuating part of the tumor, the thin cyst suddenly ruptured, and a large

quantity of foul, yellowish fluid was discharged with a great gush. The stench was almost intolerable. A moment later, on enlarging the opening, a full grown fetus popped out, breech first. It was dead and macerated.

The upper part of the cyst was found to consist only of the amniotic membranes, with adhesions, and adherent omentum, and very little of it could be removed. The lower part of the sac, however, was very thick, and apparently was formed of the Fallopian tube, firmly adherent to the tissues of the right iliac fossa. Half of the placenta was contained in this thickened part of the sac, and half was outside of it, extending on the under side of the abdominal wall to a little over the median line, and adhering to the omentum. This upper half of the placenta was in a state of fatty degeneration, and was easily removed, carrying with it the insertion of the cord, and tearing off so readily from the other half that I thought that I had removed the whole placenta. I was therefore distressed to find the other half, reaching far down into the sac, rather firmly adherent, and bleeding when detached. Nevertheless, I succeeded in removing it without serious hemorrhage, stuffing the sac with iodoform gauze. The insertion of the Fallopian tube, which joined the sac to the uterus, was now tied off, leaving the thick walls of the cup-shaped cavity free, except at the bottom, and low down on the right. I did not think it safe to try to remove this thick tissue, but gathered the upper margin of it into a sort of ring, which I sewed firmly to the lower part of the abdominal incision. The abdominal cavity was thoroughly washed out with hot Hygiea distilled water, and two glass drainage-tubes inserted; one to drain the peritoneal cavity was carried through a new small cut, to the left of the main incision, and passed to the left of the sac down to the space of Douglas. The other tube was carried to the bottom of the sac, and fresh iodoform gauze was packed around it. One part of the sac which could not be entirely brought up to the abdominal wall, was very carefully shut off from the abdominal cavity by the gauze.

The recovery was uneventful. The patient had no pain nor fever. The abdominal tube was removed on the third day, and the tube from the sac was taken out at the end of a week. The cavity of the sac contracted rapidly, being kept thoroughly clean and always full of iodoform gauze. Aristol was also dusted into the sac very freely. It never suppurated, but contracted and filled up, until only a small sinus remained, which gradually closed. The patient left her bed five weeks after the operation.<sup>2</sup>

Examination of the specimen showed that the child had passed the eighth month; it had apparently died from a tight double twist in the cord near the umbilicus. It was as large as most infants at birth. The specimen is now in the pathological museum of the medical school of Harvard University.

The title of the new journal devoted to the Koch treatment is *Central Zeitung für das Koch'sche Heilverfahren*. The first number appeared in Berlin on January 1st. From the prospectus it appears to be addressed more to the public than the profession. Professor Koch is, we understand, in no way connected with it.

<sup>1</sup> Reported in detail before the Obstetrical Society of Boston, Nov. 10th, 1890.

<sup>2</sup> January 4, 1891. She has entirely recovered.

RECENT PROGRESS IN DISEASES OF THE NERVOUS SYSTEM.<sup>1</sup>

BY PHILIP COOMBS KNAPE, A.M., M.D.

## SYPHILIS OF THE CENTRAL NERVOUS SYSTEM.

OPPENHEIM<sup>10</sup> holds that the commonest syphilitic process in the brain is a diffuse gummosus meningitis of the base, beginning especially in the neighborhood of the optic chiasma, and forming a thick mass in which the nerves are imbedded; this mass may also include the vessels, leading to narrowing of their calibre, and to subsequent thrombosis. The symptoms to which this gives rise are headache, vomiting, vertigo, spasm, and faintness. The mental symptoms are important, a moderate dementia, poor memory, and apathy, not the increasing stupor so common in tumor; this mental condition is also very often variable, to a period of normal consciousness succeeds a period of stupor, or a period of maniacal excitement or confusional insanity, or even of epileptiform seizures. Polydipsia and polyuria are also common. As might be supposed from the location of such a lesion ocular disturbances are common. Neuritis and post-neuritic atrophy are sometimes seen, and changes in the visual field are very common. Oculo-motor paralyses have long been recognized as very common, and disturbances of the other cranial nerves are to be expected. The striking feature of cerebral syphilis is its peculiar course, the inconstancy of the symptoms, and the frequent remissions; a remarkable instance of variations in the visual field during two years that the patient was under observation, showed great differences, from a marked peripheral contraction to homonymous hemianopsia. The affection of the vessels at the base, the artery of the fissure of Sylvius and others, leads to thrombosis, and to aphasia or hemiparesis, which may also be temporary; this is often on the opposite side from the cranial nerve affection.

Meningitis of the convexity is less common, and cannot be diagnosed with as much certainty. The two most important factors in the differential diagnosis from non-syphilitic new growths — the most important other cortical lesion is — the tendency to remissions, which is also seen in glioma, and the absence of symptoms of pressure and choked disc, due to the flat superficial character of the lesion. In meningitis of the convexity the prognosis is more favorable.

Syphilis is only rarely limited to the cord; when the cord is diseased it is usually affected with the brain. As in the brain the commonest seat of the disease is in the meninges, especially in the cervical portion. A syphilitic cerebro-spinal meningitis is regarded as the commonest form of syphilis of the central nervous system. The spinal symptoms are usually those of an acute or a subacute myelitis, but the co-existence of cerebral symptoms, and the irregular course of the disease render the diagnosis sometimes possible. Other important symptoms in diagnosis are disappearance and re-appearance of the knee-jerks, Brown-Séquard's paralysis, neuralgia, hyperæsthesia and rigidity of the spine, and sometimes disturbance of the temperature sense.

The prognosis of the spinal form is much less favorable than that of brain syphilis, which usually yields to treatment if recognized early. The fatal cases, in

the author's experience, have almost always been those where the cause was persistently denied by the patient, and not recognized by the physician until late in the progress of the disease. In cases of neurasthenia, with a previous history of syphilis, much harm may be done by mistaking the neurasthenic symptoms for syphilitic, and giving anti-syphilitic treatment instead of the proper treatment for neurasthenia. The absence of ocular symptoms, of symptoms of cortical lesion, and of the peculiar mental disturbances, and the presence of hypochondria, introspection, irritability and anxiety render the distinction comparatively easy.

## CEREBRAL TUMORS.

Oppenheim<sup>11</sup> reports twenty-three cases of tumor in the cerebrum, with a careful analysis of the symptoms. Eighteen of these were gliomata or sarcomata, three were cancerous, one tubercle, and one gumma. Only striking cases in adults, however, are admitted to the hospital. In three cases a diagnosis of tumor was not made, and in three others it was at first doubtful. Oppenheim lays great stress on the importance of frequent examination of the eyes, even up to a short time before death, for choked disc may be a late symptom; he also distinguishes between choked disc and neuritis. The changes in the nerve are of the utmost importance in diagnosis, and are of very frequent occurrence. In nephritis, however, the ophthalmoscopic picture may be that of neuritis, the retina showing no changes. In such cases, where there is uræmia or cerebral hæmorrhage, with a negative urine, the diagnosis may be very difficult. He holds that neuritis or choked disc is absent only in those cases where the intra-cranial pressure is only slightly increased. Next to changes in the optic nerve, stupor and somnolence are of great value in diagnosis. It is sometimes difficult to keep patients awake long enough to answer questions. Oppenheim then analyzes the cases to learn how far focal symptoms can be relied on for diagnosis. In twelve cases there were aphasic symptoms, in nine of which the left temporal or frontal lobe was involved. An exact focal diagnosis could not be made from the symptoms, however, as the seat of the growth did not correspond to the particular type of aphasia, and some of the tumors were in the basal ganglia. In two cases the tumor was in the right hemisphere, and in one of these the patient had become left-handed at the age of seventeen, which raises the interesting question as to the possibility of the transfer of the speech centre in youth. The same may be said of the value of motor symptoms in diagnosis. In a few cases the new growth affected the precise centre corresponding to the disturbance of motion, but in others the tumor proved more or less remote from the centre, or deep down near the basal ganglia. With the uncertainty that still obtains in regard to the localization of the sensory centres, it is obvious that sensory disturbances give no more exact information than motor. Local headache is an entirely untrustworthy indication of the position of a tumor, but localized tenderness on percussion has greater value. In four of these cases was a more or less accurate focal diagnosis possible, and operative interference could have been undertaken — about seven per cent. In view, however, of the uncertainty that still obtains in diagnosis, of the limited success that recorded operations thus far show, and of the small

<sup>1</sup> Concluded from page 10 of the Journal.<sup>10</sup> *Zu Kenntnis der syphilitischen Erkrankungen des centralen Nervensystems*, Berlin, 1890, also, *Berliner Klinischer Wochenschrift*, Nos. 18, 49, 1889.<sup>11</sup> *Archiv. für Psychiatric und Nervenkrankheiten*, xxi, 550, 705, xxii, 27, 1889, 1890.

percentage of cases that can be operated on (it must be remembered that, in this paper, Oppenheim deals only with tumors of the cerebrum itself), he considers that operative interference has a very limited field.

#### ENCEPHALITIS.

The work of recent investigators (Osler, Sachs) has afforded little pathological support of Strümpell's theory of a primary acute poli-encephalitis as a basis of a part of the cases of "cerebral infantile paralysis." Strümpell<sup>12</sup> has recently defended his views by an appeal to the clinical evidence. There is an affection attacking healthy children from the ages of one and a half to four years, beginning suddenly with fever, vomiting and headache, followed in a day or two by cerebral symptoms, convulsions, hemiplegia and coma. After recovery from the febrile disturbance certain cerebral symptoms remain, hemiplegia, convulsions, contracture, hemiatetosis, etc. These symptoms point to the cortex as the seat of disease. Chronic affections, defects in development, sclerosis and tumors may be excluded. Hemorrhage is rare in childhood, and is usually ushered in by apoplexy. Embolism is more probable, but a cause for embolism is often wanting, and embolism fails to explain the initial symptoms of fever, vomiting and malaise. There remains only acute encephalitis to account for the symptoms. This view is further supported by the study of two cases of primary acute hemorrhagic encephalitis in the adult. In these two cases the symptoms were very acute, a loss of consciousness, coming on during the night and rapidly increasing to the deepest sopor, and hemiplegia. Nothing could be learned as to the initial symptoms. There were exaggerated tendon reflexes, high temperature, and in one case a very rapid pulse. There was localized softening with hyperemia, serous exudation, emigration of white blood-corpuscles, and punctate hemorrhages. No embolism could be found, and there were none of the histological changes seen in softening after embolism. The process was regarded as an acute interstitial encephalitis. Granular cells, nerve swelling and other parenchymatous changes were absent.

#### SOUL-BLINDNESS.

Siemerling<sup>13</sup> reports the case of a man who suddenly, after an attack of vertigo, developed a peculiar disturbance of vision, resembling soul-blindness. There was a partial right hemianopsia and a difficulty in recognizing objects in the left fields, which, however, proved to be a partial left hemianopsia. The vision was one-third, and the color sense was lost. The line of division between the two fields was considerably to the right of the fixation point, the right (blind) field being the smaller. The sense of degree of light in the left field was normal. There was slight aggraphia and alexia. From the fact that the chief difficulty was in recognizing small objects, and an improvement in the symptoms as the color sense and the visual acuteness returned, it was judged that the failure to recognize objects was due to the partial left hemianopsia, rather than to any true soul-blindness, and this was demonstrated by producing similar symptoms in the reporter by illuminating objects with a monochromatic light when his own vision had been reduced to one-thirtieth by lenses.

The next report is a genuine case, where a man of

eighty, after several attacks of vertigo, was unable correctly to recognize objects, and complained of poor vision. Examination confirmed that he was unable to recognize ordinary objects by the visual sense, but that he could recognize them at once by the tactile sense. The memory was poor, but there were no other special cerebral symptoms except right hemianopsia. The vision was about one-third; the color sense, the power of measurement, the power of stereoscopic vision, the optical memory, the power of drawing and writing, and the sense of form were retained. The power to read was lost, the ability to find his way about was impaired, and the reaction time to visual impressions was impaired. There was no aphasia.

The writer holds that in every recognition there are two processes, a conscious perception of the visual impression, apperception; and a connection of this perception with other ideas, association. Soul-blindness may result from a disturbance of association alone, or from disturbances of both association and apperception; or, probably, from disturbances of apperception alone. The mixed form is commoner, of course, but the association disturbance often predominates. In the cortical visual apparatus are three factors, the subcortical tracts leading from the periphery, lesion of which causes amblyopic disturbances; cortical centres; and transcortical tracts connecting these centres with other parts of the cortex. Soul-blindness is due to a lesion of these last two portions. If in severe disturbances of the power of recognition the apperception and the optical memory are only slightly impaired, the lesion is transcortical; when the reverse occurs, it is cortical. Where there is partial defect of the still active half of the visual field, the lesion is cortical; without any defect, it is transcortical.

#### JACKSONIAN EPILEPSY.

Löwenfeld<sup>15</sup> raises the question whether partial or Jacksonian epilepsy is always due to an organic lesion in the brain, and, if so, does the symptom complex point to the seat of the lesion. Partial epilepsy in its typical form consists of convulsive movements beginning in a group of muscles, corresponding to certain cortical centres, and spreading to muscles supplied by adjoining centres, often attended with pain or sensory aura in the part first attacked, without the initial cry, and, if the convulsion be not general, without loss of consciousness or involuntary micturition. Such convulsions are seen with tumors, injury, and syphilis, but are much rarer in abscess, hemorrhage, and softening; they are seen also in encephalitis, parietic dementia, multiple sclerosis, uræmia, lesions of the peripheral nerves, hysteria, ordinary epilepsy, meningitis, and unknown causes. Moreover, when the attacks are due to organic lesions, the lesion itself need not be cortical, but it may involve the motor tract directly or remotely in the basal ganglia. Beside these typical cases of partial epilepsy there may be independent isolated attacks of sensory disturbances, pain or paræsthesia, or transitory paralyses, — sensory or paralytic "equivalents." The slightest cortical spasm contains an epileptic element as well as the slightest attacks of *petit mal* or sensory aura.

#### TRAUMATIC NEUROSES.

Hoffmann<sup>16</sup> has published an interesting article on

<sup>12</sup> *Deutsche Archiv für die Medizin*, clvii, 1, 1890.

<sup>13</sup> *Archiv für Psychiatrie und Nervenkrankheiten*, cxv, 1, 1891.

<sup>14</sup> *Archiv für Psychiatrie und Nervenkrankheiten*, cxv, 1, 1891.

<sup>15</sup> *Archiv für Psychiatrie und Nervenkrankheiten*, cxv, 1, 411, 1889.

<sup>16</sup> *Berliner klinische Wochenschrift*, July 21, 1890.

this subject. Out of twenty-four cases investigated by him, ten were genuine and eight were simulators; the other six had genuine symptoms but they exaggerated considerably and feigned additional symptoms. Three of the cases of simulation are given at length, where local hysteria, general traumatic hysteria, and general traumatic neurosis were feigned, and the patients had successfully simulated against the examination of several physicians. Only three of the ten genuine cases had contraction of the field of vision. Rumpf's sign, of quickening of the pulse on pressure on painful spots, was not looked for, as Rumpf had not then made it known. Hoffman claims that there is no method generally available for detecting simulation, but he holds that, with so great a percentage of simulation in his cases, doubt must be thrown on the rarity of simulation claimed by Oppenheim and Strümpell. Exaggeration is certainly not uncommon, and is often due to the fact that the patient's statements as to his illness are not believed. These neuroses are of varying sorts, and are seen more commonly after slight injuries than after severe physical concussions. The courts afford an admirable school for teaching the symptoms and for increasing the number of claimants.

## CHOREA.

Meyer<sup>17</sup> has analyzed the cases in the Berlin Charité. Six-tenths of one per cent. of all children treated in five years had chorea—121 cases, of whom nine per cent. had rheumatism, thirteen per cent. heart-disease, and two per cent. the two combined. Chorea, he holds, is a symptom, like convulsions, due to various causes. It may be a disease in itself, a neurosis due to psychical causes; it may arise from organic brain disease; or a disease, due perhaps, to a rheumatic virus, which has for its symptoms, rheumatism, heart-disease and chorea.

## Clinical Department.

### GYNECOLOGICAL CASES AT THE CARNEY HOSPITAL.

SERVICE OF DR. F. W. JOHNSON.

## CÆLIOTOMY: REMOVAL OF OVARIES AND TUBES.

H. C., single, twenty-one years of age, entered the hospital, surgical side, January 19, 1890. Through the kindness of Dr. M. F. Gavin, I got from the records the following history. She was delivered at the Boston Lying-in Hospital two months before she entered the Carney. Child and patient well until four days before entering when left breast became sensitive. Physical examination by Dr. Gavin showed swelling, redness and fluctuation of upper and outer segment of left breast. Abscess opened and drainage-tube inserted.

January 24th. Right breast having undergone abscess formation, it was incised and drainage-tube inserted. The chart shows the pyæmic state of the patient.

February 18th. Erythema on both sides of the face and on both arms.

March 22d. Transferred to Gynecological Department for treatment of salpingitis. On examination April 1st the uterus was found drawn over to the right side of the pelvis, and held there by adhesions. Tubes

and ovaries were prolapsed down into the posterior cul-de-sac where there was great sensitiveness. Constant occipital and frontal headache deprived her of sleep. Dizziness, dyspepsia, backache and almost constant pain in lower part of abdomen. The above rendered her almost bed-ridden. For two months hot-water vaginal douches were daily used with the application of tincture of iodine twice a week to the posterior cul-de-sac. The only gain was removal of post-uterine sensitiveness. Here was a poor servant girl with no friends in this country, and obliged to depend on her own resources to keep her out of the poor-house. Considering her miserable condition it was evident that she soon would be added to that long list of paupers, and become dependent on the State.

With this in mind Drs. Gavin and Elliot saw her with me, and agreed that removal of ovaries and tubes offered her a good chance of getting back her health and strength.

Two days after the consultation cœliotomy was done by me. Dr. Conant assisted. Dr. Gavin was present. An incision three inches long was made through the skin, the opening through the peritoneum being just large enough to admit the index and middle fingers. Tubes and ovaries were found fastened by adhesions. These were quickly freed and without clamp, after Tait's method, ligatures were placed and both ovaries with as much of the tubes as was possible, were removed.

Report by Dr. W. F. Whitney, on both ovaries and parts of the Fallopian tubes. The latter and the ligament connecting them with the ovaries presented nothing abnormal. The ovaries were slightly increased in size. The surface in general, smooth with an increased transparency as from the presence of fluid in the interior. Section showed the presence of numerous smooth-walled cysts of size varying from a pin's head to a large pea. Most of these were filled with a clear watery fluid, while some of the larger ones contained a firm, dark red coagulum. Microscopic exam-

<sup>17</sup> Berliner klinische Wochenschrift, July 14, 1890.

ination showed a few Graafian follicles, and the cyst walls showed evidence of fatty degenerated cells similar in shape and color to those of the *corpora lutea*. The fibrous tissue seemed increased especially on the outer surface. Diagnosis: retention cysts and chronic fibrous thickening.

Dr. Whitney wrote as follows: "As you will see from the description of the specimens received this afternoon, the ovaries were extensively disorganized by the presence of retention cysts and fibrous thickening. Whether they were incapable of further function is doubtful as evidence of Graafian follicles were still found. The association of these retention cysts with painful menstruation certainly seems more frequent than mere accident would seem to warrant."

Convalescence was without a drawback.

Within ten days the old abdominal pains had ceased and have never returned. The dyspepsia got well and the constipation cured itself. But it was two months before the head symptoms disappeared. She is now doing kitchen work, sleeping well, eating well, and feeling well. Certainly a very gratifying result.

#### COELIOTOMY: MULTICULAR CYSTO-ADENOMA.

H. S., single, twenty-two years of age, entered the hospital July 26th. She was sent to me from the western part of the State. She was a pale, thin, sickly-looking subject. For five months she had noticed that her abdomen was increasing in size. General health as good as it had been for years. On examination it was found that the uterus was right laterally retroverted. The abdomen contained a smooth non-fluctuating but elastic tumor extending above the umbilicus.

July 30th. Coeliotomy was done, Dr. Conant assisting. A cyst without adhesions was found growing from the left side. It contained one gallon of fluid which escaped readily through Tait's trocar. The pedicle was crushed by a Dawson clamp, tied with the Staffordshire knot, and the emptied cyst cut off. The right ovary was removed. Convalescence was without a drawback.

Report by Dr. W. F. Whitney. — I. A large relatively thick-walled smooth cyst, with evidence on the inside of trabecular showing the existence of previous secondary cysts. The wall was fibrous in structure with small cavities lined with cylindrical epithelium. Diagnosis: multilocular cysto-adenoma. II. The other ovary was enlarged. Its fibrous tissue stroma increased and there were two or three retention cysts. Evidences of *corpora lutea* were present in deep orange-colored spots. Beyond the fibrous thickening there is no evidence of disease.

In the following eight cases the Alexander-Adams operation was done. In six of the cases there was backward displacement with adhesions. In one case the left ovary was prolapsed into the posterior cul-de-sac and fastened there by adhesions so that no pessary could be worn to correct the existing retroflexion, and in one case there was right lateral displacement.

Lateral displacements, retroversions and retroflexions with adhesions, are among the most difficult cases we are called upon to treat.

At times packing in the Sims's position persistently carried out, will overcome adhesions between ovary and tube, or ovary and tubes, and peritoneum covering uterus, broad ligaments, or rectum; then the uterus can be replaced and kept in position by a pessary.

Still there are other cases where the adhesions will not yield to packing. In my experience these cases give a history of septic peritonitis following an abortion or severe vaginitis. This class has tried the patience of most everybody.

The old way, and the method that has been so much in use for years, is to gradually, by means of a uterine sound, replace the uterus, attempts being made every few days until the obstacles are overcome. It has been found in no small proportion of these cases that this use of the sound as a lever, was followed by a lighting up of the old trouble with the formation of new adhesions, and it was weeks or months before the pelvic organs were in a condition to be again subjected to the same treatment. This method has also been employed while the patient was under ether, the adhesions being broken up through the vagina and rectum by the fingers instead of by the sound. Peritonitis to any extent does not follow this procedure, but unless a pessary is put in to keep what has been gained, new adhesions will form holding the uterus out of place and perhaps more firmly than before, and unfortunately very few will tolerate a pessary immediately after the breaking-up of adhesions.

Another method is to do coeliotomy, break up all adhesions, and do ventral fixation of the uterus. This operation I have done in various ways with excellent results. In one case only did the uterus return to its former position, and this took place three months after the operation.

The great objection to this procedure is that it necessitates opening the peritoneal cavity. For nearly a year I have been treating in the following manner cases of backward displacement with adhesions, and cases of backward displacement where there were no adhesions, but where a pessary could not be worn owing to the contraction of some old effusion in the broad ligament, usually the left.

Under ether the uterus is replaced, all adhesions being gently but thoroughly overcome by manipulations with the finger through the rectum, and it is surprising how readily this can be done. Then, while the uterus is held in position by an Emmet's retractor, the cervix being pushed well back into the posterior cul-de-sac, an Alexander-Adams operation is done. The uterus is thus held upwards, non-flexed, and forwards while the raw surfaces are gluing to the peritoneum.

I have done the operation many times and as yet no uterus has retroverted and in no case has peritonitis been set up. If time shows the results to be as good as at present, it seems to me that it will be the proper operation for such cases after packing, faithfully tried, has failed to overcome the adhesions.

Dr. J. W. Elliot kindly did for me the first Alexander-Adams that I ever saw. Some months afterwards Dr. F. B. Harrington did another for me. At this time through the kindness of Dr. W. M. Conant, I had the opportunity of seeing several dissections for the round ligaments at the Harvard Medical School. I was surprised to see how far forward the fundus uteri was tipped when the ligaments were drawn out and the anterior surface of the broad ligaments was brought against the internal rings. So securely and evenly are the rings closed it occurred to me that the Alexander-Adams operation might be done for the radical cure of hernia. But what surprised me more than anything else was the way in which the prolapsed ovaries and tubes were drawn up into their proper place. I have

had satisfactory proof on this point in the living subject.

I was astonished at the ease with which the ligaments were found in my first case. The next case I saw was a most difficult one, there being no external rings as far as touch or the eye could make out. This case was operated on by Dr. Conant and it was very instructive to me. Knowing his anatomy so well he was not at a loss what to do but cut down directly into the canals and found the ligaments.

On the assertion of one of the best anatomists I make the statement that the round ligaments are *never absent* in a developed woman. After an experience with twenty odd cases I assert that the ligaments can *always* be found if the operator knows his landmarks and the subject is not undeveloped. The ligaments may be so small before being drawn out that it is necessary to catch them with artery forceps to prevent losing them, and I have seen them as large as my little finger. They are found in a fat subject as easily as in a thin one.

Cut boldly down to the aponeurosis, which cannot be missed. Stop all bleeding as you go along so that your aponeurosis may be kept white and glistening. Clean up the fascia and then with the index-finger on the spine the ligament will be found without any difficulty.

Attention to cleanliness should be the same as if coeliotomy was being done as it may be necessary to free the ligaments from adhesions throughout the whole length of the canals and the peritoneal cavity may be opened, then, too, healing by first intention is the desideratum. The following is the way in which the patient, instruments, ligatures and sponges are prepared.

Forty-eight hours before the operation one ounce of castor oil is administered. The day before the operation the patient is kept in bed and fed on gruel. On this day she is given a hot bath, the lower abdomen and pubes are thoroughly washed, first with soap and water, then with ether, and finally with a 1 to 1000 solution of corrosive sublimate. A compress of absorbent cotton thoroughly wet with a 1 to 3000 solution of corrosive sublimate is fastened on the abdomen and pubes by a binder and T-baudage, and allowed to remain until the operation. Two hours before the operation two ounces of whiskey are given by the rectum; and one hour before administering the ether, one one-hundredth grain of atropia is given by the mouth. In over a year's experience with atropia it has been found that when it is administered as above, seven-tenths of the patients do not vomit on coming out of the ether, and in part, or wholly it prevents the filling up of the mouth and fauces with mucus.

Just before being placed on the table the urine is drawn. Everything about the patient is clean. The abdomen and pubes are again washed with soap and water, the lower abdomen and pubes are shaved, and the parts again washed with a solution of corrosive sublimate, 1 to 1000, the hands and arms of assistant and operator are thoroughly washed with soap and water, then scrubbed in a 1 to 1000 solution of corrosive sublimate. Special care is taken to clean the finger nails. Towels wrung out of a solution of corrosive sublimate (1 to 1000) are placed about the field of operation.

The instruments after being thoroughly cleaned with hot soapsuds and wiped dry, are baked in the instrument pan, in an oven for three hours at a temperature of 330° F.

Catgut, silk, and silk-worm gut can be used in suturing the ligaments to the rings. Catgut is the only one of these that is absorbed. The catgut, silk, and silk-worm gut, are placed in ether for ten days; then they are put in glass jars containing a 1 to 1000 alcoholic solution of corrosive sublimate. They are kept in this solution one month before being used, and are used directly from this solution.

The sponges are made, as directed by Dr. J. W. Elliot, of wool tied up in suitable pieces of fine muslin, from which all starch has been removed. They are kept for weeks previous to an operation in glass jars containing a 1 to 1000 solution of corrosive sublimate.

Cut so that the lower end of the incision shall stop just over the pubic spine. Separate the nerve from the ligament, being careful not to injure it by rough handling or by sewing it to the pillars of the ring. Until experience has taught just how far it is safe to draw out the ligaments it is well to make a vaginal examination, the ligaments being kept taut before they are fastened. The slack of the ligaments may be cut off near where it is fastened to the rings and entirely removed, or it may be folded into the wound and fastened there by the sutures that close the incision, or it may be tied in a hard knot to the slack of the opposite side and both buried and sewed into the incisions that have been prolonged so as to meet. I prefer the first method as the ligaments are so often crushed and bruised in getting them out that their vitality is so much destroyed that suppuration takes place. After the sutures are tied, silk-worm gut being used to close the incision, iodoform is thickly sprinkled over both lines and kept in place by strips of baked gauze secured by collodion. Then several layers of baked gauze are placed on the lower abdomen and pubes, and on these several sheets of wadding. The whole is kept in place by an abdominal binder and perineal straps. The patient is kept on her back for a week, at the end of which the worm-gut is removed.

CASE I. R. G., married, aged twenty-three, entered the hospital March 24th. She complained of backache, pain in lower abdomen, burning sensation during micturition, and a profuse vaginal discharge. There was a history of gonorrhoeal peritonitis. Examination showed vaginitis, retroflexion with adhesions, and prolapse of both ovaries and tubes. Removal of both ovaries and tubes was advised, but she declined.

April 12th. Dr. Conant and myself worked one hour in breaking up the adhesions. Then the uterus was held up in place and the round ligaments drawn out and fastened to the rings. The ligaments were adherent throughout the canals, and were torn almost to shreds in freeing them.

In forty-eight hours there was redness and tenderness in line of right incision; temperature 102.4°. Next day tenderness was more pronounced; menstruation begun; and the temperature dropped to 101.8°. Two days later, the temperature still continuing high, Dr. Conant advised opening up the wound. The right ligament had been so much crushed that its vitality had been destroyed, and it was the starting point of the suppuration. The ligament had sloughed down to the point where it was fastened to the pillars of the ring. The wound was kept packed with iodoform gauze, and slowly healed up.

Examination two months after the operation found the uterus in good position.

**CASE II.** O. G., married, aged forty-two, entered the hospital April 14th. Had had eleven children and two abortions. Last child was born in 1888. She complained of backache, dragging and sagging in lower abdomen, headache, and constipation. Examination showed left lateral laceration of the cervix, retroversion and ruptured perineum. The vaginal walls were lax, and shortening of the round ligaments was advised in preference to three operations on the vagina. The anterior lip of the cervix was hypertrophied, extending through the vulva.

April 19th. Three-quarters of the anterior lip was amputated, the vaginal mucous membrane covering the stump being sutured to the membrane lining the canal. The uterus was replaced, and the round ligaments shortened. The right ligament was adherent throughout the canal.

Sixteen days after the operation a silk-worm suture that had been used in ligating an artery worked itself towards the surface and produced a superficial abscess. The results were good. She is to return in the fall to have the lacerated cervix sewed up.

**CASE III.** E. H., married, aged thirty-five, entered the hospital May 8th. She complained of backache, sagging and dragging in lower abdomen, and leucorrhœa. She had had four children, and one abortion at three months in January.

Examination showed laceration of the cervix, rectocele, ruptured perineum, and prolapse of left ovary. The uterus was drawn over to the right side of the pelvis. She had been treated for some time in the Out-patient Department, but the uterus could not be pushed away from the right side of the pelvis by packing.

May 12th. Operation. The cervix was operated on first; then Hegar's operation was done on the posterior wall; and finally the round ligaments were drawn out, the uterus being forced beyond the median line towards the left. A good result was obtained from each operation. When examined three months afterwards, the uterus was found in the median line and in its proper position.

**CASE IV.** M. M., married, aged twenty nine, entered the hospital May 24th. She complained of sterility, backache, dragging in both ovarian regions, constant leucorrhœa, constipation, and painful menstruation during the first day of the flow. She had been married two and one-half years and had not been pregnant.

Examination found retroflexion with prolapse of left ovary, which was adherent to the uterus at junction of body and neck. The left tube was in the posterior cul-de-sac. The right ovary was adherent to the upper part of the uterus, and there was stenosis of the cervical canal. After using the packing for a few times the uterus was replaceable, but owing to the fixed position of the ovaries, a pessary could not be worn.

June 1th. The cervical canal was dilated, and after all adhesions had been separated, the round ligaments were shortened. Good result.

**CASE V.** M. R., single, aged thirty-five, entered the hospital June 1st. She complained of severe dysmenorrhœa, obliging her to keep her bed the first day of the flow; pain in back for past two months; dragging in lower abdomen; pain in left ovarian region; leucorrhœa since puberty; and constipation.

Examination showed retroflexion with adhesions, and left ovary prolapsed and adherent.

June 2th. Operation. It was with the greatest difficulty that the adhesions were broken up and the

uterus replaced. Dr. Conant worked at least three-quarters of an hour in accomplishing this. After the adhesions were separated, it took me seven minutes to find and draw out the left ligament, and ten minutes to find and draw out the right ligament.

Eleven days after the operation a superficial abscess formed on the left side. The result was perfect as far as the position of the uterus was concerned. There was no elevation of temperature.

**CASE VI.** K. G., married, aged thirty-four, entered the hospital July 24th. She complained of sterility, painful menstruation, and backache. Examination showed conical cervix, stenosis of cervical canal and retroflexion with adhesions.

July 26th. Cervix dilated, and round ligaments shortened. Adhesions yielded readily. Result perfect.

**CASE VII.** C. K., married, aged thirty-four, entered the hospital October 4th. She complained of sterility, burning in left ovarian region for two years, and leucorrhœa since marriage. On examination a conical cervix and retroversion with adhesions was found. An attempt to dilate the cervix was made, and the round ligaments were shortened. There was no trouble in overcoming adhesions. Good result.

**CASE VIII.** C. B., married, aged thirty-three, entered the hospital September 15th. First labor February last. Face presentation. Instruments were used after hours of severe pain. Child was still-born. Long and tedious getting up. A few days after confinement urine escaped per vaginam. In a week or ten days leakage through the vagina ceased.

Examination showed retroversion with adhesions, extensive bilateral laceration of the cervix, and a cicatrix on the left side of the vagina, extending from the cervix almost to the vulva. At its middle it was firmly fastened to the bone. After packing for some time the uterus could be replaced, but owing to the cicatrix a pessary could not be worn.

October 16th. Emmet's operation was done on the cervix, and the round ligaments were shortened.

In this case there were no external rings to be seen or felt, and the ligaments were adherent throughout the canals. Two weeks after the operation an abscess was opened on the left side.

November 14th. Nine sutures were removed from cervix. Union perfect. Examination found the uterus in normal position.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOL- OGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MEETING of December 17, 1890.

DR. W. N. BULLARD read a paper upon

THE CARE OF CHRONIC PAUPER EPILEPTICS.<sup>1</sup>

In opening the discussion of this subject, DR. L. W. BAKER, of Baldwinville, Mass., called especial attention to the necessity for the care of epileptics. To any one familiar with the manifestations of epilepsy, there could, it seemed to him, be no question as to the desirability of providing separate accommo-

<sup>1</sup> See page 25 of the Journal.

ditions for the care and treatment of this unfortunate class of cases. The unearthly cry, the sudden fall, the distorted features, the foam-covered lips, the wild contortions, the death-like stupor, all present a picture which no insane or nervous person, or, indeed, any one not possessed of the stoutest nerves, ought to witness.

To my knowledge, the only institutions, aside from the almshouses, in which adult epileptics are received, are those devoted to the care of the insane, and usually they are not sent to these institutions until they present some manifestation of mental impairment or derangement which renders them unfit or unsafe to be at large in the community. During their residence in hospitals for the insane they are not, so far as I have been able to ascertain, provided with any separate accommodations, but are allowed to mingle with the other patients, and are classified only with regard to the mental symptoms which they may present. The great majority of epileptics are not insane, and it is a serious problem to provide these with suitable care and treatment. Certainly the insane asylum is no place for them, for the insane ought never to witness the wild contortions of an epileptic seizure; the effect in many instances might be very injurious.

Our hospitals for the insane are doing a distinct class of work, and their equipment is intended only for the treatment of mental disease. They were never designed for the treatment of epilepsy any more than for the treatment of dipsomania; and to send an epileptic or a dipsomaniac to one of these institutions is a manifest injustice. Epileptics are certainly entitled to proper care and treatment. They rightfully resent the companionship of the insane; and to compel these two classes to associate together is as unjust to the one as it is detrimental to the other.

In the medical profession the opinion generally prevails that epilepsy is an incurable disease. Granting for a moment that the popular idea is correct, is not the same equally true of many other diseases, the severity of which we are able to materially relieve by judicious care? How often has treatment removed an aortic obstruction, or a non-syphilitic cerebral tumor, or restored lung tissue in the last stage of phthisis to a normal condition. Yet who will maintain that medical care is of no value in these, as well as in many other chronic affections?

Dr. Powers, of London, gives the results of his treatment in 562 cases of epilepsy. Of these, the attacks ceased in 241 cases while under treatment. In 266 cases improvement short of arrest was obtained, the fits being reduced to one-twentieth, one-thirtieth, one-fiftieth, and even to one-two-hundredth of their frequency and severity. In 55 cases there was but little or no improvement.

My own experience has been that treatment will diminish the frequency as well as the severity of the attacks in the majority of cases; and even if we accomplish nothing more than this, are we not doing a great deal for the comfort of our patient? But the best results in the treatment of this disease will be obtained in institutions where the patient can be kept under observation for a long period of time, and where injurious influences are eliminated as far as possible. One advantage, among others, which the long-continued treatment of epilepsy will secure, is the administration of the necessary remedies with unflinching regularity, and the proper regulation of the patient's diet, two most important factors in securing a favorable result.

No one who has not had practical experience with an epileptic can realize the constant strain which such a patient occasions in the family to which he belongs. If for no other reason than the relief of the friends, provision should often be made for their care away from home. I am, of course, willing to admit that in many adult cases of long standing, we may fail to control the attacks. Unfortunately, also, we do not succeed in securing any improvement in the mental condition of many cases of insanity; but, nevertheless, we neglect no provision which can make them comfortable, and at least prevent the transmission of the insane diathesis to a later generation. So it should be with epilepsy.

According to Niemeyer, there are about six epileptics in every thousand individuals; another estimate places them at two in every thousand; yet there is not in this country a single institution devoted entirely to their care. There is one at Baldwinville, and another at Elwyn, Pa., where separate accommodations are provided for epileptic children; and these institutions are doing a good work. But there is absolutely no provision for adult epileptics aside from the insane asylums and almshouses. Even when the patient or his friends are able to pay for his care, the doors of other institutions are closed against him; for it is impossible to have these patients associate with others.

I once had a cottage filled with mild private cases of epilepsy, but was compelled to send them away on account of its close proximity to another cottage in which there were other patients; and I have often been obliged to refuse to receive these cases for this reason; and when further asked to recommend some institution where they can be received, I am obliged to confess my ignorance. I know a young lady, thirty years of age, with mind slightly impaired, easy to care for and seldom having a convulsion. She is able to take entire care of herself in-doors, but on account of an invalid mother, she cannot remain at home. Her friends are able to pay a moderate sum for her maintenance; but I know of no institution except an insane asylum which will receive her. I have met with other very similar cases, as have doubtless many members of this Society; and we are always at a loss to know what to do for them.

It would seem as though every hand was against the epileptic. Denied admission into general hospitals, expelled from the schools, shunned by society, almost an outcast from even his own family, the unfortunate victim of one of the most dreadful of maladies, finds no refuge or help except in the almshouse or insane asylum. This ought not to be. We humanely provide for every other defective class. The deaf, the dumb, the blind, the feeble-minded, the sick and infirm, all find care and medical treatment adapted to their special needs. Why should we longer refuse equal privilege for the thousands of epileptics in this country who are to-day suffering for lack of proper care.

In our provision for this class we are far behind other countries. At Biedfeldt, Germany, there is an epileptic colony, now numbering over 1,000 patients, and which has, during the twenty-three years of its existence, provided for over 2,500 epileptics. Dr. Peterson, of New York, visited this colony in 1887, and his description of the same, published in the *Medical Record* of April 23, 1887, is worthy of your attention. Similar institutions are now in existence in other parts of the Continent, and are doing good work.

I am not sure that the system of colonization is the one best adapted to the requirements of this country, but I am very positive that some provision should be made for the separate care and treatment of this class of cases.

In arranging accommodations for epileptics, special attention should be paid to their peculiar requirements. An attack is liable to occur at any moment and the house and furniture should be constructed so as to diminish, as far as possible, the liability to injury from falls. A variety of suitable occupations should also be provided, as during the intervals between the attacks the majority of epileptics are able to work, and the cost of their maintenance may thus be materially reduced.

Massachusetts has recently taken a step in advance of other States by providing for the separate and special care of the inebriate, thus relieving the asylums for the insane of a class of patients for whom they have no proper accommodations; and I hope that we shall soon have the added honor of establishing within her borders the first institution in this country devoted entirely to the care and treatment of epileptics. Then it may be that the scientific study of this disease will furnish us with better facilities for its successful treatment than we now possess.

DR. BULLARD asked Dr. Baker the number of patients for whom prospective accommodations have been planned at Baldwinville.

DR. BAKER replied that the present plan was intended to afford accommodation for one hundred and fifty additional inmates.

DR. BULLARD asked the number of applications thus far received for admission to the ward, when completed.

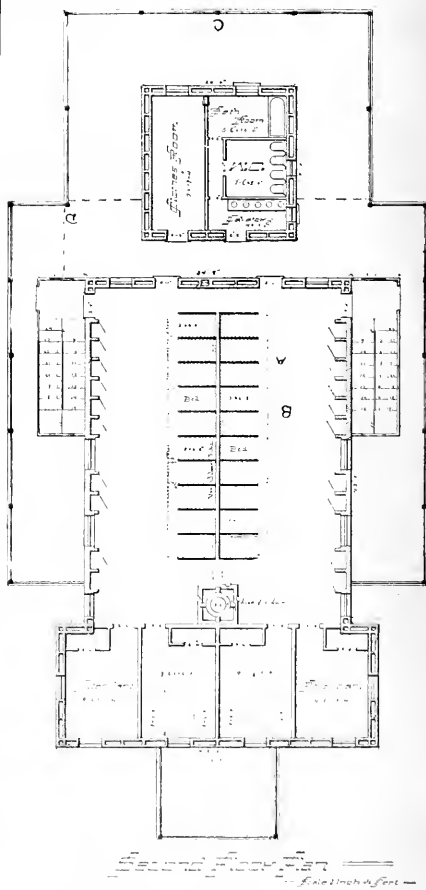

DR. BAKER said that about *four hundred applications* are at present on file in his office.

DR. EVERETT FLOOD, Superintendent of the Hospital Cottages for Children, Baldwinville, Mass., described a plan for caring for epileptic young men and women, which was shown in connection with Dr. Bullard's paper on the subject.

This is a plain, rectangular building of brick, with two stories, an attic and basement. The basement contains a furnace-room, coal-room and hot-water heater, on one side; and a kitchen, store-room and refrigerator, on the other; both sides open in the rear on a level with the ground. The front of the building is graded up three or four feet. The first floor contains a room for the matron and one for the assistant three sitting-rooms for patients, and a dining-room. The attic may have a room for a night-watch and one for a domestic, if these persons are needed. The second floor is shown.

There are stalls for sleeping, constructed on a middle-brick wall. They are divided by plank partitions, which may be provided with some padding or not, as the case requires. The partitions run out five feet, and extend to the ceiling. Each stall is three feet wide, but admitting a made-up bed which runs on rollers. When the bed is to be made, it can be drawn out from the stall, made up, and pushed back in place. When the patient is to go to bed, he undresses at the wall closet opposite his bed; hangs his clothing in the closet (which is a ventilating shaft with openings round the base board), takes his night garment from the same closet, where they have been during the day; shuts the closet door, and gets into bed over the foot,

which projects a little beyond the partition. Each stall ventilates at the upper back corner into a main shaft which connects with the chimney. At A and B there may be, if desirable, a double partition holding a sliding door, or a folding partition, so that these beds may be quite separate from all the others, if needed.

From the foot of the stairs back to C the piazza is covered, and at D a lattice partition extends round to the rear, giving a place for airing rubber sheets, setting pails, mops, etc. At D also may be a glass partition running to the wall of the main building, so that that part may be shut in during the cold weather. The plumbing is all in the little building at the rear, which has lavatories, bath-rooms, water-closets, etc., on the three floors and basement, and on top supports a tank for the water-supply. The hoods in the chimney give a safe place to burn a lamp all night.

Such a building may be erected for \$8,000, and will house twenty-four patients. Dr. Knapp tells me that he saw in Turin a ward on a similar plan, though

the stalls do not there run to the ceiling, and are not specially ventilated, nor do they exactly fit the bed.

Modifications of this plan can be easily made to suit the conditions; but the three essential features are the stalls, the ventilating-closets, and the separate building for all the plumbing, making the plumbing very simple and cheap. If not in connection with a plant, the basement of this building, which is all above ground, could be used for a laundry.

DR. A. R. MOULTON, of the State Board of Lunacy and Charity, said: The reader, in his exhaustive and conclusive paper, has so thoroughly discussed the subject under consideration that little remains to be said. I would, however, remark that in caring for pauper epileptics, I would not confine my treatment to chronic adults, but would seek to relieve those in the ranks from which the adults are drawn; the children and new cases, therefore, should have the earliest and most thorough treatment.

As the Commonwealth has already expended \$85,000 at Baldwinville, and practically owns the buildings there, it would be but a step to assume entire control of the establishment, and erect suitable detached buildings, on the spacious farm, for adults. At present, only children under fourteen years of age are admitted to that excellent hospital, yet it is only a question of time when those children will be full grown, and provision there or elsewhere must be made for them. The patients at Baldwinville cannot, as they become adults, be turned out of doors; therefore it seems to me that, if provision is to be made for chronic adults of the class under consideration, the most rational and economical measure would be to extend an already existing institution. At the place indicated, the railroad accommodations are good, land is cheap, the location is healthful, and the superintendent is competent. At the new asylum for chronic insane at Medfield, special provision will be made for epileptics, and the greater proportion of those now in lunatic hospitals will probably be transferred there. With an institution at Baldwinville to treat *sane* epileptics of all ages, and departments in the asylums to care for *insane* epileptics, the provision for those unfortunates will be ample in Massachusetts.

There is, however, one serious difficulty standing in the way; and until it is modified, many epileptics as well as large numbers of the insane will not receive continuous rational treatment. I refer to the settlement laws. The support of those defective ones, whose lives are prolonged by our philanthropy, is a heavy burden upon towns and cities. One of two things should be done; an institution should be so managed that the expense to towns for the treatment of their pauper epileptics there will not exceed the cost of their detention in almshouses, or the Commonwealth should assume the entire care and expense of all such epileptics, making them wards of the State, as it ought to do in the case of the entire number of the indigent insane. There are to-day two hundred and thirty-five epileptics in our distinctive State institutions, not including the prisons and School for Feeble-Minded, those in the insane asylums representing about five per cent. of the whole number of inmates. There are no epileptics in the State reform schools (the Lyman School for Boys at Westborough and the Industrial School for Girls at Lancaster), and only two in the State Primary School at Monson. There are but twenty-three epileptics at Tewksbury, and twenty at the State Farm in Bridgewater.

DR. T. W. RUSSELL, of Winchendon, said: I can hardly hope to add anything of value after the remarks of Drs. Baker and Flood. I may, however, still further emphasize the need of such a hospital for chronic epileptics as is now established at Baldwinville. Some years ago, while making a professional call at a town almshouse, I saw an epileptic girl go to the swill pail in the kitchen and help herself to a quantity of the filthy stuff. On my vigorous protest, the matron, an especially kindly woman, said that it was with great difficulty that she could prevent a frequent repetition of this act. This girl was not allowed to have any treatment for her epilepsy for twenty-five years lest it might be "experimentation."

For some years I frequently saw an epileptic girl in a large family of children. It was an everyday affair for her to have a convulsion in their presence. Her mother would drag her into a little den opening from the kitchen, throw her on a lounge, and leave her there to fight out the attack as best she could. The effect on these young minds must have been dreadful. As she grew older, the mothers of the boys in the neighborhood found it necessary to have her removed from home to a place of restraint — of course, the town poor-farm. Here she soon received the devoted attention of a member of the family, from which, however, I succeeded in rescuing her without material damage.

There are three epileptic children in my own village, two of whom are a perfect terror to the neighbors. No one of them can by any possibility receive any such care as he needs. One lives with an idiotic brother, and an insane mother, by the side of the railroad track.

This hospital for epileptics can do a great work for the profession. Within its walls can be gathered a great mass of statistics regarding the disease. Therapeutics should be a great feature of its work, checked by most conscientious clinical records before and after the trial. Determinations of the exact value of different drugs and combinations in treatment can be made: for instance, the value of chloral in combination with the bromides, or the concomitant use of belladonna, or the value of cathartics as a method of treatment, or this last combination of antipyrine and the bromides, as proposed by Dr. Wood, of Philadelphia.

There is no end to the good work which such an institution can do; and I am happy to say that the Hospital-Cottages for epileptic children at Baldwinville has now the facilities for doing the work, and are determined to improve their opportunities.

DR. WALTER E. FERNALD, Superintendent of the Massachusetts School for the Feeble-Minded, at South Boston, said: Epileptics have not been admitted to the School for the Feeble-Minded to the exclusion of improvable non-epileptic children. A certain proportion of our children develop epilepsy after admission; and in their cases the fact that the child is epileptic is concealed until after admission. Since the spring of 1890, when the first of the new buildings at Waldham was completed and occupied, no epileptic child has been refused admission. For the year ending September 30, 1890, in a total of 130 admissions, 57 were epileptic. These cases are seldom discharged, and tend to accumulate. The school, with its present facilities, can easily care for epileptic children, but not for adults. Sometimes these epileptics are transferred to town poor-houses for the sake of saving a few cents a week.

REV. R. KIDNER, of Boston, said: It seems to be the unanimous opinion of those qualified to pronounce on this subject, that epileptics, both the very poor, and those of moderate means, are not, and cannot be under existing conditions, properly cared for in this State. The question then arises, What can be done about it? To that question, there is but one answer, — public opinion must be aroused, which will lead to the right solution of the problem. It is scarcely fifty years ago since Miss Dorothea Dix gave her life to the service of the insane, and went everywhere, ferreting out their woes and sufferings, and demanding their redress. We must find a Dorothea Dix for the epileptic. We have been told with what inhumanity they are treated by town and city authorities. The public must learn the condition of things, and a devoted woman could make it known more effectively than any man.

In this, as in other benevolent work, private beneficence might perhaps precede public action; and I should favor the immediate establishment of a small hospital near Boston, in which a beginning could be made, and experience gained. This would become the nucleus of a State institution, or at least serve as a suggestion to the State. I believe that the necessary funds could be secured to make this beginning. Our charitable people give very freely to hospitals, and respond liberally to appeals for projects which alleviate human suffering. Many calls are made upon the public generosity, but there is no fear that those calls will exceed the ability and willingness to give.

DR. G. F. JELLY said, that, as he sees patients in the line of his practice, there are no more pitiful and distressing cases than those afflicted with epilepsy. Until the establishment in Baldwinville was open, there was no provision in the State of Massachusetts for epileptic children. Even at Baldwinville, as yet there is accommodation only for a certain number of this class of cases. In the new State institution at Waltham, there will be some available accommodation for feeble-minded patients with epilepsy, and this will relieve to some extent the over-crowding of those institutions into which epileptics are at present admitted, or where the disease has been developed among those who were not epileptic when admitted.

There are both sane and insane epileptics. In many cases of either variety, the post-epileptic condition is the most dangerous; and at present we are absolutely unable to take care of those cases. An instance recently occurred in which a passenger upon a railroad shot the conductor who asked him for his ticket. In the court the prisoner was judged to be an irresponsible epileptic at the time of the commission of the murder. That man is sane, and is at large at the present time, and liable to repeat his former act at any moment. Insane epileptics can be sent to an asylum or to the almshouse; but they do not belong in an insane asylum, and they are not the recipients of care or treatment in the almshouses. They should never, under any circumstances, be condemned to the almshouses, though they can be admitted there. There is no place for the reception of non-insane cases, either for restraint or treatment. In some respects the insane epileptic is better off than his afflicted brother who is perfectly sane.

A rich man can build a proper house, and can secure proper care for an insane person; but even this is not desirable, as an insane person is usually better off, both in relation to others and to himself, when

removed from his family. Under existing conditions a separate department in some insane asylum would probably be the most practicable arrangement; but this should be a separate and independent department, in no way connected with the insane wards of the asylum. In such a place much could be done for the care of these unhappy patients, and some relief afforded to the existing institutions in which epileptics are now found, where they form an obstacle to the proper administration of the institution, and affect unfavorably the other inmates of these institutions.

DR. MORRIS PRINCE said: It is a great injustice to send epileptic patients to pauper institutions, on account of their helplessness in earning a livelihood. Epileptics are not helpless because they refuse to work, or are unwilling to work, but because they are unable to work. Such a person is under the constant apprehension of an impending recurrence of a frightful disease; and after the establishment of the malady, he is unfitted both in body and in mind for labor or responsible occupation. He should be regarded as a sick person, and should be sent to some place where he can be treated as a sick person is treated, that is, in accordance with the requirements of his individual needs. Two cases of epilepsy were recently brought to the station-house by the police, charged with intoxication; and both were condemned to Deer Island to work out a sentence imposed by the court for drunkenness. Another man who had consulted me in relation to the disease was attacked upon the street soon after leaving me. He had experienced the premonitory aura, and had often been told that a moderate amount of whiskey would prevent the full attack. He took the remedy, and not feeling the relief which he sought, took some more; then the attack was developed, and he was found prostrate and helpless in the street, and was brought to the police-station and incarcerated as a common drunkard. He was brought to court; and only after the most vigorous efforts on the part of counsel and physician, could the court be induced to relieve the patient from the charge of which he had been accused. The patient has become melancholy, is afraid to appear out of his house, owing to the constant apprehension of further attacks of the disease; and his case is truly deplorable. Unfortunately there is no place where such a patient can be taken in and cared for, and this class of sufferers are left practically without aid or assistance in their great need.

DR. MCCOLLUM stated that the arrest of an epileptic by the police, upon the charge of intemperance, is not uncommon, as his experience in the care and disposition of these unfortunate cases amply proves. The epileptic patient may be suddenly prostrated upon the street, and in the violence of the epileptic discharge may be entirely uncontrollable, and may impress the ordinary observer with the idea of intoxication. In the post-epileptic state he may for a certain time be quite unconscious of his deeds, and may then commit any misdemeanor or any crime, of which he has absolutely no knowledge. In one case of epilepsy known to the speaker, a most orderly citizen has been arrested on the charge of drunkenness five times in six months. The patient is in the intervals apparently well and sane; but at the times of the epileptic attack, he is for a certain period, oblivious of his acts and surroundings, and at such time he becomes the subject of arrest. Additional laws are needed by which physicians may be empowered to send epileptics to proper institutions for

care and observation, and thus spare them the double cruelty of constant liability to attacks in public places where they may do harm to themselves or others, while we are not able to afford them either care or protection.

Dr. A. N. BLODGETT said that the present discussion had served to present an array of facts in relation to the condition of persons afflicted with epilepsy, which appeal to the sympathy and charity of both the medical profession and the public. It would be very unfortunate if this important subject were not further pressed; and for that purpose he moved the appointment of a committee of three by the Chairman, to present the action of this meeting before the members of the Massachusetts Medical Society, at the next annual meeting, and urge their active coöperation in the amelioration of the condition of persons suffering from epilepsy.

The motion was carried unanimously. The Chair appointed as that committee, Drs. W. N. Bullard, A. R. Moulton and G. F. Jelly.

The thanks of the Section were extended to those gentlemen, not members of the Section, who by their presence and assistance had contributed to the interest of the meeting.

## THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MEETING, November 8, 1890.

Dr. DRAPER reported

### A CASE OF TUBAL PREGNANCY, WITH RUPTURE AND FATAL HÆMORRHAGE AT AN EARLY STAGE.<sup>1</sup>

Dr. DAVENPORT said that tubal pregnancy was very unusual in a woman of this age, and in one who had not been pregnant before. Such accidents generally occurred in those who had previously borne children at an interval of several years following the last pregnancy. Hence the diagnosis in this case was rendered unusually difficult.

Dr. DOE spoke of the advice given by Thomas to wait until the patient recovered from collapse before operating. In six of the latter's cases not operated on, only one recovered, while in eight cases where the operation was performed, four recovered and four died.

Dr. F. B. HARRINGTON said that in cases, where he afterwards found on laparotomy large quantities of blood in the abdominal cavity, he was surprised to find no evidence of this by palpation and percussion, and he spoke especially of a case of severe gun-shot wound of the abdomen.

Dr. DRAPER said that in the case he reported there was no evidence from percussion of the large amount of blood in the abdomen.

Dr. HOMANS said that the symptoms in the case reported showed plainly that the patient was suffering from severe hemorrhage and that this hemorrhage must be in the abdominal cavity, as there was nothing pointing to hemorrhage in the chest or head. Hence the only proper thing to do would have been to open the abdomen and tie the bleeding point. It might have done good, and certainly could have done no harm.

Dr. M. H. RICHARDSON spoke of a case where there was sudden abdominal pain, and a subnormal

temperature from collapse, where he opened the abdomen, found a large amount of blood from a ruptured tubal pregnancy, tied the tube, and the woman recovered. He certainly should not consider it proper to wait till recovery from collapse, as that very often goes on to death.

Dr. E. W. CUSHING said that rupture in tubal pregnancy might occur either within the folds of the broad ligament in which case a hæmatocele will form, and the patient may rally from the collapse, or secondly into the general abdominal cavity when the collapse is generally fatal. He referred to the cases reported years ago by Dr. Jackson, where death was generally inevitable.

Dr. Cushing advocated opening the abdomen in all cases of abdominal hemorrhage, a small opening being sufficient to establish the diagnosis.

In Philadelphia several cases of laparotomy for ruptured tubal pregnancy were reported almost every month, whereas very few are reported from Boston, and he did not believe this difference was due to any difference in the constitution of the women in the two places.

The statistics of Thomas, that Dr. Doe referred to, were, he thought, old, and not to be compared with recent ones of Lawson Tait.

Dr. HOMANS reported

### TWO CASES OF LAPAROTOMY FOR INTRA-ABDOMINAL HÆMORRHAGE.<sup>2</sup>

Dr. BOARDMAN doubted the possibility of making the diagnosis in cases of tubal pregnancy till the patient was well-advanced in pregnancy, as even in normal pregnancy it was difficult to make the diagnosis before the eighth week; and he raised the question as to what should be done in cases of extra-uterine pregnancy before hemorrhage had taken place.

Dr. M. H. RICHARDSON said that in all the cases reported to-night with the very severe and marked symptoms, immediate laparotomy he believed to be the only proper course to take.

Dr. E. W. CUSHING said, in answer to Dr. Boardman, that it was at the present time a burning question whether to use electricity or resort to the knife in cases of extra-uterine pregnancy where rupture had not taken place. Electricity undoubtedly did good in some cases, but there is no question that some are lost in this way, fatal hemorrhage taking place in the intervals of treatment. He believed that at the present time the consensus of surgical opinion was in favor of immediate removal of the tube as soon as the diagnosis of extra-uterine pregnancy is made. If we delay we expose the woman to the risk of sudden and fatal hemorrhage. The puncture of the cyst by galvanocautery and the injection of morphine were methods now discarded, and he believed that to kill a child when large by electricity and to leave it to be absorbed in the abdominal cavity was opposed to modern ideas.

Dr. DOE said that Dr. Thomas up to the time he made his report, had had thirty-three cases, in twelve of which he used the electric current, and all recovered.

Dr. HOMANS reported the case of a woman, aged thirty-five, he had seen in October, who had been confined to her bed from May until September. At this time she had severe pain and the movements of the fetus suddenly ceased. The temperature previously

<sup>1</sup> See page 28 of the Journal.

<sup>2</sup> See page 27 of the Journal.

elevated, at times to 103°, became normal, and she has since felt entirely well. On examination he felt a five months' fetus between the uterus and rectum, and he decided to do nothing at present.

Dr. BLAKE suggested the inevitable dangers of supuration and fistula, and asked why the fetus should not be at once removed.

Dr. HOMANS remarked that in a very small number of cases, some twelve or fifteen only are recorded, the fetus was changed to a lithopædion.

Dr. M. H. RICHARDSON said that there was danger of hæmorrhage in separating the placenta if one operated early, and that it was better to wait until fatty degeneration of this organ had taken place. He had once operated at eleven months, and was able to separate easily the placenta from the intestines, whereas if he had operated earlier, a serious hæmorrhage might have occurred; hence he considered Dr. Homans's course the wise one.

Dr. E. W. CUSHING reported, by invitation,

#### A CASE OF EXTRA-UTERINE PREGNANCY; OPERATION AT THE NINTH MONTH; RECOVERY.<sup>3</sup>

Dr. GREEN suggested that as the fetus showed that it was fully a month beyond the period of viability, an earlier operation might have saved its life as well as the mother's.

Dr. CUSHING said that at that time he was not at all sure the case was really one of extra-uterine gestation, and an operation at that time would have been rendered very serious by reason of hæmorrhage, if he attempted to separate the placenta, or of sepsis if, as has been advocated, the placenta were left in and removed later.

Dr. WHITNEY asked Dr. Cushing whether the placenta could be formed on a serous surface, or whether it was always formed in the tube, that is, on a mucous surface.

Dr. CUSHING replied that according to Tait all extra-uterine pregnancies were originally tubal. The placenta may afterwards attach itself to a serous surface, but he does not believe it could arise from that.

Dr. Cushing read brief notes from an article by Dr. W. A. FIDES on the subject of Lithopædia. The author had collected twelve cases, from medical literature, which he believed were the only ones known.

Dr. WHITELY remarked that there were two specimens of Lithopædia in the Warren Anatomical Museum, which, considering the rarity of the cases, was a large number.

Dr. F. B. HARRINGTON showed a simple and aseptic method of carrying needles in the pocket ready for use. The needles were kept in absolute alcohol in small bottles in a pocket case.

THE PURSUIT OF KOCH'S TREATMENT. — The Royal College of Physicians of Edinburgh have passed the following resolution: — "That this College records its regret at the publicity which has recently been given to certain initial experiments upon Koch's system of treatment of tuberculosis, as injurious to the best interests of the public and the profession." The Secretary was directed to transmit this resolution, not only to the medical journals, but also to the lay press. Accordingly, it appeared in the Edinburgh morning and evening newspapers.

## Communications on Koch's Method.

### KOCH'S REMEDY IN BOSTON.

BY H. H. A. BEACH, M.D.,  
Visiting Surgeon, Massachusetts General Hospital.

THE first consignment for Boston from Dr. Libbertz of the preparation which is now exciting the interest of the whole medical world, reached this city on the 25th day of December. My term of regular service not beginning until March 1st, I immediately tendered the application of it to my colleagues now serving, Drs. Porter and Warren, of the Surgical, and Drs. Tarbell and F. C. Shattuck, of the Medical Staff of the Massachusetts General Hospital. In return, they very courteously offered me patients who were desirous of having the remedy applied.

A reasonable recognition of the unusual interest felt here in the success of the great discovery, required that every care and precaution should be observed in its dilution and administration, to ensure accuracy of measurement, an aseptic condition of the remedy from the time of its dilution to its administration, and a judicious selection of cases and doses in its employment.

First of all, two separate translations from the German, of the directions accompanying the remedy, were kindly undertaken by Professor W. T. Sedgwick, State Bacteriologist, and Dr. Otis K. Newell of the hospital staff. These were carefully compared and revised to control any question of accuracy. (Copy annexed.)

Secondly, the dilution of the remedy in a large general hospital, where every facility exists for the contamination of any fluid, appeared to offer disadvantages not associated with a carefully conducted division in a biological laboratory, where unusual and special preparations could be matured and carried out with special reference to the sterilization of the dilutions. That portion of the work was entrusted to Professor Sedgwick, Director of the Biological Laboratory of the Massachusetts Institute of Technology, and Mr. William C. Durkee, Chairman of the Educational Committee of the College of Pharmacy. They have kindly furnished an account of the various processes employed by them in its preparation.

I decided to inject at first, the minimum dose advised by Professor Koch, believing that the amount of reaction and subsequent symptoms would furnish the safest indication for future inoculations. Bearing in mind the recent testimony of Dr. David Orr Edison, now in Berlin, (see following quotation). I did not employ the so-called Koch syringe, but, instead, one devised by Mr. Durkee, and described later. Dr. Edison says: "The Koch hypodermic syringes are not being used in the hospitals I have visited, as they are not considered capable of perfect sterilization. The ordinary hypodermic syringe is in vogue."

The patients selected for inoculation were all carefully examined by five members of the visiting staff, who were united in opinion upon the accuracy of diagnosis in the distinctly tuberculous cases, and upon the expediency of employing the remedy as a diagnostic test in the doubtful cases. The skin of the back, in the vicinity of the inoculation, was carefully sterilized as for an operation.

Inoculations were begun, January 1st, upon a case of lupus, of which there had been some doubt as to the diagnosis. A characteristic reaction followed from a dose of one-half of a milligramme. The temperature,

<sup>3</sup> See page 39 of this Journal.

reaching 104° F. when at the maximum, was followed by the usual fall to the normal point. The other cases, eight in number, of which one was a lupus, two with tuberculous elbows, one tuberculous tongue, and four cases of phthisis, were divided with Dr. Harold C. Ernst, Instructor in Bacteriology of the Harvard Medical School, who had arrived from Berlin during the preparations described, as already announced in the JOURNAL.

So far, the cases have progressed successfully and without serious discomfort, owing, I believe, to the most absolute loyalty to the principles contained in the specifications, as taught and practised by Professor Koch. The interesting details, with temperature charts and results, are to be drawn up carefully for future publication, with the assistance of Dr. A. K. Stone.

The following is a brief description of the methods adopted by Mr. Durkee and Professor Sedgwick for dilution and sterilization: A new culture-room, kindly offered by Professor Sedgwick, was selected as the best place in which to make the dilutions and divisions into small portions for distribution. This room was thoroughly washed with solution of mercuric chloride immediately before beginning the work, and all glassware or utensils sterilized.

A pipette of extreme fineness was made, and accurately calibrated to contain one-tenth of a cubic centimetre. As the calibrated portion was about five inches long, the measurement could be read with great minuteness. The remedy is drawn into the pipette by a rubber cot or cap such as is used in the hypodermic syringe, described later. By this, one-tenth of a cubic centimetre of the original remedy is transferred to a sterilized weighing-bottle of ten cubic centimetres' capacity, and the interior of the pipette washed thoroughly by repeatedly drawing up distilled water, ammonia (free and sterilized), and discharging it into the weighing-bottle, which is stoppered and agitated several times to insure a thorough solution; the flask ultimately being completely filled with the mixture of the distilled water and the remedy, makes a one per cent. solution. From the weighing-bottle a previously sterilized pipette, with a long hypodermic needle tube is filled. With this pipette little glass flasks or capsules with stems about two inches long and holding about one-fifth and one cubic centimetre respectively, are filled. The little flasks are hermetically sealed by fusing the stems with a fine blowpipe flame while the bulbs are protected from heat by being held between the fingers. The portion of stem left is about one inch long, making the bulbs look as in the cut. Before filling, the bulbs are carefully washed with a two per cent. solution of hydrochloric acid, and then emptied and repeatedly filled with distilled water, dried and sterilized.

After the little flasks are filled, they are sterilized in a steam sterilizer for half an hour, which process is twice repeated on the following days: The bulbs are so strong as to show no special tendency to burst or break, and the heating affords an easy test of the sealing. A little more of the solution is put in the smaller capsule than is needed for a two-milligramme dose, so as to give a little latitude for accidental loss. The stems of the capsules are slightly cut near the base with a fine dental file, allowing them to be easily broken without splintering the glass.

To introduce the syringe needle into the orifice made in the bulb by removing the stem, draw up a portion or all the contents, read the scale, perforate the skin, inject the desired amount, and withdraw, is the work of a moment.

Although the use of the glass capsule or pearls for preserving a small quantity of hypodermic solution is new, and suggested by Mr. William C. Durkee, it is believed that, for portability, convenience, perfect protection from bacteria, there is nothing which approaches it in desirability. Once thoroughly sterilized, solutions may be preserved indefinitely; are instantly available in emergencies; they do not require a dish or spoon, heat or water; never trouble about dissolving, or clogging the needle.

#### AN IMPROVED FORM OF HYPODERMIC SYRINGE.

Instead of the ordinary Koch syringe of large calibre, with bulb and stopcock, Mr. Durkee invented for the first injection at the Massachusetts General Hos-

pital a simpler syringe, composed of only three, or at most four parts. It may be described as follows: A graduated glass thermometer tube about six inches long, of narrow bore, with the usual hypodermic needle attached by a cap fitting with a taper joint upon one end of the tube; a heavy rubber cot,

Durkee Syringe, with Bulb.

Koch Syringe.

about two inches long, fitting closely over the other end. This cot can be moved up and down the tube by slightly rotating it upon the glass, increasing or diminishing the pressure within the tube, and thus sucking up or pressing out the fluid. Instead of a rubber cot, a glass cap larger than the syringe tube may be used, and a piece of rubber tubing used to connect them. In this form, the cap and tubing together move up and down upon the tube.

This novel hypodermic syringe was invented by Mr. Durkee, December 27th; was tested by the writer,

December 29th, and found to work perfectly. Several days later it was learned that a syringe of four pieces had been used in Germany, similar to the one last described, with this important exception—the capillary tube was not used, neither has it been used by any one, as far as I am aware, for the accurate administration of medicines hypodermically, until Mr. Durkee suggested it. Working independently, he had developed almost exactly the same idea for moving the liquid, and made an instrument almost precisely the same, with this exception, that the small inside calibre of the tube allows far greater accuracy of reading.

The advantages of the pistonless syringe are obvious. It is far more easily cleaned and kept sterile; is more convenient, portable and accurate. Another improvement consists in keeping the syringe in a straight glass tube like a test-tube, but stronger, filled with absolute alcohol; thus keeping it sterile, and thus, with the aid of the glass capsules, avoiding all danger of abscesses.

It is advised that, after the needle has been plunged into the dilution for injection, it should be dipped into absolute alcohol to remove any possibility of a contamination of the fluid injected along the course of the needle track.

#### DIRECTIONS FOR USING KOCH'S REMEDY FOR TUBERCULOSIS.<sup>1</sup>

THE remedy will keep for a long time; the dilutions, on the other hand, spoil easily and then become turbid. Samples which have become turbid must not be used. In order to protect the dilutions from spoiling, these must be boiled after every opening of the vessel. This latter precaution, however, is unnecessary if one-half per cent. (0.5%) carbolic acid solution has been used for making the dilution.

The dilutions are prepared as follows: a ten per cent. solution is first made by adding to one cubic centimetre of the remedy, nine cubic centimetres of distilled water, or a one-half per cent. solution of carbolic acid. In the same way a one per cent. solution is prepared from the ten per cent. In this way those dilutions are made which are necessary for the treatment of adults. For children it is expedient to use a still greater dilution; for example, a solution containing two-tenths (0.2) of one per cent. Since the weak solutions lose their effectiveness after long keeping, it is advisable to make them fresh as often as possible.

It distilled water is used for the solutions, these should be kept in sterilized test-tubes, plugged with cotton-wool, since in these they can most conveniently be boiled over a gas or alcohol lamp.

The remedy is injected subcutaneously, and experience has shown the best point of injection to be the skin, between the shoulder-blades, or in the lumbar region. The injections are done best by means of a sterilized Koch syringe, of one cubic centimetre capacity, graduated to one-tenth of a cubic centimetre. For sterilization, it suffices to wash out the syringe and needle with absolute alcohol. Abscesses are thus surely avoided. If it is desired to use an ordinary Pravaz syringe, then the attempt should be made to sterilize this beforehand, as far as possible, by repeatedly drawing up absolute alcohol; but abscesses are in this case not so certainly avoided.

The course of the temperature must be followed both before the beginning of the injections, and also during them. It is therefore necessary to begin, at least one day before the first injection, with observation of the temperature every three hours, and to take care that this is continued during the whole treatment.

The injections are recommended to be made in the early hours of the forenoon that the effects of them, especially upon the temperature, which only appear after several hours, may be observed on the same day.

For the first injection in phthisical patients, one thousandth or two thousandths (.001–.002) of a cubic centimetre of the undiluted remedy are employed, and therefore with the one per cent. dilution, one to two divisions on the syringe are injected. On the following days the treatment proceeds cautiously, either by repeating the same dose, in case the fever rises above 38.5° (101.3° F.), or possibly stopping it altogether; or, if no fever, or only a little fever, occurs, by increasing the dose, by one thousandth to two thousandths of a cubic centimetre of the original remedy. When the dose of one hundredth of a cubic centimetre has been reached, then, with careful attention to the temperatures, the dose can be increased by one hundredth or two hundredths of a cubic centimetre; when a daily dose of a tenth of a cubic centimetre has been reached, then, as a rule, it need not be further increased.

Only exceptionally will it be found necessary to reach two-tenths of a cubic centimetre or more. The injections are then continued with interruptions of one or more days, until the symptoms of disease have disappeared. If we are dealing with a lupus which is not very extensive, we can with adults, employ one-hundredth of a cubic centimetre of the undiluted remedy at once, and repeat it when necessary.

The same holds true for tuberculosis of the bones, joints and glands.

No guarantee can be given for the proper composition of the remedy, unless it has been obtained directly from the undersigned, Dr. A. Libbertz, Berlin.

#### DIRECTIONS BY KOCH HIMSELF.<sup>2</sup>

The remedy can be kept in its original form without special precautions; for use, however, the liquid must be diluted more or less, and the dilutions, when prepared with distilled water, are decomposable.

Bacteria develop in them very soon; they become turbid, and are then no longer to be used. In order to prevent this, the dilutions must be sterilized by heat and preserved under cotton-wool; or, what is more convenient, be prepared with one-half per cent solution of carbolic acid. By frequent heating, as well as by mixing with carbolic acid, however, the action appears to be influenced after some time, especially in greatly diluted solutions, and I have, therefore, always used solutions prepared as freshly as possible. The remedy has no effect through the stomach. In order to obtain satisfactory results, it must be injected subcutaneously.

#### IEWS AND RESULTS FROM VARIOUS SOURCES.

In a clinical lecture PROFESSOR CORNELI<sup>3</sup> said that the results of his observations tended to show that the renal complications caused by Koch's fluid are merely

<sup>1</sup> *Seminare Medicinæ*, December 17th.

<sup>2</sup> Extracted from his paper of November 13th in the *Deutsche Med. Wochenschrift*.

<sup>3</sup> A translation of the *Unternehmensanweisung* of Dr. A. Libbertz, sent by him with the material.

temporary, and that, even when the kidneys are diseased, the treatment is not absolutely contraindicated, although it must be used with extreme care. With regard to the reaction, he pointed out that it is a mistake to suppose that after the injection the temperature simply rises to a greater or less height, and then falls to the normal point. In some cases a quotidian fever was noticeable, lasting two or three days. These irregularities in the course of the reaction should be borne in mind, and sufficient time should be allowed between the injections to avoid any danger of cumulative action. He expressed the opinion that the amount of oxyhemoglobin gives a fair measure of the effect of the injections, and adds that it cannot be doubted that where it is diminished the patient's general condition becomes worse, and it may be concluded that the injections are doing harm. While not venturing as yet to pronounce a final judgment on the value of the method, Professor Cornil says that with proper care there is little risk of doing any harm to patients by the injections; that in certain forms of tuberculosis, notably in lupus, "appreciable improvement" is produced.

ROSENBAUGH<sup>2</sup> points out that if the injection is made at a time when there is a natural tendency towards decrease of temperature the fever of reaction does not run so high as when the usual tendency to rise coincides with the effect of the injection. In some cases of undoubted tuberculosis no reaction followed the injection of the ordinary doses.

SAUNDEY, SIMON, and BARLING<sup>3</sup> consider the weak point of the treatment to lie in the fact that in many cases of tuberculosis of internal organs surgical interference for the removal of the necrosed tubercle with its still living bacilli is impossible.

Among their conclusions they notice that the reaction varies greatly in its intensity, and undoubtedly bears some relation to the dose employed, cases of undoubted tuberculosis having, in several instances, failed to react to 0.001, 0.002, 0.003, and even 0.005 cc. of the fluid. There is, however, no absolute relation between the dose and reaction, some cases having reacted violently to the smallest of these doses. This difference does not depend upon the evident extent of the tubercular disease present, or on the organ affected, but upon individual susceptibility, which has not been at present defined. It is, therefore, very important to commence with small doses. Before commencing treatment in cases of external tuberculosis, evidences of internal tuberculosis should be carefully sought for. The existence of hæmoptysis does not contraindicate the employment of the treatment, but we would urge caution under such circumstances. No reaction follows after the continued employment of the same dose, but this tolerance is not acquired after a uniform number of injections.

THIBERGE<sup>4</sup> gives an account of his personal observations of effects of Koch's treatment on lupus during a visit to Berlin. In all the patients whom he examined without exception, even in those who had been the first subjects of the experiments, and who, therefore, had been under treatment for a period of nearly two months, he was able on minute examination to discover lupus nodules. In view of these facts he thinks

himself justified in asserting that there has been as yet not a single instance of even apparent cure of lupus by Koch's treatment. He acknowledges, however, that the injections have a marvellous rapidity of action and a cicatrizing influence on extensive and rebellious lupus ulcerations.

According to HASLAND<sup>5</sup> the destructive action of the fluid is exerted only on the most superficial tuberculous tissue, and does not reach the deeper nodules. His conclusion is that Koch's method, whilst it is an auxiliary remedy of the highest importance, must be followed by surgical treatment (galvano-cautery, electrolysis, scraping, etc.).

KROMEYER<sup>6</sup> is of opinion that by combination with the metabolic products of the tubercles some new chemical substance is formed in the vicinity of the latter, which sets up inflammation around them, and leads to their breaking down into pus.

DR. FRANK FREMONT SMITH,<sup>7</sup> who has been studying Koch's methods in Berlin, says that it is recognized that tissues affected by another than the tubercle bacillus may be susceptible to Koch's fluid. There have been reported cases of leprosy, and one of rodent ulcer, in both of which good reactions and improvement followed exhibition of Koch's lymph. Unsuspected tuberculous areas, brought out by the selective power of the lymph, may produce alarming or dangerous symptoms.

Henoch has in the past week denied the advisability of making injections in cases of tubercular meningitis, deaths having occurred during reaction. In the autopsy of a case of Henoch, Virchow stated that the amount of blood in the brain exceeded any previous experience.

Krause warns of necessity of laryngeal examination before injection, lest sudden swelling or rapid cellular infiltration of a susceptible mucous membrane may produce complete closure. Two cases in the wards of Senator, two in those of Cornet, and one in Gerhardt's, wear tracheotomy tubes in testimony.

An adult patient was observed in Gerhardt's wards, December 8th, with infiltration of the left apex and bacilli in sputum. After the first injection the right apex, before normal to percussion, presented marked dullness down to the second rib. This passed off with decline of reactive fever. It occurred during the reaction of the two succeeding treatments, ceased with the fourth, and has not returned. In the same wards an adult female is shown, who, after her second injection (one centigramme) suddenly developed distressing dyspnoea; absolute dullness over the lower angle of the right scapula as large as the palm, with crepitant râles.

Kast, of Hamburg, reports a case of a female adult, with extensive lung tuberculosis, who was treated with gradually increasing doses, which were well endured until an injection of fifteen milligrammes was reached, when suddenly, during reaction, she fell into collapse.

Cases of sudden heart failure and death have occurred. The best authorities here do not consider the remedy cumulative. Children frequently suffer considerable diarrhoea during the early treatment. This usually corrects itself with cautious dieting, and the system becomes tolerant.

## KOCH'S REMEDY IN LARYNGEAL TUBERCULOSIS.

MR. LENNOX BROWNE<sup>1</sup> writes from Berlin that the following are a few of the more obvious points which may so far be accepted as decided: Laryngeal tuberculosis is a far more frequent association of pulmonary disease than is generally admitted; and, *vice versa*, the throat is but rarely affected without associated pulmonary disease. This association does not take place as an accidental sequel, such as from the infection of the larynx or pharynx by pulmonary sputa, but it may exist, and lie dormant, long before it is actively evident. The laryngeal complications of pulmonary tuberculosis are rarely, if ever, of a simple catarrhal nature, but are essentially of the same specific character as the disease in the lungs. The frequent association of lupus of the nose with similar involvement of the pharynx and larynx is strengthened by the development of the disease in these latter situations in patients under treatment for its manifestation in the former situation.

The most usual laryngeal evidences previously noted as early characteristics of tuberculous laryngitis — namely, bilateral swelling of the mucous folds and coverings of the arytenoid, and of the epiglottis — are just those which are observed to be developed under the Koch treatment. In like manner past experience is confirmed that unilateral swellings and unilateral ulcerations are less common than the bilateral, and that the lesions are more or less symmetrical. Under this treatment, ulcers representing necrotic changes may develop and may heal with an unexampled rapidity, and infiltration and quasi-new growths may become absorbed. Such a circumstance warrants us in supposing that similar changes take place in the lungs. In fact, some of the cases noted in the wards of Professor Gerhardt are quite convincing on this point. In a few cases only did he observe no improvement.

As to treatment, all will do well to commence with the minimum dose of a milligramme, or even less, as recently advised by von Ziemssen, in all laryngeal cases, and not only in those in which there is already infiltration, for in this treatment it is the unexpected which often happens, and no one can foretell the case in which there will be undue reactionary oedema, with stenosis in addition to the always to be observed hyperæmia. Wherever stenosis of high grade occurs, intubation is, *ceteris paribus*, preferable to tracheotomy.

In a few cases in which there has not been improvement, the treatment has been of great diagnostic value, and setting aside any other consideration, there cannot be the least doubt that the greatest credit will always redound to Koch for his discovery as a means of ascertaining, with scientific and absolute precision, the existence and extent of tuberculous disease at its earliest stage.

Finally, it should be remarked that, though there does not appear to be any marked difference in the reactionary fever that takes place as a result of this treatment when employed for laryngeal disease from what is observed in the course of other maladies under a like procedure, there are often to be observed, as exceptions to the rule that change and fever go *pari passu*, actual physical alterations of the greatest importance taking place in the diseased structures when the reactionary fever is almost nil, and *vice versa*.

The former exception of these two has so far happened to be the most frequent.

DEATH AFTER INJECTION OF KOCH'S FLUID:  
AUTOPSY.

JARISCH<sup>1</sup> records the history of a case of lupus vulgaris in which death occurred thirty-six hours after the injection of two milligrammes of Koch's fluid. The patient was a girl aged seventeen, suffering from a very extensive lupus exulcerans of the face, by which much of the nose and face had been destroyed and the mouth so contracted that it had been impossible to examine the oral cavity or to make a laryngoscopic examination. The patient had been under treatment in the hospital at the Innsbruck University for eighteen months, and her general health had been fairly good. Physical examination of the chest and abdomen did not disclose any morbid condition therein.

The temperature on the day before the injection was 36.9° and 37.5° C. respectively. On December, 3d, at 9 A. M., two milligrammes of Koch's fluid were injected; the same solution had been used on three other patients. At 2.30 P. M. there was a rigor, combined with local swelling of the lupoid parts; the temperature rose at 3.30 P. M. to 39.9° C., and at 12 P. M. to 41.1° C., pulse 160. Vomiting of bilious matter occurred also in the same afternoon, and the patient became very drowsy. On December 4th the temperature reached 41.5° at 3 P. M., and did not fall under 40° C. The symptoms of collapse remained the whole day, and, though restoratives were freely used, the patient died at 9 P. M. of the same day.

Twelve hours later the post-mortem examination was made by Professor Pommer of Innsbruck. There were found reactive changes in the neighborhood of the lupus and in the lymphatic glands, which will be examined microscopically. In different parts of the large intestines (caecum, colon), in which were old cicatrices, lymphoid nodules, surrounded by hyperæmic rings, were observed. In both lungs numerous disseminated pneumonic foci of recent origin were found, accompanied by extreme pulmonary oedema; there was very marked oedema of the brain and spinal cord, an acute swelling of the spleen, and parenchymatous intumescence of less degree of the liver and of the kidneys. Capillary hæmorrhages were found in the pulmonary pleura, in the parietal layer of the pericardium, in the thymus gland, and in some parts of the spinal cord. All these changes had the appearance of recent date, while there were the following chronic lesions: Bronchitis with slight bronchiectasis, induration of the apices of the lungs without any sign of reaction, slight mitral stenosis with hypertrophy of the right heart, and hæmorrhagic pachymeningitis. There was neither stenosis or oedema of the larynx.

It appears that death was caused by the disseminated lobular pneumonia and by the oedema of the brain, but with regard to the latter phenomenon, the presence of the old pachymeningitis must be taken into consideration as one of its principal causes. The case shows that even in otherwise apparently healthy persons affected with lupus vulgaris there may exist some incipient pathological changes which should induce physicians to make the injections only in patients whose life-history and bodily state are known by them to be above suspicion.

<sup>1</sup> Wiener klinische Wochenschrift, December 11, 1890.

## EFFECT OF KOCH'S FLUID ON THE BLOOD.

HÉNOCQUE<sup>1</sup> has made a series of spectroscopic examinations of the blood in twenty-two patients under treatment by injections of Koch's fluid with the following results: In thirteen the amount of oxyhæmoglobin was diminished, in three it was first diminished and afterwards increased, in three there was little or no change, and in three there was an increase from the first. The diminution was seldom observed before the second or third day, or even later, after the beginning of the treatment. It was observed in lupus as well as in pulmonary phthisis, and appeared to be in proportion to the number rather than to the strength of the injections. There seems to be no relation between the intensity of the reaction and the variations in the amount of oxyhæmoglobin.

FRAENKEL, KITASATO AND BEHRING.—The names of these three men have recently become prominent in connection with their experiments in conferring immunity against diphtheria. Professor Karl Fraenkel passed his final examination as a physician in 1885, was appointed assistant in the Hygienic Institute on its establishment, and soon became Koch's first assistant there. In 1887 he established himself as private lecturer in Berlin University. About a year ago he was appointed professor of hygiene at Königsberg. He became generally known in medical circles by the publication of his "Elements of Bacteriology," in 1886. The most important of Fraenkel's special investigations are those of bacterial poisons, which he made in common with Ludwig Brieger, and which led to the discovery of toxalbumin. Dr. Kitasato, a Japanese by birth, has lived in Germany for five years, and has occupied himself almost all the time with bacteriological studies in the Hygienic Institute at Berlin. The biology of the cholera bacillus has been the theme of many of his researches. He has also gone deeply into the study of the tetanus germs, and has now published the results of his investigations in his article on immunity. One of his chief discoveries is that of the musk fungus. Dr. Ernst Behring, who has shown, in conjunction with Dr. Kitasato, how immunity against diphtheria and tetanus is conferred on animals, is an army surgeon, and has been working as an assistant for about a year and a half past in the Hygienic Institute. Among his first studies after he became a surgeon ten years ago, was the manner in which antiseptic remedies for wounds, especially iodoform, act, and he made a special study of the symptoms of iodoform poisoning. He afterwards tested the antiseptic value of silver solutions, creoline, and other chemicals. Cadaverine, the etiology of anthrax, and the immunity of rats are also among the themes to which he has devoted special attention, but diphtheria has recently been his exclusive study.

THE BRADSHAW LECTURE on Modern Abdominal Surgery, was delivered at the Royal College of Surgeons of England, December 18, 1890, by Sir T. Spencer Wells, Bart., F.R.C.S.

## VARIABILITY AND VARIETIES OF THE TYPHOID BACILLUS.

In his now famous address before the International Medical Congress, at Berlin, in August last, Koch touched upon the difficulties involved in the determination with absolute certainty of the presence of the bacillus of typhoid fever in air, fæces, water, etc., as follows:

"A very characteristic example of the difficulty with which the determination of a (bacterial) species is surrounded is exhibited by the bacillus of typhoid fever. If this be found in the glands of the mesentery, in the spleen, or in the liver of a typhoid victim, there can be no question that we are dealing with the real typhoid bacilli since no other bacteria have hitherto been found in these regions which could be confounded with these.

"But when we are dealing with the determination of typhoid bacilli in the contents of the intestine, in soil, in water or in dust, the circumstances are very different. In such places there are found numerous bacilli similar to those of typhoid which only a very skilful bacteriologist, and even then not with absolute certainty, can distinguish from the typhoid bacillus, since unmistakable and constant characteristics of the latter are, as yet, wanting. The statements repeatedly made of late, that typhoid bacilli have been detected in soil, in water-supplies or in foods can, therefore, be accepted only with a reasonable doubt."

In view of these statements, and because of the immense practical importance of typhoid fever in its relations to the public health, it becomes imperative for us to revise our knowledge of the bacillus of typhoid fever.

Through the researches of Klebs, Eberth, Koch and especially of Gaffky and Chantemesse and Widal, so precise a knowledge of the characteristics of the typhoid bacillus was secured, that, the last-mentioned observers, in 1887, believed that it had at length become possible to identify certain bacilli found in water as genuine typhoid bacilli. Following in the same line, other observers have found similar bacteria in water-sewage and fæces, and, relying upon special characteristics,

<sup>1</sup> Rev. Gén. de Clin. et de Théor., December 17th.

have pronounced them to be the bacilli of typhoid fever. One by one, however, these diagnostic "characteristics" have been found to be not absolutely trustworthy.

According to a very recent paper by Babes,<sup>1</sup> there exist in many cases of intestinal disease, in the organs or the faeces of man and the lower animals, in water, etc., bacilli which exhibit all the special characteristics of the typhoid bacillus hitherto described and which yet must be regarded as different from it. Even the most careful studies of the typhoid bacillus still leave much to be desired. Babes questions or denies successively the diagnostic value of the morphological peculiarities laid down by Chantemesse and Widal; the vacuolation and granular peculiarities described by himself and Buchner; the staining peculiarities obtained by Gram's method; the diagnostic value of motility of the growth upon gelatine, agar, and blood serum; and even the long-trusted growth upon potato, already discarded by some, is rejected by Babes. He, confirming Pöhl, affirms that "many bacilli resemble the typhoid bacillus in their growth upon potato" instancing, for example, some from the intestine, from water, and from the bladder and other organs in certain diseases. In the same way Babes rejects the formation of acid (Petruscky); the power of resistance to carbolic acid, 1:100 (Chantemesse and Widal); the cilia-like appendages (Tödler); the negative indol reaction (Kitasato); and all other single peculiarities, as being not really diagnostic.

On the other hand, while denying that the special peculiarities laid down by Gafky, Chantemesse and Widal, and others taken singly are trustworthy, Babes insists that by taking all of these characteristics together, we nevertheless obtain, as a resultant, a very characteristic picture of the typhoid fever bacillus.

At the same time, the question naturally arises: Is there any variability in the typhoid bacillus itself and are there any variations from the main type? Babes, impressed by the immense practical importance of accurate diagnosis of the pathogenic bacillus of typhoid, has re-examined the whole subject. During his work which has extended over two years and has included more than 12,000 cultures, he has, in a very few cases, found, outside the bodies of typhoid victims—on one occasion in water—bacilli which exhibited all the characteristics of typhoid bacilli hitherto described; while, on the other hand, from a comparison of the bacilli found in twelve cases of typhoid, from the body of the victims, he has been led to recognize a number agreeing, indeed, with the "typical" typhoid bacillus, yet not identical with one another. Especially noteworthy is the fact that, in some of the typhoid victims besides the typical bacillus—in one old case, even without it—there occurred distinct varieties of it. These were carefully compared with the typical form and especially with the original Berlin cultures. Forms agreeing with one or more of these "atypical" varieties were, in three cases, found outside the body.

The typical form was never detected by Babes except in the bodies of typhoid victims. The question then arises, Are these "varieties" capable of producing typhoid fever? The question remains open, although Babes is inclined to answer it in the negative.

His apparently careful and exhaustive investigation emphasizes the statements of Koch, and shows the difficulties attending the detection of the typhoid bacillus in drinking water. It suggests, also, the possibility that there may be varieties of the typical form existing in nature, and more or less capable of pathogenesis. If this should eventually be established it would greatly assist in the explanation of those sporadic or so-called autochthonous cases which are often extremely difficult to account for upon the ordinary theory of infection from antecedent cases. It might even furnish a simple explanation of the variations in the clinical history of the fever itself.

#### THE TREATMENT OF DYSENTERY BY THE ADMINISTRATION OF A SATURATED SOLUTION OF EPSOM SALTS.

DR. LEAHY, of the Indian Medical Service, has advocated the treatment of acute dysentery by Epsom salts in pretty large doses; and he publishes in the *Lancet* his method of treatment: "Take a sufficient quantity of sulphate of magnesia to saturate seven fluid ounces of water, and to this saturated solution, add one ounce of dilute sulphuric acid. The dose is a tablespoonful every hour or two in a wineglassful of water till it operates."

He says that he has treated one hundred and three cases by this method with the greatest success. In the earlier stages of acute dysentery this saturated solution of Epsom salts acts like a charm; fever, if present, disappears; mucus and blood are wanting in the stools, which become copious, faeculent, and bilious; the tenesmus ceases; the patient's anxiety diminishes; the skin acts well, and sleep follows the administration of the first few doses.

In other instances, he has given a drachm of the saturated solution with ten drops of the dilute sulphuric acid every hour until the stools have become copious, faeculent, and free from blood and mucus. When the stools have become normal in color and appearance, and the patient only passes two or three in the twenty-four hours, an ordinary astringent mixture of acid with laudanum, or a pill containing opium is all that is necessary to complete the cure. It is, of course, imperative to diet the cases with great care.

The advantages of this treatment over the treatment by large doses of ipecacuanha may be summed up as follows: (1) It has no depressant action on the system; (2) It neither produces nausea nor vomiting; (3) It quiets and soothes the patient; (4) Its physiological action on the mucous membrane of the intestines in relieving hyperemia is sound, and by this means it probably prevents the formation of ulcers within the gut, places those which may have al-

<sup>1</sup>Zell. Path. Hyg. u. Bakt., 1890.

ready formed in a condition most favorable for their healing, preventing the acute inflammatory process and engorgement of the mucous membrane leading to the death of more tissue, and thus bringing about a cure.

### MEDICAL NOTES.

**Koch's FLUID IN BOSTON.**—The supply of Koch's fluid, received by Dr. H. H. A. Beach from Berlin, has been placed by him, in a true scientific spirit, at the disposal of the principal hospitals. In another part of this issue of the JOURNAL is an account of the preparation of the material for use, in an ingenious manner, by Mr. W. C. Durkee.

**MEDICAL EXAMINER.**—Governor Brackett has nominated William D. Swan, M.D., of Cambridge for the office of Medical Examiner for the first Middlesex District, vice Dr. Alfred F. Holt, deceased.

**THE NEW SURGEON-GENERAL.**—Dr. Charles Sutherland, who has recently been made Surgeon-General of the United States Army, entered the Medical Service of the Army in 1852, and was the ranking Colonel in that department. He served with distinction in the war, and was breveted Lieutenant-Colonel and Colonel for meritorious service. Since 1866 he has held the position of Assistant Medical Purveyor.

**PROFESSOR WEIGERT NOT DEAD.**—We are glad to learn that the report of the death of Professor Karl Weigert of Frankfurt, which has been published in several German and English papers, was incorrect. He has been suffering severely from septicaemia, but is now recovering.

**CHOLERA.**—With the official announcement to the effect that the cholera epidemic in Spain has come to an end, all information on the subject has ceased from that country. In Syria the disease is still seriously prevalent, Aleppo being the principal centre of mortality; but at Hamah, Antioch, and Homs, a large cholera mortality was also maintained up to the first of last month.

### NEW YORK.

**THE OFFICIAL BULLETIN OF THE NEW YORK STATE BOARD OF HEALTH,** just issued, shows that, as usual, November is the healthiest month of the year. The average daily mortality in the State for the past five years has been 260, while that of November has been 225. In 1889, there were forty-two deaths daily more than the daily rate for the year; in 1888, there were fifty-two less; in 1887, twenty-one less, and in 1886, nine less. The average number of deaths per day for 1890 has been 305, and during November, 257, a diminution of nearly fifty-six per diem. The mortality from zymotic diseases decreased proportionately from 155 deaths in each 1,000 from all causes in October to 146 per 1,000 in November. It was also lower than the average for November, which is 182 per 1,000. All zymotic diseases except diphtheria, scarlet fever and measles showed lower mortality.

Diphtheria always shows a marked rise in mortality in October, and the average of five years shows a continuance of this increase through the succeeding two months.

**OFFICIAL FEES.**—The Board of Supervisors of Dutchess County, which includes the city of Poughkeepsie, having for some time refused adequate pay for public services rendered by the medical profession, a large number of the physicians of the county recently sent to the Board a petition in which they stated their conviction that ten dollars was a just charge for an examination of a dead body before a coroner, and also for an ordinary examination in lunacy. They also announced that they would not perform the duties of coroner's physician or examiner in lunacy for a less sum than the above, and asked that these changes be fixed as legitimate rates. "We are forced to this action," the petition went on to say, "by the knowledge and belief that our services are misunderstood and our labors underrated; that our professional qualifications are gauged by the standard of the day-laborer, and that often in the past no account has been taken of our skill and ability nor of the dangers we have to encounter." On the 30th of December the Board of Supervisors, without debate, coolly laid this petition on the table; but if the great mass of the respectable practitioners of the County will only stand firm in the matter there can be little question that the supervisors will finally be obliged to come to their terms.

### Miscellany.

#### TOXALBUMIN AND IMMUNITY FROM DIPHTHERIA.

THE connection between toxalbumin<sup>1</sup> and the preventive inoculation against diphtheria by the injection of the products of bacterial growth, has recently been investigated by Fraenkel,<sup>2</sup> who finds that toxalbumin, when isolated, dried, and kept several months, possesses its poisonous qualities, and produces absolutely no immunity against the disease. But the culture fluid itself, sterilized by filtration or by heating for an hour at 55° C., although poisonous, will, if injected in non-fatal doses, so hinder the poisonous properties of virulent bacteria, subsequently injected, that an animal, instead of dying in one or two days, will live three to nine days. The next step was the discovery that more complete immunity could be obtained, not by small doses of the poisonous culture fluid, but by large doses of the same fluid made non-poisonous by heating for an hour to 100° C. By experimenting with fluids obtained from bouillon cultures of the bacillus of diphtheria raised to different degrees of temperature, he concluded that the best results could be obtained by heating for an hour at between 66 and 70° C. Ten to twenty cubic centimetres of culture fluid prepared in this way, at the end of three weeks protected guinea-pigs subsequently inoculated with virulent bacteria. The author concludes that the specific

<sup>1</sup> See page 430 of the Journal.

<sup>2</sup> Berliner Klin. Wochenschrift, No. 49, 1890.

poison generated by the diphtheria bacillus and the material which produces immunity, are two distinct substances. In the culture fluid they both exist. The former begins to lose its properties at from 55 to 60° C. The latter can endure a higher temperature, but above 70° C., it becomes weakened.

This preventive substance is therapeutically of no use. If animals are infected with virulent bacteria, and immediately afterward receive an injection of the substance, no immunity is obtained; on the contrary, they die rather faster than without the injection. The method is therefore not applicable as a cure for diphtheria, although the possibility is suggested that a similar process may be of use in infectious diseases which have a long period of incubation.

### PRESCRIPTIONS.

**PEDICULI PUBIS.** — Brocq<sup>1</sup> uses the following lotion:

R Corrosive sublimate . . . . . gr. v.  
Vinegar . . . . . 3 ℥. M.

This not only kills the pediculi, but also detaches the nits.

Hebra recommends this ointment:

R Calomel . . . . . 53 3 j.  
Bismuth, subnitrat. . . . . 3 j.  
Unguent. simp. . . . . 3 j. M.  
Ft. unguentum.  
Sig. Rub on thoroughly twice a day.

**CREOLIN IN ERYSIPELAS.** — Rothe<sup>2</sup> has used in the treatment of erysipelas the following ointment:

R Creolin . . . . . gr. xxiv.  
Cret. prap. . . . . 3 j.  
Adips . . . . . 3 j. iv.  
Oil, menth. pip. . . . . grs. v. M.

This is spread in the thickness of the blade of a knife over the diseased parts twice or three times a day, a thin layer of cotton wool being applied as a covering. The same ointment also did good service in a case of weeping eczema of the face, as also in several cases of eczema in children. A patient suffering from scabies was treated with a thorough washing with soft soap and innunction of this ointment, with such a decided effect, that Dr. Rothe considers creolin to be undoubtedly a specific for the disease.

The method of Koch<sup>3</sup> consists in applying, by means of a camel-hair pencil, the following ointment in a perfectly thin layer over the affected parts:

R Creolin . . . . . 1 part.  
Codonum . . . . . 4 parts.  
Lanolin . . . . . 10 parts. M.

After the ointment is applied, it is covered with a thin layer of gutta-percha. This method is said to be especially applicable to erysipelas of the face and of the hairy scalp.

### Correspondence.

#### THE FIRST ADMINISTRATION OF ETHER.

Boston, January 3, 1891.

MR. EDITOR: Dr. Jewett communicates in the last number of the JOURNAL an incident connected with the first public surgical operation under ether by Dr. Warren, on October 15, 1846, which he is quite right in thinking

<sup>1</sup> Gazette de l'Hopital, etc.  
<sup>2</sup> Reich's Archiv f. Klin. Chirurg., November, 1890.  
<sup>3</sup> The Lancet, Gazette, October 15th.  
<sup>4</sup> The Boston Medical and Surgical Journal.

has not been published. The reason is that it did not occur on that occasion.

It appears from Dr. Jewett's account (1) that the patient was a woman; (2) that the operation was for a malignant tumor of the upper jaw; (3) that through defect or mismanagement of the apparatus the patient was asphyxiated and suffered no pain. In confirmation of all which Dr. Jewett tells us that he sat where he could see the minutest details.

Nevertheless, the facts are, (1) that the only patient operated on under ether by Dr. Warren at the first public trial on October 16, 1846, was a man; (2) that the operation was for a vascular tumor of the neck; (3) that far from being in need of resuscitation, the patient was not profoundly unconscious during the operation, but spoke incoherently during the latter part of it, and experienced some pain.

The reason why it is worth while to correct Dr. Jewett's reminiscences is that a serious charge is implied; to wit, that the anesthesia obtained at the first surgical operation was due to asphyxia, but was represented as the effect of ether. This is very certainly untrue.

I do not doubt that Dr. Jewett's error arose from a lapse of memory, and that such an accident as he describes may have occurred on a subsequent occasion. This, however, entirely changes its significance.

Dr. Jewett must excuse me for saying that he was boned to be sure of his facts before making such a statement.

Very truly yours, THOMAS DWIGHT, M.D.

### THE STUDY OF MUSHROOMS.

#### A REPLY AND CORRECTION.

Boston, January 3, 1890.

MR. EDITOR:—The tone of the article in your issue of December 14th, signed Julius A. Palmer, Jr., would imply that the slight criticism of his book of plates had so obscured his vision that he did not, or would not, perceive that it was distinctly stated that the list was not a bibliography, but only a list of those considered by the writer to be of use to the casual student. He goes out of his way to say that the list is "strangely incomplete," because it did not include some articles from his particular pen.

He knows full well that ignorance of the authorship of the article in "Appleton's" was impossible, as it was seen in proof and several changes urged, some of which were accepted. Having been considered competent by the author to look it over before publication, the writer considered he was "competent to judge of its merits," and was convinced that instead of being "the most valuable ever published," it was "strangely" misleading in some of its statements, and for this reason it was not mentioned.

The article, erroneously credited by a printer's error to Julius A. Palmer, Jr., and which your correspondent considers the poorest he ever wrote, is really one of the best popular articles, and one most likely to stimulate research in this most fascinating subject.

Why your correspondent should say that "more recently" than "a year or two ago" he loaned two quarto volumes of correspondence to the writer, or what connection such a loan had to do with the article of October 2d, it is difficult to imagine. It was over four years since, with his permission and for the specific purpose of collecting the cases of poisoning he had noted, that the writer had the use of his volumes. His cases, thirty-three in number, were published in the writer's pamphlet on "Mushrooms and Mushroom Poisoning," and full credit given him therefor. Credit was also given him for the first set of plates issued in this country, and also for his zeal in essaying the edible qualities of many varieties, and again for having the courage of his conviction that those fatally poisonous were all to be found among the Amanitas.

Writing of his "Mushrooms of America," the writer stated "that while not in every instance correct as to the

botanical nomenclature has most excellent plates, which are invaluable to the beginner." To this he took exception in a personal letter, and asked wherein had been noticed any errors, and expressed surprise that the charts of Smith were so unhesitatingly recommended, apparently forgetting he has done the same in his "Appleton" article. Had he been satisfied to await an answer and not appeared in print, these criticisms would have been sent to him, and your indulgence not asked for this reply.

Writing from memory, only one or two errors were in mind, but since making a critical examination of his plates and text, the conclusion has been reached that, instead of words of commendation, it should have been written simply, "had some plates valuable to the beginner," meaning that they were valuable as being the only available set of plates easily procurable at a low price, and likely to stimulate the student to further research, that he might be able to separate the wheat from the chaff. Having written as he did, and having been told by a bookseller that his pamphlet had "caused a boom for Palmer's book," the writer feels that it is his duty to call attention to some of the many inaccuracies of the work, not only as to the nomenclature, but in general, as he fully believes that it is as important to note error as to elucidate truth.

To begin with, Plate I, Fig. 1, of *A. campestris*, lacks the distinctive delicate pink or flesh color, by which it is so easily recognized, and from which it derives its common name of Pink Gill. At the stage of growth, just bursting its veil, in which *A. arvensis* (Fig. 2) is depicted, the gills should be white, not dark as given. The spores of *A. cretaceus* (Plate IV) are "wholly, as is *A. campestris*" (*vide* Stevenson, vol. i, p. 304), that is, dark brown, not "pink or rosy" as stated. The long stems, which are so characteristic of *A. procerus* (Plate V), have been amputated at about their middle, that the figures might fit the page, thus sacrificing the truthfulness of the otherwise good pictures. To say that "equal gills are characteristic of the whole *Russula* family" is contrary to all good authorities, as Fries, Berkley, Cooke, Stevenson and others, for the tribe *Compactae* of this genus all have unequal gills. A strong imagination is needed to discern any warts on Fig. 3, Plate VI, as called for by the description of *R. virescens*. Fig. 2, *R. heterophylla*, has a pileus, very variable in color, but all authorities agree that it is "never reddish or purple," which latter is certainly the color as represented in this plate.

Plate VII, Fig. 3, lacks the blackish points or dots on the stem, so characteristic of *B. scaber*. Fig. 4 is probably *B. miniato-olivaceus*, certainly not *B. sub-tomentosus*. Fig. 5 omits the cracks on the cap, to make it a typical *B. chrysenteron* or red-cracked boletus. The coloring of Fig. 6 is very poor, but corrected by the text.

Plate VIII, Fig. 1, is a very good representation of, and should be named, *L. cyanthiforme*, it lacks the shape of *L. giganteum*, which is depressed, globose, the vertical diameter being less than the horizontal, the former occurs more frequently and in greater numbers. They are easily distinguished by the color of the spores, in the latter they are yellowish-green and dingy-olive, in the first they are purple-brown. Fig. 2 gives no idea of a long *stemon* or elongated puff-ball, the common name of *L. saccatum*.

Plate X, Fig. 2, will answer for a poor representation of *A. muscarius*, if it is intended that the coloring on the cap should indicate warts. Fig. 3 is not *A. phalloides*, but is *A. mappa*, as is Fig. 4, if we except the striations on the margin of the pileus. Warts are not found on the cap of *A. phalloides*, the volva in this variety bursting at the top, allowing the pileus to appear quite naked.

Plate XI, Fig. 1, does not show the reticulations on the stem, which are so characteristic of *B. felleus*. Figs. 3 and 4 are given as *B. luridus*, but as authorities say that the pileus should be *unber olivaceus* and the pores *vermillion then orange*, this is clearly a case of incorrect nomenclature. To say that "Fig. 3 is easily confounded with Figs. 4 and 5, Plate VII," would imply that the observer was or had been asleep, or possibly color-blind, for scarcely any three of the figures of boleti are more unlike, the species them-

selves are very distinct, and in no way likely to be confounded.

Enough has been given to justify the statement, "not in every instance correct as to botanical nomenclature," and also to show that the work has other inaccuracies.

The writer's acquaintance with "the various authorities" so "carefully studied and collated" years ago by your correspondent has not led him to agree "that a uniform system of nomenclature is a desideratum," but has convinced him that the one we have should be correctly employed.

Yours very truly,

EDWARD JACOB FORSTER, M.D.

## RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, DECEMBER 27, 1890.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 27, 1890, TO JANUARY 2, 1891.

By direction of the Secretary of War, Captain WILLIAM J. WAKEMAN, assistant surgeon, is relieved from the further operation of Paragraph 15, Special Orders 354, Adjutant General's Orders, October 20, 1890, and telegraphic instructions of the 10th instant, from this office, transferring him from Fort Bidwell, California, to Fort Huachuca, Arizona Territory, and he will return from Reno, Nevada, to Fort Bidwell, for further duty at the latter post. S. O. 500, Par. 3, A. G. O., December 24, 1890.

By direction of the Secretary of War, First Lieutenant OGDEN RAFFERTY, assistant surgeon, is relieved from duty at Fort Sam Houston, Texas, and will report in person to the commanding officer, Camp Eagle Pass, Texas, for duty at that station, reporting by letter to the commanding general, Department of Texas. S. O. 501, Par. 2, A. G. O., December 26, 1890.

By direction of the Secretary of War, the extension of leave of absence on account of sickness, granted Major STEVEN G. COMBERRY, surgeon, in Special Orders No. 255, December 16, 1890, from this office, is still further extended one month, on account of sickness. S. O. 502, Par. 8, A. G. O., Washington, D. C., December 27, 1890.

By direction of the Secretary of War, Major JOHN S. LAXDER, surgeon, now on duty at Fort Ontario, N. Y., will proceed, without delay, to Pine Ridge Agency, South Dakota, and report in person to Brigadier-General JOHN BROWN, for duty in the field, and by letter to the commanding general, Department of Dakota. S. O. 503, Par. 8, A. G. O., Washington, D. C., December 29, 1890.

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 3, 1891.

G. M. PICKRELL, assistant surgeon, detached from U. S. S. "Minnesota," and wait orders.

A. M. D. McCORMICK, assistant surgeon, ordered to the U. S. S. "Minnesota," as Dr. Pickrell's relief.

## SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT. The annual meeting of the Society will be held on Monday, January 13, 1891, at the Medical Library, 19 Boylston Place, at 8 o'clock P. M.

Dr. J. Bonney will read a paper on "The Treatment of Eczema by Electrolysis and Apocath." By the following officers: G. G. SEARS, M.D., Secretary.

MEDICAL SOCIETY OF THE STATE OF NEW YORK. The February 18th Annual Meeting will be held Tuesday, Wednesday and Thursday, February 18, 19th and 20th, in the City Hall, at Albany, commencing at 9 A. M. Tuesday, and ending at noon, Thursday.

Commenced on a relation to the presentation and reading of

papers or to any changes in the provisional programme, already issued, should be addressed to the business committee prior to the 25th of January.

HERMAN BENDELL, 178 State St., Albany.

SENeca D. POWELL, 12 West 40th St., New York.

JAMES D. SPENCER, Watervliet.

Albany, January 8, 1891.

DR. ORLANDO W. DOE.

## RESOLUTIONS OF THE VISITING STAFF OF THE BOSTON CITY HOSPITAL.

BOSTON, January 1, 1891.

At a meeting of the Visiting Staff held this day, it was voted that a copy of the following resolutions on the death of Dr. O. W. Doe be forwarded to the Boston Medical and Surgical Journal.

From the time of his appointment as house officer, Dr. Orlando W. Doe has rendered long and devoted service to our Hospital. The same fidelity, care and patience, which were conspicuous in his private practice, he has given to the inmates of this institution.

These characteristics marked him as a conscientious physician. Such a character and such services cause us to deplore our loss, as we admire them. Let our regrets be not unavailing, but stimulate us to a higher sense of our professional duty.

DAVID W. CHEEVER,  
JOHN G. BLAKE,  
A. M. SUMNER, } Committee.

A true copy from the records.

Attest:

EDWARD J. FORSTER, Secretary of the Visiting Staff.

## OBITUARY. THERON TEMPLE, M.D., M.M.S.S.

Dr. Theron Temple, of Waltham, died, December 28th, aged fifty-seven. He was born in Heath, Mass., and graduated from the Berkshire Medical School. He practiced medicine for about twenty years in Amherst, and eight years ago moved to Waltham, where he served for a year as city physician. At the time of the war he enlisted as surgeon in the Twenty-fifth Massachusetts Infantry.

## DEATHS.

Benjamin F. Richardson, M.D., formerly Professor of Diseases of Women and Children in the Miami and Ohio Medical College, died, December 24th, aged seventy-three.

John Davis, M.D., formerly Professor of Anatomy in the Miami Medical College, Physician to the Cincinnati Hospital, died, December 25th, aged sixty-nine.

Wilhelm von Edinger, Physician Accoucheur to the Empress of Russia, and a member of the Russian Medical Council, died, on November 8th, aged seventy-one.

## BOOKS AND PAMPHLETS RECEIVED.

Desk Pad. Maltine Manufacturing Company.

Annual Report of the Postmaster-General of the United States for the Fiscal Year ending June 30, 1890.

The Fifteenth Annual Report of the House of Mercy, Pittsburg, for the Year ending November 1, 1890.

Removal of Tonsillar Hypertrophy by Electro-Cautery Dissection. By Edwin Pynchon, M.D. Reprint. 1890.

On Aphasia or Loss of Speech, and the Localization of the Faculty of Articulate Language. By Frederic Bateman, M.D. Second edition. London: Jarrold and Sons.

Cases of Cutaneous Tuberculosis, with Histological Studies. By John T. Bowen, M.D., Assistant for Diseases of the Skin, Massachusetts General Hospital. Reprint. 1890.

Antisepsis and Asepsis Before and After Major Gynecological Operations. By Howard A. Kelly, M.D., Professor of Gynecology in the Johns Hopkins University. Reprint. 1891.

Œuvres Complètes de J. M. Charcot. Hémorragie et Ramollissement du Cerveau, Métallothérapie et Hypnotisme Electrothérapie. Tome IX. Paris: Aux Bureaux du Progrès Médical. 1890.

Abnormal Intra-Thoracic Air-Pressures and their Treatment, Addressed at the Seventh Annual Meeting of the American Climatological Association, September 2, 1890. By Charles Denison, A.M., M.D., of Denver, Col., President. Reprint. New York. 1890.

On Chimisme Stomacal (Digestion Normale, Dyspepsie). Par M. M. G. Hayen, Professeur à la Faculté de Médecine de Paris, et J. Winter, Préparateur du Laboratoire de Thérapeutique à la Faculté de Médecine de Paris. G. Masson, Editeur. Paris. 1890.

## Original Articles.

THE PARASITIC ORIGIN OF CANCER.<sup>1</sup>

BY J. COLLINS WARREN, M.D.

THE achievements of bacteriology have not only aroused the hope that diseases hitherto considered incurable may come within the grasp of modern therapeutics, but have also emphasized the fact of our complete powerlessness in the presence of cancer, except with the uncertain aid which the knife has given us.

The etiology of cancer still remains an unsolved riddle. Any work in this domain of pathology deserves, therefore, all the encouragement which a sympathetic professional public can give, as it is but the preliminary step in a direction towards which many eyes are straining, and which may point the way to that goal which the surgeon has hitherto sought for in vain.

The following notes, collected for the purpose of instruction to a medical class, are presented as some of the most recent contributions to this question, and are, perhaps, of sufficient novelty to interest the members of this Society. It would, of course, be futile to draw any well-defined conclusions as yet from the work that has been done.

## BACTERIA IN CANCER.

Scheuclen reported in 1887 a cancer bacillus, which he had obtained from cultures of ascites and hydrocele fluids, inoculated with material taken from cancer of the breast. On the third day a colorless film was seen on the surface of the serum, which changed to a yellowish brown color. Under the microscope the culture was found to be composed of short bacilli, two micromillimetres long and four-tenths of a micromillimetre wide, with spores, which could readily be stained with the ordinary reagents. They could not be found in colored section, but were obtained from the cancer juice. Inoculation of bitches by injecting material from the pure culture into the posterior breast gland, produced at the end of fourteen days, a circumscribed tumor the size of a walnut. In the animals, killed four weeks after the inoculation, the tumors were found to be composed of epithelial cells, in which the spores of the bacilli could be seen. Francke, at the same time (1887) made similar investigations with sarcomata, and obtained a bacillus of sarcoma. He also obtained the cancer bacillus from carcinomatous growths. The sarcoma bacillus measured three to four micromillimetres in length and four-tenths of a micromillimetre in width. He obtained cultures, but inoculations failed to produce malignant growths. These observations have not been confirmed by subsequent observers; and Senn, Baumgarten, and others, are not disposed to accept them as the micro-organisms of malignant disease.

## PROTOZOA IN CANCER.

The many striking little bodies which have so long been recognized as characteristic of epithelial cancer under the name of epithelial nests — *globes epidermiques* — have recently been studied with renewed interest. The glistening bodies which form the centres of these masses, around which the epithelial cells appear to be arranged concentrically, were supposed by some to be epithelial cells in a state of

colloid degeneration or cells having undergone the horny change. Virchow, however, as early as 1861 did not accept this view, but named them physalides, (*physalis*, a bladder), or broad cavities; and this idea of an endogenous cell formation was adopted also by Butlin in his description of Paget's disease of the nipple. Within the last few years the view has been gaining ground that, these cells existing within the epithelial cells did not belong to the human organism, but were animal parasites of a very simple organization, consisting only of a single cell, and properly classified as one of the very numerous forms of protozoa.

The sporozoa, to which grand division of the subkingdom of the protozoa, the organisms in question belong, are described by Balbiani,<sup>2</sup> as being composed of five different species of organisms, namely: The gregarineum, the coccidium, the sarcosporidium, the myxosporidium and the microsporidium.

The sporozoa are parasites that are widely distributed. We find them in all animals, from man down to the infusoria. Some of them give rise to epidemics of a grave character in animals, as the coccidium in the rabbit — quite a common disease in France but rarely seen in this country. The sarcosporidium gives rise to an epizootic in sheep and poultry. A number of fish die annually of disease produced by the presence of the myxosporidium. And the organism which has caused such ravages among the silk-worms of France, producing the *maladie de la pébrine*, is the microsporidium.

The gregarinidia are elongated cells, showing a tendency to sub-division by the presence of constrictions. They each have a single nucleus. When sporulation takes place two cells enter into conjugation and form a single cyst with a wall of double contour, in which are formed the spores which are each enclosed in a diatom-like capsule. They were for this reason called the pseudo-navicellæ. When the condition favorable for the segmentation of the spores occur, two or more sickle-shaped cells form in them. These cells have amoeboid movements, and entering a new cell remain there until they become a fully developed cell, at which period their life becomes an extra-cellular one.

The coccidia, which interest us especially, owing to their presence in epithelial cancers, are somewhat similar in their structure to the gregarinidia. They differ materially from the latter organisms by the prolonged intercellular life. The organism consists of finely granular masses of protoplasm, with a nucleus not easily seen, and without an enveloping membrane during its period of growth. During this period it lives in an epithelial cell, where it finally becomes encysted. Before the protoplasm of the organism becomes segmented and sporulation takes place, it breaks away from the epithelial cell, and may be voided from the intestine of the infected animal. After sporulation occurs, it may again be taken into the digestive tract of another animal, somewhat after the manner of more complex animal parasites.

The coccidia are divided into several sub-varieties, according to the method of spore formation.

Steinhau describes the changes of the coccidium in the intestinal tract of the salamander, which, however, differs in certain important particulars from that of Balbiani. The different stages of the peculiar sickle-shaped cell-formation are very beautifully illustrated.<sup>3</sup>

<sup>2</sup> *Lçons sur les Sporozoaires*, Paris, 1884. *Médecine Chirurgicale Transactions*, 1887.

<sup>3</sup> Virchow's Archiv., Band 115, H. II, p. 176.

<sup>1</sup> Read before the Boston Society for Medical Improvement, November 21, 1890.

The cells he describes have nuclei and nucleoli; they entered the nucleus of an intestinal epithelial cell; sometimes there are one or more such cells in the nucleus. The nuclei of the parasites presently begin to divide and sub-divide until a necklace of nuclei may be seen in the interior of the organism now grown so large as to have distended and ruptured the epithelial nucleus which contained it. The next change is the formation around these nuclei of the sickle-shaped cells which are disposed around the surface of the organism like the meridians of a globe. Later, these cells become detached from one another, change their shape, and when ready for release appear as amoeboid corpuscles ready to invade a new cell. Steindlaus saw no enveloping membrane, and the changes above described all occurred inside the epithelial tract. One of the best known forms is the coccidium oxiforme, which is found in the intestine and liver of the rabbit, where it forms caseous nodules. Here the cyst formation is well-marked, and occurs within the epithelial cells, whose nucleus is pushed to one side. The further development of the cyst contents is extra-cellular in this case. Balbiani has been able to cultivate them in water and wet sand and thus observe the changes which take place during sporulation.

Cases of caseous tumors in man have been described by Güdler, in which these organisms have been found; and Podwysoski has described, as karyoplagus hominis, organisms which attack the nuclei of the liver cells and after ovulation and sporulation destroy the liver cells, and lead to irritation of the connective tissue struma, giving rise to icterus and cirrhosis.<sup>4</sup>

The sarcosporidia are generally found in the muscular tissue of vertebrates. They are also called by Balbiani, *Les Psorospermies utriculiformes*. These long tubes form at the expense of the muscular fibre. They are seen in pork easily, with a power of forty diameters. Finally, spores form partly in globular masses and partly singly. The cells which form vary in shape.

The myxosporidia are found in the skin and mucous membrane of fishes. The spores present a much greater variety of forms and more complex structure. They are provided with projectile threads.

The microsporidia are so called by Balbiani on account of the extremely small size of their spores, which are not more than four micromillimetres by two micromillimetres. They have been occasionally mistaken for bacteria. They possess a sac with a double contour, which can readily be distinguished when it ruptures at one end, and allows its contents to escape. These appear as amoeboid bodies which penetrate the epithelial cells, muscular tissue and other structures of the silk-worm and develop into sarcoid masses, in which sporulation takes place. The parasite penetrates into the reproductive, and other organs, and does not confine itself to the epithelial cells.

That the pathogenic qualities of the sporozoa, or the *psorosperms*, as the French authors call them, were in fact confined to animals, has been recognized in many years. One of the earliest communications is Guber, in 1766, upon the growth of these organisms in man, he already been referred to. It has been thought possible that the growth described by another was a glandular cell cancer of the liver in a case of reticulosarcoma metamorphosis. Coccidia have been found in the intestinal canal of man, in

pleuritic effusion, and in the interstitial tissue of the kidney in a case of Bright's disease.

The contagious nature of molluscum contagiosum was proved by Retzius in 1870, by inoculation experiments; but Neisser, in 1888, first showed that the "molluscum corpuscles" supposed to be the result of a degenerative process, were really parasitic. He succeeded in tracing them through their different stages of development and in identifying them with the coccidia. According to him, these corpuscles consist of epidermic cells containing the remains of nuclei and filled with spores, and that the disease itself is due to the invasion of the cells of the rete mucosum by these parasites. The glandular appearance which has always hitherto suggested the sebaceous origin of these tumors, is now recognized as due to a papillary growth of the malpighian layer of the skin. The name epithelioma contagiosum has been suggested as a more appropriate name for the affection. A contagious skin disease in poultry originally described by Bollinger in 1873, as seated in the epidermic layer of the skin, is shown by Pfeiffer to be due to the invasion of the coccidium. The disease may be artificially produced by inoculating the spores; but if planted in the mucous membrane of the throat instead, it will produce a diphtheritic inflammation which is very contagious. In this case the spores assume a flagellate instead of amoeboid form. As Wright intimates this polymorphism is of great interest, in view of the remarkable, and as yet only partly understood polymorphism of the malarial parasite.

A rare form of disease of the epithelial layers of the skin in man was described simultaneously by Darier<sup>5</sup> as *psorospermose folliculaire végétante* and by J. C. White<sup>6</sup> as keratosis follicularis. Darier attributes the disease to the presence of organisms resembling the coccidia. According to his description, we find a papillary-like growth of the cells of the rete near the neck of the hair follicle, the sebaceous gland not being affected. Near the neck of the follicle the anatomical arrangement is more like that of the skin. In the malpighian layer at this point he found a number of round bodies with a glistening membrane of double contour which looked not unlike cartilage cells in their capsule. The enclosing membrane contains a granular protoplasm which nearly fills it, and has a nucleus with nucleoli. On treating a mass of epithelial cells in potash, he found these bodies could be isolated, or they could be well demonstrated by softening the cells in ammonia and coloring them with hematoxylin. In the deeper portion of this epidermal mass these organisms can be seen situated in the interior of epithelial cells. The epithelial cells elsewhere do not appear to have undergone any degeneration to account for the presence of such a body. He concludes that they are probably of parasitic origin. Both Malassez and Balbiani, by whom the specimens prepared by Darier were examined, agreed that these bodies were well marked examples of the coccidium. Malassez claims to have recognized since 1876 that the granular and highly refractive cells seen in epithelial growths and which are sometimes enclosed in a membrane, presented certain analogies to the *psorosperms* of the rabbit. In two cases observed with Allbarrau, he was able to demonstrate that the organisms were really coccidia, but he did not feel able to state definitely

<sup>5</sup> La Semaine Médicale, 1889, 101.

<sup>6</sup> Journal of Cutaneous and Genito-Urinary Disease, June, 1889.

that the tumors were the cause of the new formation. These were demonstrated to the Société de Biologie, in 1889.

But these organisms are not found in the so-called epithelial cancers alone, that is in cancers of the skin. Thoma<sup>7</sup> found the coccidia in cancerous growths of various organs, usually in the nucleus but also in the protoplasm of the cells. They were readily shown by eosine and hæmatoxylin staining, but his descriptions are incomplete. Paget's disease of the nipple, or as the distinguished author himself called it<sup>8</sup> "Disease of the mammary areola preceding cancer of the mammary gland" has been restudied recently by Wickham<sup>9</sup> who, together with Darier, had found the coccidium not only in the preliminary eczema of the nipple, but in the subsequent disease of the gland.

In the earlier stages of the affection the only change to be noted is the presence of certain cellular bodies in the malpighian layer which are clearly not epithelial in nature. They are generally considerably larger than the cells of that layer: They take the staining differently, and have a decidedly different grain to their protoplasm, but one of their most striking peculiarities is that they are usually retracted into angular masses, and thus leave irregular clear spaces between themselves and the surrounding epidermic cells, a contraction probably due to alcohol. A certain number of them are enclosed in a hyaline membrane of double contour, and when the alcoholic shrinkage occurs, the protoplasm of the cells separates from the membranes which remain in contact with the other cells. Some of these bodies are round or oval, and present, with their thick and glistening capsules, a striking appearance. We often see several nuclei, some of which are quite large and irregular in shape.

One of the most characteristic features of these organisms is their seat within the epithelial cells; the nucleus of the containing cell being pressed aside by the parasite. The nuclei of the coccidia are situated sometimes in the centre and sometimes at the edge of the protoplasmic mass. The retraction of the latter gives the organism the appearance of a cell in a stage of degeneration, as has so often been attributed to it hitherto. This retraction gives the affected epidermis its cribriform appearance. When the number of these organisms is small they may not be seen at all in many sections. They are, however, easy to find in the scrapings from the cut surface of the diseased epithelium. Their size is about double or treble that of the adjacent cells, but occasionally they may be enormous, their diameters being nearly equal to one-third of the thickness of the rete malpighii. They are to be found in all the layers of the epidermic portion of the skin. They are more numerous near the first row of the cells of the rete; at this point they are rarely encysted but appear usually as a mass of nucleated protoplasm more or less retracted, in the centre of a clear space. Higher, the corpuscles are more frequently encysted and usually larger. In the horny layer they are usually flattened out, and hence are less apparent.

The parasites become more numerous as the disease progresses, and the intervening epithelial cells are much compressed and distorted in consequence. The structure is now filled with holes, the result of the retraction of the protoplasm of the coccidia. The

large cells above mentioned are veritable cysts containing a granular material in which are a number of oval corpuscles. The appearance is not unlike that of a miliary abscess except for the enveloping membranes. It appeared to Darier that these cysts rising near the surface of the horny layer in consequence of the epidermic proliferation allowed their contents to escape and to become mingled with the *débris* which goes to form the scab. Around the cysts we see the cells of the rete very much compressed and arranged concentrically and we generally see at the border of the cyst wall the flattened-out nucleus of the cell which contains it, the remainder of the cell being recognized by a line which more or less completely encloses the cyst wall. It is in this way that the well-known epidermic bulbs are formed. As to the future life of these organisms; some of the cysts appear to be thrown off from the surface in the desquamation and scabbing which occurs; others after rupturing, spread their contents in the surrounding tissues. Some of the larger cysts show a dilatation at one of its peripheral portions which is probably a change preparatory to rupture of the cysts after which the amoeboid bodies escape between the cells of the rete and eventually forcing their way into new cells, continue the process of development at the expense of their protoplasm. These corpuscles may also come in contact with an excoriation of the surface and penetrating the epidermis, start a new centre of growth. It is possible that the original infection may take place in this way. One of these corpuscles may become implanted between the papillæ of the nipple during washing, as we know that the coccidia live in water. Or they may become attached to the orifices of the large sebaceous glands of the scrotum and penetrate the epidermis at some excoriated point.

Wickham tried inoculation in a number of rodents without obtaining any result. He also inoculated himself by scarifying the epidermis of his right forearm and planting upon the raw surface a pulpy mass of scales suspended in distilled water. A glass crystal was placed over the wound and kept there eight days with a negative result. Cultures of similar masses upon moist sand which had been previously sterilized gave the following results: At the end of sixteen days while the other cells had lost their distinctive characteristics the cysts were perfectly well preserved. Wickham thinks there is no reason to doubt the true nature of these organisms. It might be supposed that these cells were in the process of vacuolation, but the contraction of the protoplasm takes place around the nucleus and does not push it to one side. The readiness with which the protoplasm and nuclei are colored are also arguments against a degenerated structure.

According to Wickham these organisms exert a direct pathogenic action upon the epithelial cells and as the result of the irritation thus produced the cells return sooner or later to an embryonic state and their future proliferation and active growth appear to be caused exclusively by these organisms, which find in these new epithelial growths an excellent culture soil.

Cornil has seen similar organisms in certain cancers of the uterus and the coccidia have also been observed in cases of rodent ulcer.

In all these forms of epithelial disease the epithelial nests are, as you know, a familiar sight. It becomes a matter of much interest to determine therefore

<sup>7</sup> Über eigenartige parasitäre organismen in den epithelzellen der cutaneum. Forstsch. d. Med., 1889, No. 11.

<sup>8</sup> St. Bartholomew's Hospital Reports, 1871.

<sup>9</sup> Maladie de Paget, Paris, 1890.

whether similar organisms are to be found in other forms of cancer in which the epidermic structures are not found.

Nils Sjöbring's communication upon the presence of a protozoa-like organism in several cases of cancer of the breast examined by him are therefore of special interest at this time. The tumor from which most of his preparations were obtained was a typical cancer of the breast, of the medullary type. It was hardened in alcohol, imbedded in paraffine, and cut with the microtome. Staining was produced by Ehrlich's hæmatoxyline and eosine method, and cleared up in xylolalium.

What first called his attention to these organisms was their deep-red staining in contrast to the pink color of the surrounding elements.

In the earliest stages of its growth the organism in question appears as a small, round, protoplasmic body, about two micromillimetres in diameter. Several of them are found in each alveolus. One of the peculiarities of this little structure appears to be that, having entered an epithelial cell, it proceeds to penetrate the nucleus, where it remains during the early stages of its development. Such a habitation of the nucleus is mentioned by Steinhaus in his description of the coccidia of the salamander; but none of the French authors mention such action of the organism in the epithelial growths.

These corpuscles are usually first seen near a nucleus, but they may be some little distance off. They are not found in direct contact with the contents of the cell, but are surrounded by a clear zone, as if they were in the middle of a space hollowed out of the interior of the cell. There is no lining membrane to this cavity, the walls of the cyst-like space consisting merely of a somewhat thickened layer of the adjacent protoplasm. This bright border, perhaps due to shrinkage of the protoplasm, serves to distinguish them readily from the nuclei of the cell. Having emigrated from the nucleus they appear now as irregular or flask-shaped masses of protoplasm still without a nucleus attaining the size of a diameter of fifteen or more micromillimetres. They do not have any well-defined cell wall. The organism enters now into the free stages of its existence, and may be found between the cells of the cancer or in the ducts of the mammary gland. It soon enters the cancer cells however, apparently to obtain sustenance from their nuclei. We see now large irregular protoplasmic-like organism in the protoplasm of the epithelial cell and separated from it by the bright zone. It may have already attached itself to a nucleus which it soon surrounds and encloses into its own substance so that the nucleus of the cancer cell is now embedded in the protoplasm of the parasite. Changes soon begin now to appear in the protoplasm of the cancer cell; its peripheral portion becomes pointed and takes staining feebly and finally it disappears altogether, or is pushed aside leaving the parasite in undisturbed possession of its nucleus. The next change is seen in the nucleus itself; it seems to be undergoing a breaking-down and assimilation into the substance of the parasite. The hyaline portion separate and collect in the shape of drops here and there in the neighborhood of a clump of chromatin granules. These drops soon become absorbed and give the protoplasm of the parasite a somewhat lighter color; the chromatin granules are either seen protruding from the edges of the cell or entirely

free in the neighborhood; they are apparently discarded; at all events, they disappear entirely. At this time the organism is found to be surrounded by a distinct membrane.

We now enter upon the next period in the development of the parasite, that of sporulation. The first indication of this process is the appearance of a number of dark-red points, which as they enlarge develop into bent rods with club-shaped ends. They are about three micromillimetres in length. As they develop it is seen that they are each enclosed in separate capsules. The organism finally becomes transformed into a cyst-like sack with a membrane which encloses a number of bright egg-shaped bodies, each of which encloses a spore. Eventually the membrane of the cyst is ruptured, and the spores are set free; and finally the small mass of protoplasm contained within the capsule is allowed to escape through a longitudinal rent on one side of its capsule. The amoeboid masses of protoplasm thus set free enter the nuclei of new cancer cells and begin again the cycle of development.

Quite a number of the organism in the first and second stages of its development are found in every alveolus. The fully developed spore cysts are, however, rarely seen.

The organism, it will be seen, has a very destructive influence upon the epithelial cells, and we see in the masses of detritus, when the cancer cells have broken down, a number of organisms which are evidently, from their shape and their coloring power, and other peculiarities, of a parasitic nature.

Sjöbring regards them as similar to that group of the sporozoa known as the microsporidium, or the organism which is the cause of the silk-worm disease.

The organisms were found by him in six out of the seven cases of cancer examined. In the seventh the inability to stain the nuclei of the cells showed that the specimen had not been properly preserved. The author has also found the microsporidia in a case of primary cancer of the liver, and in a primary cancer of the prostate gland. No culture experiments were made. Attempts have been made for a long time to inoculate cancer into animals or from one animal to another. Hanau succeeded in transmitting typical epithelioma from a rat to two other rats. He also succeeded in transplanting an epithelioma from one part of a man to another portion of his body, and in obtaining metastatic deposits around the implanted growth. At a recent meeting of the German Surgical Association Wehr showed three dogs, in whose peritoneal cavities cancer had been transplanted from a man; one of the animals died of cancer; the others were still alive, but had a number of nodular masses in the peritoneal cavity.

A recent monograph by Pfeiffer<sup>10</sup> describes the relation of the protozoa to certain pathological conditions, more particularly in animals.

---

— "Is the doctor in?" asked a tramp at the door of an Arch Street physician yesterday. A few minutes later an oldish female came to the door. "I just wanted to see if the doctor wouldn't give me a pair of his old pants," said the tramp. "I'm the doctor," replied the lady. The tramp had several attacks of vertigo as he dropped down the steps.—*Philadelphia Record.*

# A CASE OF RELAPSING APPENDICITIS IN WHICH THE APPENDIX WAS REMOVED IN AN INTERVAL BETWEEN THE ATTACKS; WITH RECOVERY.<sup>1</sup>

BY A. T. CADOT, A.M., M.D.

THE patient was a young and vigorous man of twenty-five. He was first seen by the writer on October 29, 1890. He had had a slight attack of pain in the right iliac region about a year before, which had lasted but a few hours, and the nature of which was not made out at the time. In the nine months that immediately preceded his visit to me, he had had three attacks of pain in the same region, severe in character, and lasting, in each instance, several days.

As the early history of these cases is of great importance I will quote at length the notes of the first two of these attacks, as taken at the time by Dr. C. V. Bemis, who took care of him during them, and to whom I am indebted for the very accurate account of the condition of things observed by him.

January 19, 1890, Dr. Bemis was called, and found the patient suffering great pain in the abdomen, localized mainly in the right iliac region. A tumor about half the size of the fist was readily detected in this region, and it was very sensitive to pressure. He had nausea and vomiting, and the pulse and temperature were moderately elevated. Rectal enemata were followed by large and repeated fecal discharges, and the pain lessened after several moderate doses of morphine had been given. From the first he made steady improvement, and on the sixth day he was so well that the doctor's visits were discontinued.

May 9, 1890, Dr. Bemis was again summoned to him in another attack of pain in the same region. Again there was vomiting and a good deal of tenderness in the cœcal region. This sensitiveness was not so localized as before, and there was no swelling to be detected. Enemata were again given, with but small result. Small doses of morphine controlled the pain, and on the following day he was quite comfortable. During this attack the urine was found to contain a considerable amount of uric acid, giving rise to the suspicion that the pain might be of a rheumatic character.

On October 20th, he had the third attack of excruciating pain, again in the right iliac region. He was at the time travelling in the West, and had to take a hundred mile ride in the cars, to reach Detroit where he could get accommodations in a hospital. During this trip his sufferings were almost intolerable; but after he reached the hospital and had proper treatment, he again rapidly recovered, and was well enough in eight days to stand the journey East. The doctors in Detroit made a diagnosis of appendicitis, and advised the removal of the appendix in an interval between the attacks.

Immediately upon his arrival in Boston he consulted me at the Massachusetts General Hospital in regard to the advisability of an operation for the removal of the appendix during the intermission. He was entirely free from any pain whatsoever, his bowels were regular, and, in short, he was entirely over his last attack.

Examination of the abdomen showed that it was soft, and easily examined. There was no tenderness in the right iliac region, and by deep palpation there I could

feel a little elongated mass which rolled under the finger. As it slipped to-and-fro under pressure the patient said, "there, if there is any tender place, it is where you are pressing now."

The recurrence of the attacks and their character made it seem probable that we had here a case of catarrhal appendicitis, and it seemed highly probable that the disease would continue to appear at intervals, with the possibility that an ulceration might at any time lead to perforation of the appendix with consequent peritonitis.

The patient's occupation, which was that of a wool buyer, obliged him to spend much of his time travelling about in wild parts of the country, often far from the beaten track, in regions where a skilful surgeon could not be had.

The risk of the operation had, therefore, to be balanced against the possibility of serious results if he had an attack, with perforation, when in some inaccessible region away from surgical help. The nature of these risks was thoroughly explained to him and his friends, and after considering the question carefully, they decided in favor of an operation.

This was accordingly undertaken on November 3, 1890. After the ordinary preparation for an abdominal operation, he was etherized, and an incision about three inches long was made in the linea semilunaris on the right side, the centre of the incision being over the point where the appendix had been felt. The cœcum was readily found, drawn out, and below its lower end the appendix was found strongly bent backward, and curved below the caput cœci, to which it was attached by a short meso-appendix. This was tied in sections and cut off, until the appendix had been freed down to its junction with the cœcum. It was then tied with fine but strong silk. The serous coat was cleared by a circular incision some little distance in front of the ligature. It was then peeled back like a cuff for some distance, and the appendix, that is, the muscular and mucous coats, were divided at a point much nearer the ligature. The serous coat was then brought over the end by sutures applied in the Lembert fashion, drawing the serous surfaces together in the manner employed to close the end of the intestine where it is cut squarely across.

Recovery after the operation was without incident. The patient sat up on the eleventh day, and went home on the sixteenth day perfectly well. At that time the examination of the right iliac region showed no tenderness nor fullness.

The examination of the appendix after removal showed it to be somewhat enlarged with thickened walls. A careful microscopic examination of it was made by Dr. William F. Whitney who reported that the thickening and stiffness of the walls was due largely to an infiltration or the several coats of the appendix with small round cells. Cross-sections showed the mucous membrane over a large part of the appendix to have been removed by ulceration, so that the epithelial surface was only retained in islands here and there.

The most important question in regard to these cases is when to operate. The decision of this question must be made in each case for itself. The case reported above is an example of a condition of things which must sometimes occur; where the reasons for the operation depend largely upon the occupation of the patient. One would not think of operating on a

<sup>1</sup> Read before the Boston Society for Medical Improvement, November 24, 1890.

patient who had had but three attacks of moderate severity and not accompanied by peritonitis, if the patient were living in or near a large city where he could be constantly under the eye of his surgeon, but if, as in the above case, the patient is for a large part of his time to situated that he cannot get skilled medical attendance, it may often happen that the risks of the disease are greater than the risks of the operation.

## RECENT PROGRESS IN THORACIC DISEASES.

BY GEORGE G. STARRS, M.D.

### A CASE OF PHTHISIS CURED BY FACIAL ERYSIPELAS.<sup>1</sup>

SCHAEFER reports an interesting case occurring in an inmate of one of the largest Bavarian prisons, in which phthisis was extremely prevalent, and under ordinary circumstances ran a rapid and fatal course. Soon after the patient's reception, he was attacked by pleurisy with effusion, after which he never fully regained his strength. The following year bacilli were found in his sputum, and well marked signs developed in the left apex, extending later to the right, with night-sweats, hectic, loss of weight, etc. A fatal termination was expected within a short time. After a sharp attack of erysipelas, however, which extended over the face and neck, the afternoon rise of temperature and the night-sweats disappeared, the bacilli diminished rapidly in numbers, and the physical signs gradually improved, while there was a corresponding gain in appetite and strength. At last accounts the patient was well and capable of doing light work.

Schaefer refers to a similar case reported by Waibel in the same journal two years ago.

### THE CURABILITY OF PHTHISIS.<sup>2</sup>

In the "Mittheilungen aus Dr. Brehmer's Heilanstalt für Lungenkranke in Görbersdorf" some interesting statistics are given as to the results of treatment of the 551 phthisical patients in that institution during the year 1888. Of these 8.8 per cent. were cured, that is, the local and general conditions were greatly improved, while the bacilli and elastic fibres had disappeared from the sputum and had remained absent for weeks or months; 13 per cent. were almost cured, the local and general conditions having considerably improved, but bacilli were still present in the sputum, though in reduced numbers. In the latter class of cases the results were proportionately good, according as the stage of the disease was early, and the figures are of peculiar interest from this point of view, for they show that of the 551 cases sent for treatment only 19 were in the first stage, that of consolidation, in all the others the process of breaking down having begun. They may also throw some light on the want of success in many cases in ordinary practice, where the disease may not be detected early enough, or else may not be treated with sufficient urgency. The record further shows by statistics the improvement which is possible in the great majority of cases apart from complete or proximal cure.

### TUBERCULOSIS IN THE LAIBACH PRISON.<sup>3</sup>

The value of cleanliness and antiseptic precautions in preventing the spread of phthisis is well illustrated

by the history of the prison at Laibach during the past few years. Previous to 1884 the most unsanitary conditions prevailed. The rooms were overcrowded and ill supplied with light and air, the prisoners were furnished with insufficient food, were put to severe work under the most unfavorable circumstances, and allowed far too infrequently access to the open air, while the isolation of the sick was impossible. Under such circumstances it is hardly surprising that many cases of tuberculosis occurred among the inmates. In 1884, under the direction of Dr. Keesbacher, an attempt was made to remedy the most glaring defects, a slight improvement in the food was made, a slight lessening of the work required, etc., but the changes were too small to produce any marked effect. What was possible, however, was a thorough cleaning and disinfection of the whole house, walls, floors and furniture. The patients were required to expectorate into sawdust wet with carbolic acid, and the evacuations were disinfected. The result was most gratifying. In the last half of that year, although isolation of the sick was still impossible, the amount of tuberculosis had sunk greatly and has since remained comparatively very low; thus in 1884 8.12 per cent. of all the convicts died of tuberculosis; in 1885, 5.12 per cent.; in 1886, 2.98 per cent.; in 1887, 3.58 per cent.; in 1889, 2.18 per cent.

### CREASOTE IN PHTHISIS.<sup>4</sup>

W. H. Flint gives a brief *résumé* of the literature of the subject, and refers to his own experience with the drug in seventy-three cases. It was administered by inhalation, by the mouth or by the rectum, either separately or combined. For inhalation, a solution containing equal parts of alcohol, chloroform and creasote was invariably ordered. For administration by the mouth, an emulsion composed of cod-liver oil 40 parts, and mucilage of acacia 60 parts, each drachm containing two minims of creasote, was found to be better borne than other combinations. In case the patient could be induced to temporarily adopt an exclusive milk diet, a larger amount of the drug could be given by thoroughly mixing the emulsion with the milk than in any other way, in a few cases 24 minims being given daily for several consecutive days before the stomach rebelled.

Rectal injections of milk containing the emulsion also proved very valuable, two to four minims being thus given every five or six hours.

The conclusions reached are as follows:

(1) That intrapulmonary and intratracheal injections of creasote are of doubtful utility and may be positively injurious.

(2) That for administration by mouth or rectum solutions and emulsions of creasote are preferable in most cases to capsules, pills or wafers.

(3) That milk is an excellent vehicle for the administration of creasote in solution or in emulsion.

(4) That each method of administering creasote used by the writer, namely, by inhalation, by mouth, or rectum alone, or by both these channels simultaneously, is useful, and may each be particularly adapted to individual cases. In suitable cases the most rapid progress seems to be made when all these ports of entry are utilized.

(5) That the best results for each individual attend the administration of the maximum quantity which this patient will bear. This quantity will rarely ex-

ceed 10 or 15 minims daily for any great length of time, while in many cases only two or three can be continuously administered.

(6) It is very important that the treatment should be uniform and uninterrupted, so that an effort should always be made, if intolerance of creasote be shown by any one mucous surface, to employ some other channel.

#### BACTERIOLOGY IN THE PROGNOSIS AND TREATMENT OF PURULENT PLEURISY.

Netter<sup>6</sup> has examined the effusion in 109 cases of purulent pleurisy, and has found a large variety of bacteria. Thus he has observed 51 cases in which the streptococcus was present; 32 with pneumococci; 14 characterized by the association of different species of microbes, and 12 instances of tubercular pleurisy. In the first three forms the histological examination and the cultures have shown what organism was concerned, while in the fourth the tubercle bacilli were not always found by microscopical examination. The failure to find tubercle bacilli does not justify the conclusion that the pleurisy is not tubercular, since inoculation of the peritoneum of rabbits with the pus sometimes gave positive results.

Clinical experience has shown that the pleurisy occasioned by pneumococci is much the most benign. It is most frequent in children, it often terminates by vomica. The pus should be removed by repeated aspirations before practising incision as a last resort.

Pleurisy from streptococci is more serious and more frequent in the adult. It is the type of classic pleurisy and in cases in which it is the cause, there is the greatest need for surgical interference. The pleural cavity ought to be emptied very early by thoracotomy and the organisms which have developed in its walls should be destroyed by the employment of a powerful antiseptic, such as sublimate; for without this treatment the germs are reproduced with great ease in the places where they have not been disturbed, and thence infect anew the pleural surface. There are, however, cases of pleural effusion due to streptococci which have recovered spontaneously after one aspiration. But as bacteriological methods do not determine the virulence of the streptococci in a given case it is better to employ early interference by thoracotomy. Putrid pleurisy demand the same early interference. They may heal without fistula. Tubercular purulent pleurisy do not heal by incision, but are improved by aspirations performed at long intervals.

#### ACUTE OBSTRUCTIVE DISEASES OF THE LUNGS.

A. H. Smith<sup>6</sup> says that in acute pulmonary obstruction, the danger being from exhaustion of the right heart, the pulse at the wrist does not give reliable indications as to the gravity of the condition. This can be more correctly appreciated by studying the pulmonary circulation by the aid of the pulmonary valve-sound, a marked accentuation of which indicates a fairly vigorous right heart laboring to overcome resistance in the pulmonary circulation. Decrease of such accentuation with only moderate dyspnoea, indicates diminishing pulmonary obstruction, while a decrease accompanied by increasing respiratory distress, shows that the right heart is becoming exhausted. Treatment is manifestly indicated which shall diminish

in every safe way the disparity between the venous and arterial supply, and thus relieve the right ventricle. Venesection in a certain proportion of cases is unquestionably of value, but in a majority its beneficial effects can be obtained by other and less objectionable means. In view of the changed conditions of congestion and hæmatisis the diet should be carefully regulated, as an excess of food may lead to flatulent distension of the stomach, and thus render the breathing more difficult, while at the same time there is risk of loading the blood with more nutritive material than the imperfect respiration can act upon in the process of sanguification. Such objection cannot be made to alcohol, which, apart from its value as a food, is also indicated for its stimulating action, as well as for its power to relax the arterial system.

Among drugs, nitro-glycerine and the nitrites are of the greatest value from the ability they give us of "bleeding a patient into his own veins." Again and again Smith has seen an apparently hopeless case of pneumonia relieved by drop doses of nitro-glycerine administered every fifteen or thirty minutes. Here the theory of spasm could scarcely be entertained, the relief coming from a transference of a mass of blood from the arteries into the veins. Digitalis, from its tendency to diminish the vascular area, is clearly contraindicated except in the exceptional cases of pneumonia marked by high temperature and great nervous exhaustion, in which the condition is due to the intensity of the affection and not to pulmonary obstruction. Much benefit may at times be derived from the inhalation of oxygen gas, and for temporary expedients artificial respiration or placing ligatures about the limbs may prove of great service.

#### ULCERATIVE ENDOCARDITIS.<sup>7</sup>

Truax reports six cases of ulcerative endocarditis with autopsy, in only two of which was the diagnosis made during life. Two of the cases presented such marked mental symptoms as to lead to serious error in diagnosis, and are worthy of special mention. The first case occurred in a domestic aged twenty-one. On admission to the Harlem Hospital, every muscle in her body seemed to take on choreic contractures, and she was unable to remain quiet a moment; her mind was confused, and she was at times delirious. She was supposed to be suffering from meningitis by the house physician, who had her head shaved and an ice-cap applied. At the autopsy a slight meningitis was found, but the chief interest centred in the heart, numerous vegetations being found on the mitral valve, some of which had ulcerated. The other case, which was correctly diagnosed by Truax, occurred in a gentleman forty-five years of age. He had complained of feeling badly for two weeks, but was not ill enough to call a physician. While waiting to be served in a restaurant he "suddenly jumped to his feet and taking hold of a chair commenced smashing everything within his reach." The following day he was very delirious, and required two attendants to keep him in bed. Another physician, a specialist in nervous diseases, was called in, who pronounced it an attack of acute mania, and advised his removal to an insane asylum, which was done. Death occurred three days later. At the autopsy the heart alone was examined, and the mitral and aortic valves were found to have vegetative growths upon them, one of which, of considerable size,

<sup>6</sup> American Journal of Medical Sciences, November, 1890.  
<sup>7</sup> American Journal of Medical Sciences, October, 1890.

<sup>7</sup> Journal of the American Medical Association, March 29, 1900.

had ulcerated. In three of the most malignant cases the heart was examined and cultures made for micro-organisms, but with negative results.

#### THE SIGNIFICANCE OF THE PULSUS DIFFERENS.<sup>8</sup>

Von Ziemssen compares the sphygmographic tracings of the right and left radial artery in four cases of aneurism of the arch of the aorta, with similar tracings from four cases in which atheromatous changes alone were present, and says that a study of these observations shows conclusively that the pulsus differens is not due to aneurism, *per se*, of the ascending or transverse portion of the aorta. When found it is most frequently produced by a narrowing of the orifice of the affected vessel from endarteritis, but it may, of course, result from a slit-shaped deformity of the orifice due to the aneurismatic process or to pressure from without from an aneurism, mediastinal tumor, etc. The pulsus differens can therefore be of value in the diagnosis of aortic aneurism, only so far as it shows an anomaly of the subclavian or of the aortic wall in the neighborhood of the origin of the great vessels. That the narrowing is at the orifice is shown with moderate certainty if the subclavian pulse shows the characteristic alteration in which the carotid on the same side also takes part. As regards the apparent delay in the transmission of the pulse-wave on the affected side, a comparative study of the sphygmogram of the two radial arteries shows that the starting-points of the two curves are coincident, but that of the stenosed artery shows a more or less diagonally inclined line of ascent, while that of the normal vessel is very nearly perpendicular, and therefore sooner reaches its apex. It is this characteristic which gives to the palpating finger the impression of delay on the affected side.

#### THE CONDITION OF THE LEFT VENTRICLE IN MITRAL STENOSIS.<sup>9</sup>

Lehartz has arrived at the conclusion that a concentric atrophy of the left ventricle in cases of mitral stenosis is rather the exception than the rule, and that the conditions necessary for compensation are far more often present than is ordinarily supposed. During the past few years he has had five women with that lesion under his care who were able to perform their household duties in a manner which admitted no doubt of the presence of compensatory changes. His belief was still further strengthened by the study of the records of the autopsies of ninety-eight cases. Leaving out of account those in which the conditions might have been altered by other cardiac lesions thirty-four cases remain, in eleven of which mitral stenosis alone existed, while in the others the amount of mitral incompetency was too small to exert any modifying influence. Of the thirty-four cases the left ventricle was distinctly atrophied in two, in three it was nine millimetres thick, in four it was normal (one centimetre in cross section), while in all the rest it was hypertrophied, varying in thickness from one to one and eight-tenths centimetre in thickness. Of the smaller series of eleven cases only one had a cross-section of less than one centimetre, the others varying from that to one and eight-tenths centimetres. As regards its capacity for contraction no definite can be given, but at all events in but few was it diminished, being more often of normal or increased. The condition necessary for

compensation are found in the hypertrophy of the right ventricle and left auricle and according to the recent investigations of Frey and Kiehl also in the suction power of the left ventricle, conditions which are present in a large number of cases but which are easily disturbed by too great demands upon the heart. In cases where sufficient muscular substance still remains in the right ventricle, he has seen surprising results follow the use of digitalis in strengthening its contractions and in allowing the left ventricle more time to fill, while by favoring the development of hypertrophy it increases its suction power.

#### THE RAPID HEART.<sup>10</sup>

In the annual oration before the Medical Society of London, Sansom analyzes seventy-five cases of rapid heart coming under his immediate observation, in which the condition had existed for comparatively protracted periods, and was apparently independent of organic cardiac lesions. These he has divided into two categories, (1) those unassociated with the cardinal signs of exophthalmic goitre, or, as he prefers to call it, cardio-vaso-motor disease, and (2) those in which such an association was more or less well-marked. Forty-six cases (16 men, 30 women) are included in the first division, twenty-nine (5 men, 24 women) in the second. As a result he considers the evidence adduced sufficient to justify the following proposition: In the first place it seems in the highest degree probable that the conditions in the two classes of cases are closely allied, in view of their etiology, consequences and associations. In both there is strong evidence of the initiating influence of psychical or physical overstrain or of both these causes combined, whilst in both also the conditions may develop without such initiating cause. In both, also, organic disease of the heart may be, although exceptionally, present, but there seems to be no good evidence to suggest that such structural disease, whether inflammatory or degenerative, is protopathic or even initiated at a comparatively early period of the malady. On the other hand, there is much to show that it is secondary to the nervous implication. It is clear that the impairment of the myocardium occasioning dilatation of the cavities may be temporary only in some instances. He does not think that cases of rapid heart should be looked upon as *formes frustes* of Graves's disease, but rather that cases of the latter should be regarded as *formes étendues* of the former, the differences between them being differences of extent as regards nervous implication rather than differences of intensity. In certain cases where the cardiac rapidity is the only evidence of circulatory disturbance the danger to life is extreme.

The signs of more extensive involvement of the nervous system are found in disturbance of the vaso-motor conditions of the great arteries of the neck whereby these manifest obvious and perhaps painful throbbings, of the thyroid arteries which may present dilatations and bulging, and also in the post-orbital, with perhaps such disturbance of nutrition as to lead to accumulation of a superabundance of fat. The irregularity noted in some of the cases seems to point to a further nerve involvement. He has evidence to show that an irregularity similar to that present in some cases of Graves's disease may occur without abnormal rapidity and without any other sign of cardio-vaso-motor affection. Concurrently with any of the signs

<sup>8</sup> *Proc. Roy. Soc. Med. & Nat. Hist.*, 1890, vol. x.

<sup>9</sup> *Ann. N. Y. Acad. Med.*, 1890, No. 2.

<sup>10</sup> *Lancet*, May 10, 1890.

mentioned or with all there may be an implication of the motor area leading to muscular tremors, and in some cases also impairment of the powers of the mind.

In the less severe cases medicinal treatment has proved of great value, but in the more severe forms drugs have seemed useless, notably digitalis and the heart tonics generally. The application of the continuous galvanic current to the great nerves of the neck has proved to be of value.

## Clinical Department.

### OBSERVATIONS ON TUBERCULOSIS OF THE KIDNEY, WITH A REPORT OF CASES.

BY WILLIAM H. PRESCOTT, M.D., AND JOEL E. GOLDFHWAIT, M.D.

THE following cases present some of the forms in which tuberculosis of the kidney manifests itself, and inasmuch as very little has been written upon this subject, a detailed report of these cases is deemed advisable. With the exception of Case II, they occurred in the wards of the Boston City Hospital, and we are indebted to the gentlemen, in whose services they were, for permission to report them in connection with this paper.

The first case is nearly typical in all its aspects, while the second case, of which there is but a brief report, due to the lack of accurate notes, presents the cardinal symptoms, and is of interest from the fact that a calculus was found in the pelvis of the diseased kidney. The similarity between the first and third cases will be seen at once, except for the contraction of the thigh in the latter case, evidently due to irritation of the psoas muscle; a condition which the writers have not found mentioned before in connection with this disease. The fourth case is modified by the presence of an old hip-joint disease, which renders the clinical history of less value, and makes the diagnosis the more difficult.

In studying these cases, one of the things which attracted attention has been the irregular condition of the urine; at one time cloudy, or even bloody, and again, often in a few hours, clear and quite normal in appearance. This symptom was present in all of the cases, and seems to be of more diagnostic importance than is usually considered.

Another interesting fact is that the temperature in the first and two last cases (no record of the temperature was to be obtained in the second case) was subnormal, in spite of the fact that there were quite extensive collections of pus in or about the affected kidneys. In the first case there was fully one-half a pint of pus, at the autopsy, on section of the kidney.

The position of the tumor is not constant; in the first case it could be seen and felt most plainly in front, while in the last case it was situated in the lumbar region.

CASE I. G. C., forty-one years of age, entered the Boston City Hospital, October 3, 1890, in the service of Dr. Geo. W. Gay. He was born and lived the greater part of his life in the State of Maine. In the early part of his career he was actively engaged in the ice business, but for the past two years he has been unable to do any heavy work, and during the last two or three months he has spent the greater part of the time in bed.

The patient did service in the Civil War, and while

before Petersburg received some injury to his left side, by falling into a ditch, from which he was some time in recovering. The injury, as far as can be made out, was a severe contusion of the left side, below the ribs.

The family history is good, and the patient has been a man of temperate habits, and denies ever having had any venereal disease. About two years ago he had an attack of typhoid fever, and since this sickness has "never seen a well day." He has not been as strong as previously, and has had a bunch in the left side, which has annoyed him considerably. This tumor was first noticed while convalescing from the fever, and when first discovered was about the size of a hen's egg. It has been present all the time, and has gradually increased in size until six months ago, since then no change has been noticed. The pain, which has not been excessive, has been of a dull, aching character.

One year ago the right testicle swelled to the size of "two fists," but this subsided after "strapping" the scrotum, and since then this testicle has been smaller than the other. Since the first swelling there has been no pain referred to this region. Micturition has been quite frequent, the urine at times being quite clear, while at other times, often in the same day, it has been thick and dark colored, even bloody. All sexual desire or power has been wanting during the last six months. The bowels have always been constipated until ten weeks ago, and since that time there has been a persistent diarrhoea. There has been some blood in the dejections, supposed to come from hemorrhoids. One month ago he was "jaundiced." He has not vomited, except once, ten days ago, which was immediately after eating, and the vomitus consisted of undigested food. There has been great thirst; and during the past five months there has been a marked loss of flesh and strength.

*Physical Examination.*—Patient is a man of average height, much emaciated; color, pale and sallow; skin, dry and rough. Temperature, 97.8°; pulse, 70. The lungs were normal. The cardiac impulse was weak, but otherwise the heart was normal. The abdomen was not distended. In the left side was a tumor about the size of a child's head, which extended under the free borders of the ribs, downwards to the crest of the ilium, and nearly to the median line in front. It was not painful to palpation, and the surface was smooth. The mass as a whole was quite firm, but on bimanual palpation, front and back, there was at least a suspicion of fluctuation. The mass itself was flat on percussion, but there was tympanitic resonance along the free margin of the ribs. The liver was normal in size. The right testicle was atrophied, and at its lower end was a small, hard nodule about the size of a hickory nut. The left testicle was normal to the feel. The urethra was very sensitive, but there were no strictures, a sound passing easily into the bladder. On rectal examination, the prostate was of nearly the normal size, but quite sensitive; and on the posterior bladder wall, on the left side, was a slight, irregular swelling, which was very painful to the touch, and which from its position and feel was supposed to be the enlarged seminal vesicle. (This is of interest, because at the autopsy it proved to be a mass of fibrous adhesions, by which a coil of the sigmoid flexure was attached to the posterior bladder wall.) There were no hemorrhoids. The urine, which was examined by Dr. Woods, was pale in color; specific gravity, 1.012; alkaline; albumen, one quarter per cent.; no sugar.

Sediment consisted chiefly of pus, singly or in clumps, a little blood, with an excess of cells like those from the prostatic region of the bladder, and there were a few triple phosphate crystals.

For the first four days after entering the hospital the patient was comfortable, except for the diarrhoea and the general weakness. On the fifth day he had a very sharp attack of pain referred to the abdomen, which was more severe than he had had at any time during his sickness. After this the patient sank into a state of collapse, and died two days later.

**Autopsy.**—The left kidney was enlarged to about the size of a cocoanut, and was made up of numerous cavities, varying in size from a filbert to an English walnut, which had shaggy walls, and were filled with a thick cheesy pus. Between the cavities, the outlines of which were eroded, was an increased amount of fibrous tissue. The ureter coming from this mass was thickened and enlarged to nearly the size of a lead pencil. The mucous membrane was infected, and the lumen obliterated at about the point where it descended into the true pelvis. The right kidney was a little larger than normal, and showed the amyloid reaction to iodine at the seat of the glomeruli. The pelvis was somewhat dilated. The bladder mucous membrane was infected, but no ulcerations were found. In the prostate were several small cavities with shaggy walls filled with pus. The right epididymitis was replaced by a cavity the size of a filbert not also filled with thick pus. The liver presented nothing abnormal. The spleen was enlarged to twice the normal size, of increased density, and showed a well-marked amyloid reaction to iodine. In the large intestine there were several ulcerations, extending as far as the ilio cecal valve, and in the upper portion of the rectum there was one about an inch long, which had perforated into the peritoneal cavity. The edges of this ulcer were irregular and sloughing. There was evidence of a slight pelvic peritonitis. There was no enlargement of the mesenteric glands. The remaining viscera presented no pathological appearances.

**Pathological diagnosis:** Primary tuberculosis of the left kidney; tubercular prostatitis; tubercular epididymitis; tubercular ulcerations of the large intestine, with perforation of rectum; amyloid degeneration of spleen and of right kidney.

The specimens were examined by Dr. W. W. Gannett.

**CASE II.** This case, who was a patient in the practice of Dr. J. Foster Bush, had been sick about eighteen months with symptoms of general malaise and frequent micturition, the urine being loaded with pus. At the end of the time a perinephritic abscess formed, which was opened three times within a few weeks; and several ounces of pus removed at each aspiration, with only temporary relief. Then an opening was made and a drainage tube inserted. The patient rallied from the operation, but died in two weeks of exhaustion.

At the autopsy all of the organs were in good condition except the right kidney, which was completely disorganized and the pelvis contained a calculus. Microscopic examination showed the bacilli of tuberculosis. The specimens were examined by Dr. W. W. Gannett.

**CASE III.** F. W., twenty years of age, entered the Boston City Hospital May 20, 1887, in the service of Dr. Abner Peck, with the following history:

"He was well up to two years ago when he began to have frequent micturition, having to get up two or three times every night. He noticed nothing further until August, 1886, when he passed some blood once, and occasionally had some slight pain after micturition. Last November he had typhoid (?) fever, although at the time he had no headache, nose-bleed or diarrhoea. He remained in bed three weeks, and then was able to be up and about for a few days; at this time he began to complain of pain in the left side of his abdomen. During the three weeks he was in bed his urine was very foul and thick, and contained much blood; micturition every twenty minutes; the left leg began to draw up; there was much pain over left anterior superior spine of the ilium. No swelling was noticed anywhere; and there was no pain in his back. These symptoms continued five weeks; and then, under ether, an incision was made in his left lumbar region, and about three pints of foul pus were evacuated. From the wound thus made there has been a discharge of foul pus ever since. He has had little pain and has lost much flesh and strength. He had frequent micturition and some diarrhoea. His appetite is good and he has had no cough. No feces have ever come from the wound, but some bubbles of gas were noticed when the wound was syringed. The family history is negative."

**Physical Examination.**—Fairly well developed but very much emaciated. The abdomen is not distended. The back is rigid and the left thigh is flexed upon the abdomen at an angle of 120°. On the left side, about two inches above crest of ilium there is a granulating surface about two by one and a half inches in superficial area, in the centre of which is a sinus (holding a drainage-tube) extending downward and backward from which there is a profuse discharge. Nothing was found on rectal examination except a sense of thickening and resistance in the region of the bladder. Urine pale, neutral; specific gravity 1,006; albumen one-eighth per cent.; abundant sediment, chiefly pus; no casts. The examination of the chest was negative.

The next evening there was a severe hemorrhage from the sinus (by estimate one pint) which was finally checked by packing the sinus with sponges.

The patient lived one week after entrance, and during this time, the discharge from the wound continued foul, without urinary odor. There was a slight diarrhoea and the urine at times was nearly clear, while again it was nearly solid pus.

The autopsy was performed by Dr. W. W. Gannett.

The left kidney was almost completely disorganized. The small amount of renal tissue which remained, together with the fibrous capsule, formed the wall of a sac, about the ordinary size of the kidney, which was filled with pus and debris. This on being laid open showed six or eight ulcers deeply excavated with raised and scalloped edges arranged as if originally they represented the calices of the pelvis. This sac communicated with a cavity in the cellular tissue, posterior to the peritoneum, extending from the diaphragm down into the pelvis, and having shaggy and gangrenous walls. The left ureter was free, of the usual size, while its mucous membrane was rough and cheesy looking, and showed some very small nodules. The right kidney was increased about one-half in size. One of the pyramids was represented by a deeply excavated ulcer similar to those in the left kidney and

the renal substance about this contained numerous small grayish nodules. The bladder was distended, and the mucous membrane showed some slight loss of substance. The spleen, liver and right kidney showed well-marked amyloid reaction to iodine. The descending colon was adherent to the wall of the abscess cavity, but there was no evidence of any communication between the two. The lungs showed signs of beginning tuberculosis, but otherwise the remaining viscera were not remarkable. The vertebral column and left hip-joint were examined with negative results.

**Pathological diagnosis:** Primary tuberculosis of the left kidney and ureter, with retro-peritoneal abscess; tuberculosis of the right kidney; tuberculosis of the lungs; amyloid degeneration of the spleen, liver and right kidney.

**CASE IV.** J. O'M., forty-five years of age, entered the Boston City Hospital August 3, 1885, in the service of Dr. E. H. Bradford. His history is very long and indefinite, and much has been omitted, as it would simply be confusing and of no particular value, but condensed it is as follows: When three years of age he had disease of the right hip-joint, and has been lame ever since. He had syphilis twenty-four years ago. The present trouble began about two months ago, the first symptoms being an occasional attack of vomiting, frequent micturition, and pain referred to the back and to the right hip. After that time his general condition grew steadily worse; the pain became more severe and was of a sharp, shooting character, starting in the back and extending into the right side. The pain was worse at night. Just previous to entrance some tenderness in the right lumbar region was noticed. The urine varied in character; at times was clear, and at other times contained much pus. There was quite a persistent diarrhoea—together with a marked loss of flesh and strength.

On entrance to the hospital the patient was very weak and extremely emaciated. There was evidence of an old hip disease on the right side with dislocation of the femur upwards and backwards. Pressure over the right iliac fossa caused pain as did also pressure in the axillary line just below the ribs. No tumor was to be felt in front, but in the right lumbar region there was a slight prominence which was flat on percussion. There were a few moist râles with diminished respiration at the base of the right lung. There were also two perineal fistulae. The urine contained much pus.

During the patient's stay in the hospital previous to operation, he steadily grew weaker; the swelling in the right lumbar region gradually increased, and the pain was quite severe, requiring morphia for relief.

Ten days after entrance Dr. Bradford operated. An incision was made over the swelling on the right side just external to the quadratus lumborum muscle. A trocar was then passed through this wound, and it came upon some thick, cheesy pus. This opening was dilated, and a few drachms of similar material were evacuated. (The renal substance was recognized in the exposed tissues.) Because of the very weak condition of the patient no farther exploration was made. He was freely stimulated, but failed to respond, and sank into a state of collapse and died the next morning.

The autopsy was performed by Dr. W. W. Gannett. The site of the right kidney was occupied by a mass of dense connective tissue, in which were to be seen

on section a few isolated masses of renal substance. In these portions were cavities, which varied in size from a pea to a walnut, and were filled with cheesy material. The outlines were crenated, and the outer borders showed a translucent line about two millimetres in width, which separated the cheesy material from the renal substance. In the connective tissue already mentioned were several similar cavities. The right ureter could be followed up to a cheesy cavity the size of a walnut, which probably represented the pelvis of the kidney, and it was at the junction of the ureter with this cavity that the opening made at the operation ended. In the right half of the pelvis, along the ilium and following up across the ureter, was a mass of dense fibrous tissue. The bladder showed nothing abnormal. There was a compensatory hypertrophy of the left kidney. The liver, spleen and the mucous membrane of the intestine showed a well-marked amyloid reaction to iodine. The right acetabulum had wholly disappeared, the femur being attached to the pelvis by fibrous bands, and the point of junction of the two bones showed a roughened surface covered with connective tissue. The remaining organs showed nothing remarkable except that in the upper lobe of the right lung there was a group of grayish translucent nodules; the whole about the size of a filbert.

**Pathological diagnosis:** Chronic tuberculosis of the right kidney, with chronic fibrous perinephritis; recent circumscribed tuberculosis of the right lung; amyloid degeneration of the liver, spleen and intestines.

#### A CASE OF NEPHROLITHOTOMY (FOLLOWING NEPHRECTOMY) FOR TOTAL SUPPRESSION OF THE URINE LASTING FIVE DAYS: RECOVERY.<sup>1</sup>

BY R. CLEMENT LUCAS, B.S., F.R.C.S.,  
*Surgeon to Guy's Hospital and to the Evelina Hospital for Children.*

This case was mentioned by the editors of the medical journals at the date of the operation, in 1885, as a case of exceptional interest; but the details of the case have never been before published, nor has the patient, or her kidney, or the stone which caused suppression ever been exhibited before. The author had delayed publishing it because those to whom he mentioned it, whilst applauding the attempt to save a life on the extreme verge of dissolution, threw the coldest doubt upon the patient's future, maintaining that even if she recovered from the immediate effects her life must be a short and painful one; that the one remaining kidney, having been opened and drained, would rapidly degenerate, or another stone would quickly form and bring about a final catastrophe. After the lapse of five years the author thought he might be acquitted of any attempt to claim an incomplete success. The patient is still living and enjoying the best of health, and a freedom from pain, discomfort, and hæmaturia, which, for seventeen years before her right kidney was removed, were almost constantly present. The operation for total suppression of urine was one that the author had long considered justifiable, and he had on more than one occasion previously publicly advocated its performance.

The patient had been under the care of Mr. F. D.

<sup>1</sup> Abstract of paper read on Tuesday, January 13, 1891, before the Royal Medical and Chirurgical Society, London.

Atkins, of Sutton, Surrey, to whom much credit is due, both for the original diagnosis and for the promptitude with which he acted when total suppression occurred.

E. F., age thirty-seven, was first admitted into Guy's Hospital on June 22, 1885. There was a strong family history of consumption. For seventeen years she had suffered from hæmaturia at intervals, and for nine or ten years this had been accompanied with pain on the right side of the abdomen, and for seven years a tumor diagnosed as a floating kidney had been felt on this side. On July 14th the right kidney was removed by lumbar incision. It was a mere shell containing masses of stone, and weighing twenty-one ounces. The wound healed completely, and she left the hospital convalescent on August 10th, just within a month of the operation. All went well for three months. She had returned to her household duties, was free from pain and hæmaturia, and much satisfied with the result of the operation.

On Sunday morning, October 21, 1885, she was suddenly seized, between seven and eight o'clock, with most violent agonizing pain in her back and left loin. The pain passed through the loin to the front of the abdomen and groin. About eight o'clock she passed a little urine, but from that time all secretion stopped. Vomiting commenced about half-past eight on the same morning, and was continued at intervals and whenever anything was taken. Mr. Atkins was called to see her, and found the bladder empty. Vomiting and anuria continued throughout Sunday, Monday, and Tuesday.

On Tuesday Mr. Lucas met Mr. Atkins in consultation, and advised operation.

The symptoms continued without cessation on Wednesday, when she was brought to London, but Mr. Lucas's medical colleagues still advised him to postpone operation till a further trial had been given to diuretics, and in deference to their opinion he waited another day. On the afternoon of Thursday, the fifth day of anuria, the patient became drowsy and weaker, so that it was difficult to rouse her to obtain answers to questions. Her pulse was weak, her temperature 99°, and she had become less sensitive to pain and indifferent to what was passing around. Ether was given, and Mr. Lucas cut down on her remaining kidney and discovered a conical stone acting as a ball-valve to the top of the ureter. The stone was rather more than three quarters of an inch in length, and from three eighths to five eighths in diameter. Urine began to drop away out of the wound as soon as the pelvis of the kidney was opened, but the pelvis was not found much dilated.

The patient recovered well from the anæsthetic, and was sick only after the operation. For twelve days no urine was passed by the wound in the loin. Then an ounce and a half was passed with great pain from the bladder, and the quantity gradually increased.

After the nineteenth day all the urine was passed naturally. The wound ran an aëptic course, and the patient's temperature scarcely rose above normal. Healing was complete ten weeks after the operation. During the last five years she has been employed in her child duties, and has enjoyed good health.

The patient was satisfied, together with her right kidney, which was removed, and the stone removed from the left kidney for total suppression of urine.

## REMOVAL OF LARGE CALCULI, FIRST FROM ONE KIDNEY AND AFTERWARDS FROM THE OTHER; DEATH FROM HÆMORRHAGE.

BY RICKMAN J. GODLEE, M.S.

The patient was a gentleman, aged thirty-seven, who first complained of renal symptoms in 1886. In the autumn of 1888 a diagnosis of left renal calculus and left pyelitis was made, but mischief on the right side was suspected also.

In November, 1888, a large quantity of stone, uric acid and phosphatic, was removed from the left kidney. The patient made a rapid recovery, but the closure of the wound was not permanent, and after several febrile attacks it was found best for the patient to wear a plug permanently in the fistula, to prevent periodical accumulations of pus and urine in the kidney. At one time the ureter became completely blocked, and an operation was undertaken to remove a stone which was supposed to be obstructing it. None was found, but the ureter became again patent after the operation, and the state of the kidney very much improved.

The patient now became convinced that he had stone in the right kidney. The risks of an operation were explained, but he was recommended to submit to it, and on November 19, 1890, large masses of uric-acid stone were removed. No bleeding followed the first incision into the kidney, but the laceration that was caused by the removal of the stones gave rise to very free venous hæmorrhage, which was easily controlled by pressure. At the completion of the operation there was little or no bleeding, but it was thought safer to plug the pelvis of the kidney. The patient remained in fair condition for an hour and a half after the operation, and then suddenly died, as the result of fresh hæmorrhage from the kidney.

The rarity of the accident is dwelt upon, and attempts are made to suggest means of combating it if it arise.

## TUBERCULOSIS IN CHILDREN: SOME PHENOMENA ATTENDING INITIAL INJECTIONS WITH KOCH'S FLUID.

CASES IN BERLIN IN THE PRIVATE HOSPITAL OF DR. LEVY.

BY J. WARREN ACHORS, M.D.

For at least six weeks prior to the appearance of Professor Koch's announcement, in the *Deutsche Medicinische Wochenschrift*, November 13th, of the details of his treatment for tuberculosis, patients suffering from phthisis and glandular tuberculosis had been undergoing experimental injections at Dr. Levy's private hospital, Prenslauer Strasse, Berlin, under the immediate supervision of Professor Koch himself. After that date the entire hospital was given up to cases selected for treatment by the injections.

Among the cases treated there were several children, notes of which I took whilst serving as interne in the hospital. These notes, though brief and somewhat incomplete, are here presented in the hope that they will be found sufficiently instructive to warrant perusal, the presentation being based upon the appearance of certain phenomena during the initial injection.

CASE I. Supposed diphtheria, in a healthy-looking boy ten years of age, the patches appearing, the size of the

<sup>1</sup> Abstract of paper read on Tuesday, January 13, 1891, before the Royal Medical and Chirurgical Society, London.

palm of the hand, on the inner aspects of the calves of both legs, and they looked quite like lupus.

Given, November 23d, an injection of half a milligramme of a one per cent. solution of fluid. No reaction followed; doubted if lupus.

Given, November 25th, an injection of one milligramme. Twenty-four hours later, no reaction having followed the second injection, the case was dismissed. The diagnostic efficiency of the lymph is here well shown.

CASE II. Lupus, in a boy of eight years. A poor, scrawny-looking little fellow he was, with big freckles spattered promiscuously all over his face, and a big lupus patch on the left side of his head, involving the ear.

Given, November 23d, an injection of half a milligramme of a one per cent. solution. Four hours after the giving of the fluid, an exanthematous rash showed all over his body, in appearance like that of scarlatina; and twelve hours after, the temperature reading was  $104\frac{1}{2}^{\circ}$ , with pulse at 156.

November 28th, the third injection was made, half a milligramme, as previously, being used. The temperature went up to  $104\frac{1}{2}^{\circ}$ , pulse 112, no rash.

The unusual feature in this case was the appearance of the exanthematous rash.

CASE III. Abscess, in a girl four years of age, following scarlet fever; located in the right groin; incised; but still she continued having a daily fever of  $100^{\circ}+$ . Tuberculosis suspected, retained pus suspected.

Given, November 22d, half a milligramme of a one per cent. solution of fluid. No reaction followed. The aspirator was then used, and a pocket of pus evacuated in the right iliac fossa near the vermiform appendix; when, the fever subsiding, the child was sent home.

In this case, tuberculosis as the cause of the fever was excluded, and the suspicion of retained pus strengthened and verified.

CASE IV. Abscess, in a boy two and one-quarter years of age; also suffering with tuberculous caries of the phalanges (spina ventosa).

Given, November 22d, an injection of half a milligramme. In eight and one-half hours his temperature reading was  $104\frac{1}{2}^{\circ}$ , pulse 140. Twenty-four hours after, the abscess under the ear broke, and there was superficial sloughing also of the points over the bone enlargements of the fingers.

CASE V. Morbus coxae of the left hip, in a boy five years of age.

Given, November 22d, half a milligramme of a one per cent. solution. In six hours he had a temperature of  $101^{\circ}$ , pulse 136. In eight hours an abscess began to point between two sinuses in the diseased hip, directly over the great trochanter, and the sinuses exuded a thickened pus.

November 28th, after three injections, there was fluctuation in the swelling over the trochanter, and its incision was followed by a free discharge of laudable pus.

In these two cases the direct action of the material caused spontaneous discharge of one abscess and the formation of another from retained purulent matter.

CASE VI. Morbus coxae of the left hip, in a boy the age of the last-named; there being no sinuses in this instance, but swelling, induration, immobility and tenderness.

The injections were followed by rapid softening of

the parts, the skin taking on a softened natural feel, the induration and rigidity disappearing with the return of mobility. The tenderness disappeared almost at once, with the restoration to normal of the probably tuberculous synovial membrane. The helpful value of the lymph in determining the non-existence of caries or necrosis of the head of the femur is here presented.

CASE VII. Tuberculous glands of the right side of the neck, in a young woman, twenty-five years of age.

She was admitted to Levy's clinic November 8th, and received, between this and November 25th, four injections of fluid, in each instance the same in amount, either one or two milligrammes of a one per cent. solution. The highest temperature readings for the four inoculations were: for the first,  $101^{\circ}$  four hours after the giving; for the second,  $104\frac{1}{2}^{\circ}$  six hours after; for the third,  $104\frac{1}{2}^{\circ}$  eight hours after; and for the fourth,  $104\frac{3}{4}^{\circ}$  nine hours after.

This case points us to the fact that the temperature does not *always* progressively diminish, as it is wont to do as the treatment proceeds. In this case the enlarged glands became smaller and movable, the skin over them softer and movable, the redness entirely going out.

The disappearance of the induration in all cases, especially in the last two named, was marked, the direct action of the injection upon the indurated tissues causing the exudate to disappear rapidly into the circulation.

The cases of hip disease contrast well, the precipitate action of the fluid upon caseated tuberculous tissues producing abscess in the first instance; while in the second, the tubercles being not so far advanced, no such reaction is observed.

The lupus cases exhibited during the reaction of the drug, aside from temperatures, increased heart's action and respiration, the usual constitutional symptoms of nausea, headache and stupor, with pain at the site of the disease; the local signs being great swelling of the affected area, attended with redness and exudation of serum, a soft marginal film showing in the later stages of each reaction, followed by brown scabbing and exfoliation, as the healthier skin encroached upon the diseased tissues from all sides.

The constitutional symptoms and the local reactions in the other cases mentioned, aside from what has been said of them in particular, were in the main, similar to the above recital. In all cases the diet was simple and nutritious, and in all affected by the fluid there was improvement from its use.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, Monday, November 21, 1890. DR. W. L. RICHARDSON in the chair.

DR. F. I. KNIGHT reported two cases of

#### SUSPECTED ANEURISM OF THE AORTA,<sup>1</sup>

in one of which autopsy confirmed the diagnosis, and in the other failed to do so.

<sup>1</sup> Publication deferred.

DR. J. C. WARREN read a paper on

THE PARASITIC ORIGIN OF CANCER.<sup>2</sup>

DR. J. C. WHITE: The relations of these bodies, if we accept them as the cause of the tissue changes in the diseases in which they are found, to cancer are not very clear. If we take the disease in which these bodies were first studied, especially those to which Dr. Warren alludes, the two cases which occurred in Paris year before last, and the two which occurred here under my observation; if we believe that those bodies which are found in the mouths of the sebaceous glands are parasites, are coccidial bodies, it is evident that they may exist in an individual case for twenty-five or thirty years without producing cancer. In Darier's cases the longest record of the existence of the disease was nine years, and in that case there was no evidence of any epithelial transformation. In my case, the latter's, — there were outgrowths, from one-half to three-fourths of an inch in elevation, enormous masses consisting of epithelial tissue, none of which had given any evidence whatever of any transformation into epithelioma. And in all the four cases no such transformation was seen; so that here, at any rate, is the zoöperm disease which is best recognized and has been best studied, in which after many years' existence there is no tendency to the formation of cancer. If we take Paget's disease, and accept Dr. Wickham's views as established: that the bodies there are also coccidia, although not the same species as found in the affection of which the photographs are being passed, there we find that the disease eventuates in the great proportion of cases in epithelioma. At any rate, it is fair to say that the disease attracts attention especially when it has become an epithelioma; but it is also well known that it may exist in the form of a dermatitis for an indefinite period of time, ten or twelve years, without any epithelioma being formed in connection with the case. So that even in that disease these bodies can be present that length of time, assuming Wickham to be correct in his opinion that the disease begins with their presence and is always the result of their presence. Now Wickham makes the statement that these parasites are undoubtedly the cause of the cancer, and Darier supports him in this view. Inasmuch as we know that prolonged dermatitis, due to a great many causes, may eventuate in epithelioma, a well-recognized pathological law in diseased tissue, changes of the skin which are in no way parasitic, in lupus and other forms of long continued excitement of the skin, it is not apparent, it seems to me, that the epithelioma transformation in so-called Paget's disease is necessarily the result of the presence of these bodies at all. It seems to me that the clinical evidence is against that deduction. Granting long continued inflammatory processes, as in lupus and ulcers which are likely to be converted into cancer, and recognizing the fact that the coccidial bodies may exist from ten to thirty years without producing the disease, it seems to me that it is a fair attribution to the subsequent establishment of carcinoma in Paget's disease to the long continued dermatitis. It appears to me that the burden of proof rests with those who maintain that these bodies are parasites, and that the parasites are the cause of cancer, to show in what way they become the cause of cancer after existing in the cutaneous tissue for such long periods of time without producing it.

<sup>2</sup> See page 56 of the January

With regard to molluscum contagiosum as a possible instance of disease produced by these bodies: The peculiar cells in the affection have long been the subject of dispute among histologists and dermatologists as to their true nature; and some of the modern French histologists, who have been the earliest to accept the coccidial nature of the bodies found in Paget's disease and in our keratosis follicularis, or vegetating zoöperm disease, as they call it, deny that the corpuscles in molluscum contagiosum are coccidial in character. Almost every possible explanation has been offered in the past twenty years as to their nature, but I do not think that anything very positive has ever been determined about them. These bodies at least do not readily undergo transformation into cancer. It is only in very rare instances indeed that such changes have taken place. Although there is good clinical evidence that they are in exceptional cases contagious, it does not follow on that account that they are necessarily parasitic in their nature.

It might be supposed that we might determine something definite with regard to the so-called animal nature of these bodies by the action of parasiticides upon them. So far as I know there is no animal parasite which inhabits the tissues of man which may not be destroyed by the action of substances called parasiticides. I have had opportunity for a year and a half of studying the action of parasiticides upon my second case, the daughter of the patient, whose photographs are exhibited. She has been under constant treatment for that period, and the use of every parasiticide of the most powerful character has failed to produce the slightest impression upon the development and continuance of these lesions. And the same results have followed the use of parasiticides in this same disease in France; so that that test, although its results are negative in character, at least has established the fact that here is one so-called animal parasite upon man which does not seem to be influenced by substances of the most powerful destructive action upon all other animals. The molluscum epitheliale or contagiosum is now always treated by myself by sulphur ointment, and in the great majority of cases successfully. That I do not offer as an instance of the action of sulphur on coccidial growths, but to show how differently that growth acts under parasiticides from these other diseases which are regarded as parasitic.

To return to Paget's disease. That begins as an inflammatory process, and is generally mistaken at first for chronic eczema of the nipple and the tissues surrounding it; and Paget himself admits that it is impossible in some cases to determine, except with the microscope, whether we are dealing with eczema of the part or with this peculiar disease; and there is no doubt that many cases of chronic persistent eczema of this part might pass into subsequent epitheliomatous disease if not cured by proper treatment, such as is used in eczema. I have in a few instances, because the disease is of rare occurrence, seen cases of clinically well-defined Paget's disease of the nipple, not established to be epitheliomatous by microscopic examination, yield to treatment addressed to the affection as if it were an eczema; and I have no doubt that pure and simple eczema of the nipple, if continued for many years, would be capable of transforming itself into an epitheliomatous growth without the presence or the intermediary action of any such bodies as these.

DR. WHITNEY: I have but little to add from per-

sonal experience. I have looked at cancer of the breast very often, with the hope of finding these bodies there; but as yet I have failed. As regards the association of these zoöspores or bodies with epithelioma, it seems certain almost that they coexist, but I quite agree with Dr. White that as yet they cannot be considered as the cause of the disease. There are several steps yet wanting that must be first completed, namely, their cultivation outside of the body, and the production of the disease by the inoculation of the pure culture. From the evidence which we have at present there are one or two points which tend to show their association rather than their causative relation. One is, that in cancer we find almost a definite structure. The line between the true production of gland tissue and what is called cancer is at times hard to distinguish microscopically, and we find many cases which, histologically, we are in doubt whether to call adenomatous growth or true cancer. As far as we know the action of other low organisms, any tissue which can be produced by them is not much higher than the so-called irritation tissue. Tissue produced by simple chemical irritation consists principally of the indifferent round cells which reach a greater or less state of development and then undergo various forms of degeneration. All of this is well known in the affections of tubercle, syphilis, glanders and the like. We can imagine that an animal or vegetable parasite could produce a tissue of this sort to reach a certain stage of development, but that an irritation could produce an almost perfect reproduction of glandular growth, from *a priori* reasoning, is hardly credible. Of course, no one would be so bold as to say it was impossible; but reasoning from all other analogy the burden of proof, it seems, must rest with those who say it does.

There is another point: as yet, in the specimens of zoöspore disease, I have never seen any tendency to the production of epithelium, and we should require some sort of demonstration of a formative action or a tendency in that direction. It seems, however, to be rather of destructive than constructive character. From the evidence that we have at present these bodies can hardly be accepted as the cause of the disease. I think the association is highly probable.

DR. BOWEN: There are three affections of the skin, all characterized by pathological changes in the epithelial layer, which are regarded by some as caused by the action of different varieties of the sporozoa. These are the molluscum contagiosum, keratosis follicularis (*psorospermose folliculaire végétante*), and Paget's disease of the nipple.

In none of these affections has positive proof been offered, that the bodies present represent animal life. Only one thing is certain, and that is that in each of these affections, certain peculiar cell forms are constantly seen which offer a striking resemblance to the sporozoa, and especially to the coccidium oviforme found in the liver of the rabbit. This resemblance is, as I say, striking, and however sceptical one may be inclined to be, the hypothesis cannot justly be brushed aside until we are able to give a more satisfactory explanation of these appearances than has yet been offered.

In the three affections cited there is undoubtedly a proliferation of the epithelial elements, as is the case also in the cysts of the rabbit's liver caused by the oviform coccidium. It must be admitted, therefore,

that the cell bodies in question, whether or not they are forms of animal life, occur only, so far as has yet been observed, under conditions of proliferating epithelium.

What are the probabilities, in these three affections, that they are of psorospermic origin?

(1) Molluscum contagiosum. No doubt can now exist, from the constantly accumulating evidence, that these tumors are in some way transmissible, although the manner is still a secret. There is also no doubt, in my opinion, that they are to be classed under the epitheliomata, as Virchow long ago pointed out. The theory that the peculiar cell elements which compose them are altered sebaceous glands, is untenable. The work of Neisser, following the suggestion of Virchow and Klebs, has rendered it exceedingly probable that the tumor is composed of coccidia enclosed in cells, and that, hand in hand with their development, there is produced a hyperkeratosis of the epithelial elements. One who studies these forms carefully, and compares them with known varieties of coccidia is forced to the conclusion that the theory that these are animal parasites, is at least based upon a more solid foundation than any other that has attempted to explain their nature. Positive proof can only be reached by means of cultivation, which has thus far failed.

(2) Keratosis follicularis and Paget's disease may be grouped together. The cell bodies in these two affections bear a far closer resemblance to one another than to those seen in molluscum contagiosum. Paget's disease I have not had an opportunity of studying, and I draw my conclusions solely from the comprehensive work of Wickham, following Darier. Of keratosis follicularis, I have had an opportunity of seeing three cases, in two of which, those of Dr. White, I was enabled to study the lesions microscopically. It may be assumed, I think, that the bodies found in this disease are to be interpreted in the same way as those of Paget's disease, as they are found under similar histological conditions, and as they are morphologically so nearly alike. Are they coccidia? This question I am still unable to answer. An abundance of hardened material was at my disposal, but unfortunately, very little fresh material. I am now convinced that some of the bodies are enclosed in epithelial cells, a point that was not at first clear, and which I have not found easy to settle. There can be no question that in keratosis follicularis there is a very marked hyperkeratosis of the epithelial structures in each follicular lesion, and the name keratosis follicularis is therefore well chosen, even if positive proof is given that the cells are parasites. No success was obtained in attempts at cultivation, and an elective staining has not been found. Specimens hardened in Müller's or Flemming's fluid show the bodies more distinctly than those hardened in alcohol, on account of the contraction caused by the latter agent. We have as yet no evidence that either keratosis follicularis or Paget's disease of the nipple are transmissible, unlike molluscum contagiosum.

Lastly with regard to cancer. All microscopists have seen peculiar cell bodies in certain epitheliomata, and all those who have made comparison will admit that they often resemble forms of the sporozoa. They are also very similar in many instances to the psorosperm-like bodies in keratosis follicularis. Those who have suggested that they were animal organisms and the cause of the new growth, have pointed to an

analogy with the three cutaneous affections described, where there is also a proliferation of epithelium. In none of these affections, however, has their nature been fully proved. The affection that offers the most probability of being of psorospermic origin, is, in my opinion, molluscum contagiosum, and the appearances here found are not very similar to those seen in either keratosis follicularis, Paget's disease, or epithelioma. That cancer is an infectious disease, although not improvable, *a priori* has not been established. Hanau's experiments have shown that epithelioma may be inoculated from one rat to another, but Klebs, who has succeeded even in transferring cancer of the breast to animals, regard it as a mere transplantation, and in no sense an inoculation. The hyaline bodies found by Klebs in cancer, often contained in epithelial cells, are probably the same elements that have been considered by Thoma, Darier and others, as psorosperms, but the conclusions of Klebs are strongly adverse to their being parasites. On the other hand, the recent results of peculiar methods of staining, exhibit forms which it is difficult to regard as tissue changes. In other pathological conditions also, appearances may be occasionally seen which bear as strong a resemblance to psorosperms as do the bodies found in cancer. I have seen hyaline-looking bodies, sometimes nucleated, with contraction of the protoplasm, so that they seem to be encysted, in a case of verruca vulgaris, in two specimens of cutaneous horn, and lately in a condyloma acuminatum. This points more to the view that the cells are the product of pathological changes in the epithelium, than to the view that in each of these cases the cause is a psorosperm.

In conclusion, it seems to me probable that it will be proved that molluscum contagiosum is caused by coecidia. As to keratosis follicularis and Paget's disease, many things speak in favor of Darier's view, that they are psorospermic diseases; but until more evidence can be produced, judgment should be suspended. As to cancer, we have as yet little evidence of its parasitic origin; but, in default of any definite knowledge, the theory that some forms may be caused by sporozoa should be fairly considered until positively disproved.

Dr. J. J. JONES: The question is so important that, even in only repeating what has been said before, I would like to call attention to a few facts. It has not yet been shown that psorosperms occur in cancer, much less are the cause of it. There are numerous diseases in animals which we know are due to psorosperms; all of which are destructive, not constructive, like cancer. Klebs' work clearly shows that the so-called inoculation of cancer in rats is nothing more than a case of grafting, not of inoculation; that no one, either at autopsy or operation, has ever been known to be infected with cancer.

Dr. C. B. PORTER read a paper on

#### THE REMOVAL OF THE APPENDIX DURING A RE- MISSION IN CASES OF RECURRENT ATTACKS OF APPENDICITIS.

Dr. ELLIOT: It seems to me that the difficulty in diagnosis of which Dr. Porter has spoken, does not commonly occur, that the diagnosis is usually simple, and is not a real hindrance to operating in the class of cases. Nor do I think the danger great in recurrent attack; for the attack is generally not very severe,

but the invalidism resulting from them is, I am sure, often sufficient cause for operation. The best argument that I have heard against the operation is the difficulty of finding and removing an appendix tied down by very firm old adhesions. The question of operating in these cases is much the same as in cases of chronic salpingitis. The extent of invalidism, the occupation and circumstances of the patient, being the important factors. The same difficulties are met with in both operations. The same success will undoubtedly be obtained in the chronic cases, which at first thought seem so discouraging.

Dr. Elliot then reported the following case:

#### EXCISION OF VERMIFORM APPENDIX BETWEEN THE ATTACKS IN A CASE OF CHRONIC APPENDICITIS, THE APPENDIX BEING FOUND IN AN ILEO-CÆCAL FOSSA.<sup>1</sup>

The patient had been suffering for two years from attacks of appendicitis, recurring every month or six weeks, which became successively more severe, and which had permanently disabled her. At the operation the appendix was found imbedded in a fold of peritoneum, such as Treves describes as an ileo-cæcal fossa. The operation proved difficult, but the appendix was finally dug out of a mass of adhesions and removed in a lacerated condition.

Dr. Elliot then showed the appendix which he had removed and specimens of ileo-cæcal fossæ of various sizes and shapes.

The patient made a good recovery; and during the eight months which have elapsed since the operation, she has improved in general health, gained twenty to thirty pounds in weight, and has had none of the old attacks.

Dr. A. T. CABOT reported a

#### A CASE OF RELAPSING APPENDICITIS IN WHICH THE APPENDIX WAS REMOVED IN AN INTERVAL BE- TWEEN THE ATTACKS.<sup>2</sup>

Dr. M. H. RICHARDSON: In the discussion of this subject at Washington in the spring the feeling seemed to be rather against interfering in these cases. I think the paper of Dr. Porter and the remarks of Dr. Elliot and Dr. Cabot are all in advance, distinctly, of what was said and had been done up to that time. To Dr. Porter's paper I think hardly anything can be added. All the arguments for and against were shown very clearly. Although I have never had a suitable case I should certainly be in favor of removing the appendix in cases where the indication was such as Dr. Porter stated, and I think that is what we are all coming to in these cases.

Dr. WHITNEY: I should like to call attention to the pathological appearances in these appendices which have been removed. The first specimen represents a normal appendix; the second specimen is Dr. Porter's first case, which shows the enlargement and thickening of the organ very well; then his second specimen which also shows conditions almost identical with those of the first; finally, Dr. Cabot's specimen which shows certain microscopic differences from the other two. In both of Dr. Porter's specimens are represented changes especially to be referred to the muscular and serous coats, the mucous membrane being almost intact as far as can be seen microscopically. Both of the coats are very much thickened, especially the muscu-

<sup>1</sup> See page 64, Vol. XXIII, of the Journal.

<sup>2</sup> See page 31 of the Journal.

lar. In Dr. Cabot's case we have the same general thickening or gross appearances of the appendix, but the microscopic examination shows that there is not only this hypertrophy of the coats, but the mucous membrane has been destroyed. It is left intact only in little islets. We have what would be called a catarrhal appendicitis. The other two specimens present nothing of these evidences of inflammation, nothing beyond the hypertrophy of the muscular and serous coats. For the present I have ventured to make a distinction and call the one chronic appendicitis and the other chronic catarrhal appendicitis. I was very much interested in Dr. Porter's analysis of cases to find that as far as any careful examinations had been made, the same condition had been found as in these here. Many of them were spoken of as in a condition of hypertrophy of the muscular coat. In one or two the mucous membrane was intact, and only one or two represented any lesion of the mucous membrane of the appendix.

It is too early yet to make any very generalized statements on the subject, and I hope, from the specimens which have been kindly placed at my disposal, to be able to work up this subject of chronic appendicitis, and if possible to say what the histological examination shows. It would be a little early yet to formulate any idea as to what may cause these recurrences of pain in the interval. One might, for a working hypothesis, suggest that some catarrhal affection of the appendix had caused in its course an hypertrophy of the other coats of the intestine and especially of the muscular coat; and that these paroxysmal attacks may be something of the nature of tetanus, set up by little faecal particles or foreign bodies.

DR. R. H. FITZ: I think, in the list of cases that Dr. Porter has reported, there are those which might be considered as relatively acute, judged from the grouping of symptoms which he gave; others were, it seemed to me, rather those of chronic appendicitis. I think it is, perhaps, hardly fair to call the group of cases, as a whole, illustrative of the operation upon a case during the intermission between recurrent attacks. In reference to the indications for operation, Dr. Richardson has alluded to the discussion at Washington. I remember that subsequent to that meeting, in talking with Dr. Homans, I said to him that my own views in the matter were that operations during the intermissions were desirable in cases where the patient was prevented from earning a living or enjoying life; and Dr. Homans said such was the view he took. It seems to me that another indication, which Dr. Porter has included in his recommendations, and which I think Dr. Cabot's case illustrates in a satisfactory way, is to be found when a person's occupation is such as to expose him to unusual risks in moving about, or in compelling isolation from competent medical advice. In such cases, in the first instance, the advice should be to give up your business and do something else. If the patient is not willing to follow this, the expediency of an operation is his own affair and not that of the surgeon. As for the medical side of this class of cases, it is very desirable to bear in mind that about as many cases get well without surgical treatment as with surgical treatment. It is also to be remembered that if there is a distinct intermission of health between two attacks it is very possible that the past attack may be the last, and the person will have no further trouble. I would also remark that Dr. Porter's statement as to the fre-

quency of recurrence is derived from the paper I wrote four or five years ago, whereas the latest statement made in the recent discussion of the subject at the meeting in Washington, places the number of recurrences at a much higher figure, nearly fifty per cent.

DR. RICHARDSON: I think the only remarks made in favor of the operation were made in Dr. Porter's paper, which I read for him, and by Dr. Homans. I have forgotten what Dr. Homans said but I remember that Dr. Porter's paper came in as almost the only voice in favor of the operation at that time.

DR. PORTER: I had a letter from Dr. Tiffany of Baltimore after that, saying that he urged, especially, that those cases should be presented in full to the Society because he had a case in which he was in the greatest doubt as to what to do, and he had heard nothing except the opposite side, and that was against operation. I only want to say I hope I made it perfectly distinct in my paper that I was not an advocate of operation in every case of recurring appendicitis, but only that there were a certain number of cases the circumstances of which demanded imperatively that the surgeon should be willing to interfere if the patient elected the operation after he had had presented to him the possible dangers. I think we must all admit the fact that there is danger in this operation. The only question is whether it can be reduced to a minimum. In the hands of the best surgeon a simple exploratory incision may sometimes result fatally. It is because we are not absolutely perfect in our technique, but, barring that, it seems to me that this class of cases certainly is going to demand a great deal more of interference in the future than in the past. I was very much encouraged when I came to look up the literature and found as far as I could go that all the cases had recovered.

DR. ELLIOT: I happen to know that there have been one or two deaths in New York.

Dr. Elliot showed the specimen of a case of acute appendicitis. The appendix was gangrenous and perforated, it was about as large as a man's thumb, and had a mesentery thickened to the same size. The omentum was found wrapped about the appendix and had become inflamed and gangrenous, and a large portion of it was therefore removed with the appendix. The operation was done on the third day. The patient recovered.

## Recent Literature.

*A Manual of Obstetrics.* By A. F. A. KING, A.M., M.D. Fourth Edition. Philadelphia: Lea Brothers & Co. 1889.

This manual is among the best of the smaller textbooks on obstetrics. Each successive edition bears evidence of careful revision, and the present edition contains two additional chapters on the intercurrent diseases of pregnancy and the resuscitation of stillborn children. There are also thirty-nine additional illustrations. In an appendix the author gives the report on uniformity in obstetrical nomenclature adopted by the Section on Obstetrics of the Ninth International Congress, held in Washington in 1887, and has largely followed it in the text of the present edition. In his next edition we wish the author would give more extended and specific instruction in the aseptic management of normal cases.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, JANUARY 15, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 253 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DANIEL KELL & UPHAM,  
253 WASHINGTON STREET, BOSTON, MASS.

THE EPIDEMIC OF KOCHISM AND THE NEWS-  
PAPER REPORTER.

THE fact that the new and untried method of Koch produced an immediate and world-wide sensation is perhaps not to be wondered at, but it furnishes nevertheless a very interesting study. What might, for present purposes, be called the epidemic of Kochism first appeared in Berlin at the time of the International Congress, but remained local and dormant for about three months, when it suddenly spread with increasing force and great rapidity, taking roughly the same course as the epidemic of influenza a year ago. It appeared in America, however, before it did in France, perhaps owing to the more positive and far-reaching ubiquity of our press. It has only lately begun to be felt in the far East and South. It is yet too early to say how long it will last, but it shows signs of waning in Germany. A well-marked feature of the epidemic is a sudden revival when the first consignments of "Kochine" reach a given locality. Members of the medical profession are generally attacked a little later than the laity, and often escape altogether, except when brought into the vicinity of newly arrived Kochine. Kochism produces certain typical symptoms in members of the medical profession, who are unfortunate enough to be afflicted with the malady, but our study is limited to the laity, and in fact to one class of sufferers. The effects of the epidemic on the laity differ, and show marked characteristics in different classes, especially among newspaper reporters, members of phibical families, and irregular practitioners, among whom, by careful search, may be found symptoms which are respectively ludicrous, pathetic and disreputable.

A study of the ejections of the first of these classes in the United States alone would furnish material for a volume. Especially in the West, the organization of the medical world of Berlin, and the position of men like Koch in it, are about as well understood as is the office of Her Majesty's Master of the Buckhounds — as may be judged from the following:

According to medical "the" Dr. Koch was a very clever physician, until he discovered how remedy for tuberculosis, and

had he made the formula public, he would have remained so. But because he rightly retains the secret, he is a charlatan and quack. The "code of medical ethics" would make good material for a bonfire.

When the new "K. K. K., Koch's Konsumption Cure" first became prominent, a few papers, either to protect their readers from morbid enthusiasm, or because they felt that Dr. Koch was getting too much free advertising, took a decided stand against the new remedy.

American physicians are inclined to look with disfavor upon the claim of Dr. Koch, of Berlin, that consumption can be prevented by inoculation with the disease. The theory was talked about among physicians on this side of the water years ago, and there were even experiments made by St. Louis investigators, with the result that the idea was abandoned. Koch seems to have been caught in the undertow of the receding theory, and has gathered about him a number of the faddish young doctors who are unwilling to acknowledge that consumption is a constitutional disease and curable only by remedies raising the general tone of the system.

Dr. Koch's alleged consumptive cure is about on a par with the Brown-Sequard humbug, which attracted so much attention a few months ago. It rapidly went out of notice, and Dr. Koch's quackery will soon go the same way.

The interview of local doctors then began, and often resulted about as follows:

Dr. Irwin said: Koch's claim to cure tuberculosis may be O. K. I presume it is. He is a scientist of wide repute and very clever. I haven't seen anything about the methods to be adopted yet, and so I can't tell much about it. If true, it will be a great discovery.

Or, where one very prominent man deigned to speak, it was announced in the graphic style of newspaper headlines:

Schenkelberger on Koch. The Doctor's a Genius and would Scorn False Colors. Tamed the Wild Bacillus, and is consequently no Champ — Dr. Schenkelberger was a Schoolfellow of the Famed Consumption Sluggard, and Knows what he Talks about.

A large number of doctors and apothecaries in the West seem to be relations or school-fellows or passed first assistants of Koch's.

As the press found that the medical profession looked with favor on the new cure, it changed its tone, and began to foretell the coming benefit to humanity in words to this effect:

Consumption is a foe which has blanched the cheek of many a man who would not turn pale in front of the cannon's mouth. Insidious, inexorable, pitilessly winding its slow coils around the citadel of life, it shares in the universal human heart the antipathy felt toward the serpent. It numbers its victims by hundreds of thousands, dragging them impartially from squalid hut and from sumptuous palace. And if it kills many it frightens more. Scarcely a train leaves a great city but bears some panic-stricken fugitive fleeing the dreaded phantom. At one time they hurry to Minnesota, at another to Florida. They hide in caves, they seek the mountain tops, they breathe the healing odor of pine forests, they cross the seas. The fashion changes, but the flight never ceases. . . .

One would think that each town took an interest in the subject, and tried and expected to out-rival its neighbors. They each sent representatives to Berlin. Not only did Chicago announce that it would not be behind New York, but less prominent places expected soon to have some "lymph."

This is now the ruling topic in all quarters of the globe where pills are known and porous plasters place their perforated propriety. It is but meet and proper, therefore, that Peoria, which boasts of an active medical society, should, through her learned and gifted Esculapians, bestir herself in the matter of a reception to what promises to be one of the most beneficent revelations vouchsafed to suffering humanity since Harvey. . . .

At present the whole scientific world, along with the common herd of mortals, is excited over the discovery of a specific for consumption by an eminent German physician, Dr. Koch. This doctor, during an experiment, discovered what he is pleased to term "lymph," a preparation which is said to be worth \$1,300 a drop. An ounce vial of it, injected according to instructions, would be worth the surprising amount of \$780,000. This "lymph" is claimed to be a certain and sure cure for that dreaded of all diseases, consumption.

Everywhere physicians are interested in Dr. Koch's discovery, and some of the most eminent of the world are flocking to Berlin, in order to gain some practical knowledge of the remedy. Nowhere is there more interest manifested in this recent discovery than right here in Bowling Green. Two of our best known and most competent physicians have signified their intention to go to Germany and study the treatment of Dr. Koch.

Some cities are unwilling to be outdone by Koch himself, and we find the names of no less than eleven physicians, whose claims to have discovered the same, or an equally good "lymph," have been considered worthy of publication, not including the host of announcements appearing in connection with advertisements.

#### IMMUNITY AND BLOOD-SERUM.

In an editorial in the JOURNAL April 24, 1890, we briefly reviewed the question of immunity, and concluded that at that time no reasonable theory of immunity could be formulated. The phagocyte theory was shown to be insecurely founded, and was, in fact, even then practically discredited. The evidence regarding the germicidal properties of blood and blood-serum was conflicting, and failed to carry conviction of its supreme importance. The trenchant criticisms of Lubarsch in particular tended towards a conservative view of this explanation of immunity. At the same time the high significance of the work on blood-serum then being pursued by Buchner and others was evident.

During the last year several highly important papers have been published, bearing directly upon the conditions determining the germicidal power of the blood, and these have finally culminated in two remarkable papers by Behring and Kitasato in the *Deutsche Medicinische Wochenschrift*.<sup>1</sup>

Early in the year Buchner published in the *Archiv für Hygiene*<sup>2</sup> a notable and exhaustive research on the bacteria-destroying power of blood. He concluded that the proteid bodies of the serum are to be regarded as the source of the germicidal influence. A few months afterwards Fodor<sup>3</sup> made a still further advance by showing that *alkalization* of the blood increases its germicidal power. These facts in themselves were sufficient to prove the possibilities of this line of work; but they are far surpassed in practical interest by the work of Behring and Nisser, and now by the ex-

ceedingly important results reached by Behring and Kitasato.

Behring and Nisser<sup>4</sup> not only confirmed Bouchard's conclusions that the blood-serum taken from immune animals possesses greater bactericidal power than does normal serum, but also that this bactericidal action is confined to the particular bacterial species used to produce immunity. Thus the blood of an animal made immune against anthrax showed increase of bactericidal power for that particular microbe, but not for other pathogenic bacteria. The same was true of other specific germs. For each particular germ there appeared to be particular immunity-conferring substance. Furthermore, Behring and Kitasato<sup>5</sup> "have succeeded in producing immunity against diphtheria and tetanus, and also in curing animals already infected with these diseases." A summary of their first paper is given in an editorial in the JOURNAL for December 11, 1890.

This result is the more striking in that, till now, no one has ever succeeded in rendering any animal whatever immune against tetanus, although Frnaekel has reached the same position with a different method in regard to diphtheria.<sup>6</sup>

Behring's second article,<sup>7</sup> is equally remarkable. The first paper, written in conjunction with Kitasato, proved that immunity from tetanus, in the animals thus far studied, depend upon the ability of the blood to render innocuous the poison produced by the tetanus bacilli. The second paper is concerned more particularly with diphtheria, and here also the author has arrived at the same striking result. Behring distinctly disclaims any desire to assume that he has discovered a cure for tetanus or diphtheria in man, but no one can be blind to the possible practical significance of his work.

Whether future investigation will confirm Behring's results remains to be seen. The facts emphasized so clearly by Lubarsch are still to be brought into line, and there are many other phenomena of immunity still needing an explanation. Little or nothing is known of the way in which the "bacteria-destroying" and the "poison-neutralizing" properties are related, or indeed if they are related at all. Almost nothing is known of the parts that the leucocytes play in the production of immunity, though there are some facts that seem to indicate that the bacteria-destroying albuminous substances may proceed from the breaking down of the protoplasm of leucocytes.

We seem to be progressing towards the conclusion that there are certain CONTROLLABLE conditions of the blood that render certain pathogenic bacteria powerless to affect the organism. Whether or not this power is due to the presence of "defensive proteids" or "bacteria-killing globulins" or some other factor at present undiscovered, to the practising physician the outcome would be the same. The possibility of curing acute infectious diseases seems to be less doubtful than formerly.

## MEDICAL NOTES.

**PROFESSOR BARTHOLOW'S SUCCESSOR.**—The trustees of Jefferson Medical College have elected Dr. A. P. Brubaker as the successor to Prof. Bartholow in the Chair of Materia Medica and General Therapeutics.

**LEPROSY.**—A few of the more typical cases of leprosy in the Leper Hospital in Havana, Cuba, have been photographed and are now on exhibition at the Marine Hospital Bureau at Washington. These photographs, together with those sent by the consul at Maracaibo, form a complete collection, which health officers may consult at their convenience.

**THE POPULATION OF THE UNITED STATES** ON June 1, 1890, as shown by the *Census Bulletin* of December 12th, exclusive of white persons in Indian Territory, Indians on reservations, and Alaska, was 62,622,259; including these persons the population will probably reach in round numbers 63,000,000.

In 1890 the population was 50,155,783. The absolute increase of the population in the ten years intervening was 12,466,467, and the percentage of increase was 24.86. In 1870 the population was stated as 38,558,371. According to these figures the absolute increase in the decade between 1870 and 1880 was 11,597,412, and the percentage of increase was 30.08.

**IMMUNITY FROM DIPHTHERIA AND TETANUS.**—Dr. Behring has lost no time in making known the chemical agent employed by himself and Dr. Kitasato in their experimental investigations on diphtheria and tetanus. This agent proves to be trichloride of iodine, which, injected subcutaneously in animals inoculated with the viruses, not only cures them, but renders them immune to subsequent infection. Peroxide of hydrogen in ten per cent. solution will also confer such immunity in respect to diphtheria.

**TO REPORT DEATHS FROM KOCH'S TREATMENT.**—The coroner's office of New York city has notified all institutions where Dr. Koch's lymph is being used, that all deaths resulting from such use must be reported at the coroner's office. The order, it was said, was made in the interest and for the protection of the public in the fear that the sensational enthusiasm produced by the reported success of a secret remedy might lead to injudicious and experimental use. General practitioners were also notified.

**VRICHOW'S REMARKS ON KOCH'S FLUID.**—Telegrams in the daily press attribute remarks to Virchow in regard to the effects of Koch's fluid, based upon the results of several autopsies, and that the government has consequently changed its programme in regard to it. These despatches show internal evidence of the desirability of waiting for further particulars, before placing too much reliance upon them.

**DEATHS IN BOSTON AND NEW YORK IN 1890.**—According to the annual statement of the Board of Health, there were 10,181 deaths in Boston the past year, as against 10,259 in 1889. The annual death rate per 1,000 inhabitants (estimating the population as only 120,000) was 21.12. The percentage of deaths

under five years to the total mortality was 32.89. Cholera infantum caused 498 deaths, phthisis pulmonalis 1,495, bronchitis 453, heart disease 783, pneumonia 1,092, violence 450. The total deaths in the city of New York during the year just closed were 40,230, a slight increase over the total of 1889, which was 39,583, as well as that of 1888, which was 40,175. The population being estimated at 1,631,230, the rate of mortality is found to be 24.6 to the thousand, as against 25.1 in 1889, when the population was held to be 1,580,000.

## NEW ENGLAND.

**TYPHOID FEVER AT LOWELL AND LAWRENCE.**—Since last May typhoid fever has been more prevalent in Lowell than in the corresponding period of 1889. This increase was not marked until in October, and was especially noticed in November and December. In these last two months there were four times as many cases reported, and three times as many deaths as in the last two months of 1889. In November, 1890, typhoid fever caused twenty per cent. of the deaths, and in December fifteen per cent.

The cause of this epidemic is as yet unknown. The health department inspector visits each house in which typhoid fever is reported to be present. He records the source of the water-supply, and the name of the milkman. He investigates and causes to be remedied all unsanitary arrangements on the premises, and leaves with the family a circular calling attention to the nature of the disease, and emphasizing the necessity for disinfection of the excreta, according to the directions given.

According to the returns obtained by the inspectors, typhoid fever favored no particular locality, but was prevalent throughout the city.

Houses of proper sanitary construction were visited by the disease, although in less proportion than unhealthy habitations. The patrons of no one milkman seemed especially affected. Nearly all of the citizens are supplied with city water from the Merrimac River, and, of course, the majority of patients used this as their drinking-water. Cases were recorded, however, where the patient had obtained his drinking-water from another source.

No one type of the disease has prevailed. Some cases have been so erratic in their course as to lead to errors of diagnosis. There have been many light cases of short duration, especially in children. In the severe cases intestinal hemorrhage has been a prominent symptom.

Dr. Abbott, of the State Board of Health, is searching for evidences of any unusual pollution of the water-supply, by typhoid dejections, in towns above Lowell on the banks of the Merrimac and its tributaries. Prof. W. T. Sedgwick, of the Institute of Technology, is making a bacteriological examination of the water, to determine the presence of specific microorganisms. Until these gentlemen have finished their investigations, no conclusions can be drawn as to the cause of the epidemic.

Professor Sedgwick has made a preliminary report to the Lowell Water Board to the following effect: "At your request I have undertaken, and am carrying forward, as rapidly as possible, a thorough investigation of the sanitary condition of the water supply of Lowell, with special reference to the possible existence in the city water of the organisms which are believed to produce typhoid fever. I have already collected and examined samples of the water from each ward, from both reservoirs, from the filtering galleries and from the Merrimac River near the in-take and from points above. Up to the present time, however, only negative results have been obtained. Although large numbers of samples have been examined by the approved methods of bacteriology, I have as yet failed to find in them even one typhoid fever germ. The investigation, however, is still incomplete, and it may require some weeks to arrive at positive conclusions. Meanwhile, for reasons which will appear in the full report, it would probably be a wise precaution if the citizens should boil for at least fifteen minutes all water that is to be used for drinking."

The Massachusetts State Board of Health has notified the Mayor of Lawrence to warn the people of that city against drinking the water of the Merrimac river without first boiling it at least fifteen minutes, and not to use the ice cut from the river this year. There are now more than two hundred cases of typhoid and enteric fever in the city, of which the Merrimac is the principal water supply. A recent investigation by the board has led to the above recommendation.

**LEGISLATIVE COMMITTEES.**—Among the joint-standing committees just appointed in the two branches of the Massachusetts Legislature are the following:

**Public Health.**—Senate: Messrs. Gilman, of Middlesex; Reade, of Suffolk. House: Messrs. Stevens, Boston; Boodey, Weyland; Hodges, Nahant; Rudy, Cambridge; Hinckley, Lee; Frazer, Boston; Harriman, Northbridge.

**Public Charitable Institutions.**—Senate: Messrs. Risteen, of Suffolk; Champlin, of Suffolk; Drury, of Middlesex. House: Messrs. Curtis, Marlborough; Thurston, Enfield; Horton, Attleborough; Blanchard, Boston; Sawyer, Danvers; Clarke, Palmer; Bicknell, Weymouth; Savage, Lowell.

**Drainage.**—Senate: Messrs. Donovan, of Suffolk; Clark, of Franklin; Drury, of Middlesex. House: Messrs. Perkins, Somerville; Moore, Waltham; Lawrence, Medford; Hutchinson, Boston; Hinds, Webster; Sparhawk, Marblehead; Lanigan, Boston; Knox, Blandford.

**Water-Supply.**—Senate: Messrs. Bradley, of Essex; Wycf, of Middlesex; Cook, of Worcester. House: Messrs. Johnson, Haverhill; McFetries, Springfield; Finney, Plymouth; Howe, Gardner; Danforth, Lynnfield; Smith, Mansfield; Nutting, Northampton; Burke, Quincy.

#### NEW YORK.

**THE VISITING COMMITTEE'S REPORT.**—The New York County Visiting Committee of the State Charities Aid Association has just made its annual report to the Association. The committee has made a careful investigation of the administration and condition of the various public hospitals and other institutions, and the report contains a record of improvements made during the year, together with suggestions and recommendations. The most important among these

improvements was the extension of the work of the Charity Hospital Training School for Nurses to the Harlem Hospital, which is located at the foot of East 120th Street. There have been built a new dormitory for helpers at Charity Hospital, a new pavilion for women at the almshouse, a new wing at the workhouse, and a bath-house, amusement hall, and work-rooms at the Blackwell's Island Insane Asylum; and there has been a substitution of paid for pauper labor at several of the institutions. The committee urges the desirability of dividing the Department of Charities from the Department of Correction. The disgrace of going to the "Island" it is claimed, degrades the person brought there by misfortune, and the presence of the latter class there lessens the disgrace of those brought there by crime. The report calls attention to the increase in the number of insane in the charge of the city, and points out the necessity for a speedy transfer of the large insane asylums to the care of the State. During the year the admission to the three city asylums exceeded by 258 the total of deaths and discharges. The number of patients under treatment at Bellevue Hospital in the year was 15,161, and the deaths amounted to 1,384.

**MRS. FOGG'S BEQUESTS.**—By the will of Mrs. Fogg, the widow of a rich merchant in the China trade, the New York Hospital receives \$20,000, the Metropolitan Hospital \$10,000, and the Children's Aid Society, \$55,000; and among the many other institutions benefited are the New York Diet Kitchen and the Training School for Nurses of Bellevue Hospital. The largest bequest is to Harvard University, namely, \$200,000 for the erection of an art museum. In addition, Mrs. Fogg bequeathes her late husband's Japanese and East India collection, valued at \$100,000, and the sum of \$20,000, to be applied to the current expenses of the museum and the purchase of works of art.

**CONTAGIOUS DISEASE IN BROOKLYN.**—The report of Health Commissioner Griffin, of Brooklyn, in 1890, shows that there were 5,663 cases of contagious disease reported in Brooklyn during that year, and that of these no less than 2,185 were cases of diphtheria.

**THE collections of Hospital Saturday and Sunday, as thus far reported, amount to over \$28,000.**

#### Miscellaneous.

#### THE EYRAUD-BOMPARD TRIAL.

THIS trial, which took place in Paris during the latter half of last month, attained a wide notoriety largely on account of the discussion on hypnotism which was introduced by the defence. The following<sup>1</sup> is a brief review of the case.

On the 26th July, 1889, mysteriously disappeared a bailiff of Paris called Gouffé. As a coincidence, a

<sup>1</sup> Medical Press, December 21, 1890.

He became the physician to many of the associations for mutual help, seeing large numbers of patients for very small fees, and exercising great ingenuity to perform his duties at the least expense of time and money. His practice finally became very large, but the same habit of seeing and caring for patients expeditiously still remained. He was greatly interested in joint disease, and had his own apparatus for every joint, most of them carrying out the principle of fixation, of which he was an ardent advocate. His offices had a very complete workshop as an adjunct where all his work was done under his own supervision.

He was exceedingly kind to Americans who called upon him, and none left him without being impressed with the originality, honesty and earnestness of the man.

## Correspondence.

### RECORDS FOR CASES OF TUBERCULOSIS TREATED WITH KOCH'S PARATALOID.

Boston, January 12, 1891.

MR. EDITOR:—Inasmuch as the records of observations of cases of tuberculosis treated with Koch's parataloid are being so generally kept, and because a systematic method for general adoption will enable a clearer comparison of results to be made, it seems a good plan to call fresh attention to Gaffky's tables for the observation of the bacilli of tuberculosis in sputum.<sup>1</sup> These tables are employed in the accurate records of the Berlin hospitals, and will be employed in the tabulation of the cases of whose records I have charge in this city. A translation follows:

The cover-glasses should be stained after Ehrlich's (or Zeihl's) method, and should be observed with a Zeiss one-twelfth homogeneous immersion lens and a No. 2 or 3 eyepiece. This being done, the following notation will give at a glance the varying number of bacilli seen upon successive examinations:

- 0 = No bacilli at all.
- 1 = 1-4 bacilli in the entire preparation.
- 2 = An average of one bacillus to every few fields.
- 3 = An average of 1 bacillus in every field.
- 4 = An average of 2-3 bacilli in every field.
- 5 = An average of 4-6 bacilli in every field.
- 6 = An average of 7-12 bacilli in every field.
- 7 = Fairly numerous bacilli in every field.
- 8 = Many bacilli in every field.
- 9 = Very many bacilli in every field.
- 10 = Enormous masses of bacilli in every field.

The latter part of these tables correspond very closely with a similar classification made by the writer in a communication read before the Massachusetts Medical Society in June, 1883.<sup>2</sup>

The importance of securing accurate data, from which to draw our conclusions in regard to the new treatment for tuberculosis, is my reason for troubling you.

Very truly yours, HAROLD C. ERNST, M.D.

### A SECRET REMEDY.

Boston, January 10, 1891.

MR. EDITOR:—Is it not almost time for those who are using Koch's "lymph" so freely to tell the profession what the preparation they employ consists of, if they know it; or, if they do not know what they are using, to cease experimenting on human beings with a preparation unknown to them, and kept a secret by its inventor?

According to the papers, Professor Virchow has made over twenty autopsies of persons "who had died after being treated with 'lymph,'" and declares that while it has not been proven to arrest tubercular disease, it creates new and serious affections of its own.

It may be well, perhaps, to remind the members of the Massachusetts Medical Society of a very wise and beneficial by-law—that the treatment of diseases by preparations, the ingredients of which are kept secret, is held to be irregular and unprofessional.

Our predecessors did better than this. Professor Hayward, who performed the second operation on a patient under ether, refused to perform the operation until Morton had told him what the article was which he was about to administer as an anæsthetic. Yours truly,

CAUTION.

### THE FIRST OPERATION UNDER ETHER.

SOUTH NATICK, January 12, 1891.

MR. EDITOR:—I was present at the first operation upon one under the influence of ether. I can testify as to the strict truth of Dr. Dwight's three statements. There is some reason for doubting the justice and accuracy of his criticism of the rest of Dr. Jewett's assertions. For I distinctly remember that Dr. Warren, in commenting upon the case, said he noticed the blood during the operation was very dark, and that he thought the anæsthesia might be owing to the blood being carbonized, thus producing a condition similar to that induced by inhaling coal-gas. These remarks were received with a burst of applause.

It is to be remembered that we were ignorant as to the nature of the anæsthetic, any farther than it manifested itself by its physical properties, the general remark being made by those around me, that "it smells wonderfully like sulphuric ether." Very truly yours,

GEO. J. TOWNSEND, M.D.

### RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JANUARY 3, 1891.

Cities.	Estimated population for 1890.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

diarrheal diseases, whooping-cough, erysipelas (and fevers) 388, acute lung diseases 532, consumption 556, diphtheria and croup 175, typhoid fever 537, scarlet fever 51, diarrheal diseases 35, measles 34, whooping-cough 31, cerebro-spinal meningitis 11, erysipelas 9, malarial fever 5.

From diarrheal diseases New York 10, Philadelphia 3, St. Louis and Charleston 4 each, Chicago and Brooklyn 3 each, Boston, Washington, Worcester, Fitchburg and Gloucester 1 each. From measles New York 22, Chicago 3, Brooklyn and Boston 2 each, Washington, Charleston and Lawrence 1 each. From whooping-cough New York 9, Brooklyn 8, Chicago 7, Philadelphia 3, Washington 2. From cerebro-spinal meningitis Chicago and Washington 3 each, Brooklyn 2, New York, Boston and Cincinnati 1 each. From erysipelas New York, Chicago and Brooklyn 2 each, Washington, Worcester and Lawrence 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,559, for the week ending December 20th, the death-rate was 25.1. Deaths reported 4,881; acute diseases of the respiratory organs (London) 753, measles 246, whooping-cough 107, scarlet fever 51, diphtheria 51, fever 47, diarrhoea 29.

The death-rates ranged from 15.2 in Leicester to 51.6 in Preston, Birmingham 21.8, Bradford 18.6, Hull 16.1, Leeds 22.9, Liverpool 26.9, London 26.9, Manchester 31.9, Nottingham 20.0, Portsmouth 20.4, Sheffield 25.2, Sunderland 19.9.

In Edinburgh 24.4, Glasgow 24.5, Dublin 28.2. In the twenty-eight greater towns of England and Wales with an estimated population of 9,715,559, for the week ending December 27th, the death-rate was 27.8. Deaths reported 5,186; acute diseases of the respiratory organs (London) 806, measles 199, whooping-cough 190, diphtheria 55, scarlet fever 51, fever 39, diarrhoea 38.

The death-rates ranged from 15.2 in Brighton to 41.6 in Preston, Birmingham 25.7, Bradford 21.7, Leeds 28.8, Leicester 27.7, Liverpool 31.9, London 26.3, Manchester 43.6, Newcastle-on-Tyne 21.3, Salford 30.3, Sheffield 29.6, Sunderland 32.9.

In Edinburgh 20.2, Glasgow 20.2, Dublin 21.3.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 3, 1891, TO JANUARY 9, 1891.

By direction of the Secretary of War, the following-named medical officers were promoted, without delay, to Fine Ridge Agency, South Dakota, and report in person to the commanding general, Department of the Platte, for duty in the field: Captain Henry S. Kirtland, a assistant surgeon, Captain LOWIS F. Kirtland, a assistant surgeon, Captain EDWARD E. Kirtland, a assistant surgeon, S. O. L. Par. 2, A. G. O., December 30, 1890.

By direction of the Secretary of War, Brigadier General CHARLES SEIDENBERG, surgeon general, will accompany the troops, report to the city, and assume the duties of his office, S. O. L. Par. 9, A. G. O., Washington, D. C., January 3, 1891.

By direction of the Secretary of War, the assignment of Major JAMES P. KENNEDY, to duty at Fort Supply, Indian Territory, in Special Orders No. 135, September 4, 1890, Department of the Missouri, S. O. L. Par. 6, A. G. O., January 6, 1891.

ALLEGATIONS.

Colonel CHARLES SEIDENBERG, surgeon general, to his surgeon general,

eral, with the rank of brigadier general, December 23, 1890, vice Baxter, deceased.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 10, 1891.

M. L. RUTH, surgeon, ordered to the U. S. S. "Newark," February 2, 1891.

W. H. RUSH, passed assistant surgeon, detached from U. S. S. "Saragota," and to the U. S. S. "Newark," February 2, 1891.

RICHARD ASHERIDGE, passed assistant surgeon, ordered to the U. S. S. "Saragota."

#### SOCIETY NOTICES.

AN AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. — A convention of American physicians interested in electro-therapeutics has been called to meet at the Academy of Medicine, No. 17 West 43d Street, New York, on January 22, 1891, at 11 A. M., for the purpose of organizing an American Electro-Therapeutic Association. Those interested are cordially invited to attend, and are requested to inform Dr. Massey, 212 South 15th Street, Philadelphia, of their acceptance of the invitation.

G. BETTON MASSEY,  
AUGUSTIN H. GOELET,  
HORATIO R. BIGELOW.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. — The Section for Clinical Medicine, Pathology and Hygiene will meet at 19 Boylston Place, on Wednesday, January 21st, at 7.45 o'clock.

Dr. G. Liebmann will exhibit and describe a new appliance. Dr. H. J. Barnes will read a paper upon "Sewage. Application to Land the Best Method of Treatment." Prof. W. T. Sedgwick; Prof. T. M. Brown, of the Massachusetts Institute of Technology; Prof. E. S. Wood, of Harvard University; Drs. H. P. Walcott and S. W. Abbott, of the Massachusetts Board of Health; Drs. S. B. Jorgin and T. H. McCollom, of the Boston Board of Health; Col. Geo. E. Waring, of Newport, R. I.; Drs. C. F. Folsom, G. F. Tarbell and J. A. Jeffries, of Boston; Desmond Fitzgerald, Esq., and Mr. Wm. Jackson, of the Water Department, have been invited to take part in the discussion.

ALBERT N. BLODGETT, M.D., Sec'y., 138 Boylston St.  
E. G. CUTLER, M.D., Chairman.

#### DEATHS.

Coert Dubois, M.D., of New York, died, January 1st, aged forty-two.

Dr. Gleason B. Perry, one of the oldest practitioners in Brooklyn, N. Y., died, December 30th, aged sixty-four.

Dr. Marinus W. C. Gori, lecturer on military sanitary science in the University of Amsterdam, died on December 27th.

#### BOOKS AND PAMPHLETS RECEIVED.

All around the Year. Boston: Lee & Shepard. 1890.

Architecture and Sanitation. By Wm. Paul Gerhard, C. E. Reprint. 1890.

## Lecture.

KOCH'S TREATMENT OF TUBERCULOSIS.<sup>1</sup>

BY HAROLD C. ERNST, A.M., M.D.,

*Physician to Out-Patients, Massachusetts General Hospital; Instructor in Bacteriology, Harvard Medical School, etc.*

GENTLEMEN:—By the kindness of the Medical Faculty, I have been requested to address you to-night upon a subject which is occupying the minds of all of your elder brethren in the medical profession at the present time, and to give you, as clearly as possible, some idea of what this seems to us to be, together with a few of the reasons for my personal belief in the efficacy of this new treatment against tuberculosis, as was apparently shown to me by the effects I saw while at Berlin.

What I have to say to you will be practically a repetition of an address I made Thursday evening in the amphitheatre of the Massachusetts General Hospital before the medical profession.<sup>2</sup>

I have had the honor of sharing in the introduction of this treatment in Boston; and the first patient upon whom it was tried in this city, is still under my care at the Massachusetts General Hospital in Dr. Tarbell's service and by reason of his courtesy. The number under treatment is for the present limited, because when we look at the matter soberly, we must all acknowledge that it is a great clinical experiment, and the impressiveness of the stage through which we are passing is one which will grow greater as time goes by. We, as medical practitioners, are doing a thing which has never before been known in the history of medicine. We are, at the suggestion of one man, employing a material of whose composition we are still ignorant. And we are doing this in perfect faith, and feeling we are justified in our course, because this material, and the suggestion of its employment, comes from one of the greatest medical minds the world has ever produced. This one fact of the general acceptance of Koch's paratuberculin, and its employment against tuberculosis by the medical profession, says more than any one individual can find words to express, of the greatness of character of this man, who has been, to my mind, for a number of years, one of the most impressive characters that has ever crossed the medical stage. He is the one man in scientific medicine who thus far has never made a mistake. Going back some twenty years ago to the time of the Franco-Prussian war, through which he served as an assistant-surgeon, passing from that period to a struggle for a practice in an obscure north German town, without money, influence, or friends, he stands to-day at the pinnacle of the medical profession; and we all look to him for further developments in the line of his pre-

vious researches. He is practically the one man by whom the possibility of research in bacteriology has been laid open to us by the development of methods which enable the average man to carry out something in the line of work in which he himself is engaged. This does not enter a claim for his absolute precedence in bacteriology, for there were others before him, Pasteur, of course, among them; but it is owing to the introduction of his methods that we have reached our present point.

This is one side of the question which should be impressed upon you. You are now passing through something similar to the experiences of forty-five years ago, when the first suggestion for the use of ether was made. I have been told of the excitement at that time by men who were then about your age, and it can only be compared to the excitement that is now going on in Berlin, and to a lesser extent in the other medical centres throughout the world. We are trying this material in the line of a great clinical experiment, to prove or disprove its efficacy.

The first thing to discuss before such an audience as you make up, is to indicate as clearly as I can, what this material is; and before I can definitely give you my idea of what it is, I must tell you what it is not. Probably what it is not, is the thing which has been impressed upon you that it is. In the first place this material is distinctly not a vaccine. It bears not the slightest resemblance to one, and it is very easy to see why, if you recall what a vaccine really is. A vaccine requires for its effect and action something in the nature of vitality—an organism. There must be something present capable of reproduction. It must have some vitality, and the best example is the "vaccine virus," which we see employed daily as a preventive against small-pox. A vaccine has distinctly the power of self-reproduction, if a minute amount is introduced into an abraded part, and a local reaction of a very marked degree is set up; this does not occur in our experiments with paratuberculin, therefore this material is distinctly not a vaccine. Again, it is distinctly not an attenuated virus. All the French methods, so far as completed research has been obtained, have been in the line of attenuated virus, which simply means that the specific agent in the prevention of any infectious disease is deprived of a portion of its virulence by being subjected to artificial cultivation, by increasing, perhaps, the temperature in which it develops by a change in the atmospheric pressure, or a change in the oxygen; thus something is altered, and the virus, as, for example, the anthrax bacillus, loses its power to produce the full and violent form of the disease. In some such way this organism, the bacillus of anthrax, which, under ordinary conditions and in full possession of its virulence will produce death within twenty-four hours in the lower animals, may be so changed in its power of producing the disease, yet retaining its power of growth, as, when introduced in large quantities into an animal's economy, to effect only a partial or no disturbance. This is an illustration of an attenuated virus. Another example is furnished by the method of treating the spinal cords of animals, particularly rabbits, dead of rabies. The cords of such animals contain the virus in its full intensity, and when subjected to certain conditions of drying it gradually loses its power to reproduce the disease, until at the end of two weeks it has no such power whatever. During these two weeks the strength

<sup>1</sup> Lecture delivered at the Harvard Medical School, Saturday, January 10, 1891.

<sup>2</sup> At the address to the members of the medical profession given by Dr. Ernst, at the invitation of the Staff of the Massachusetts General Hospital, in the operating theatre of that hospital, Dr. C. B. Porter made the following introductory remarks:

Gentlemen, Members of the Medical Profession:—"A member of the staff of this hospital, by laborious work in the laboratory of Professor Koch, of Berlin, by painstaking research in his own laboratory at the Harvard Medical School, has made himself an authority in bacteriology. Recently he has had exceptional opportunities, both by personal interviews with Professor Koch himself, and personal observation at the bedside in various Berlin clinics for acquiring a knowledge of the action of 'Paratuberculin,' which is the name given to the fluid by Professor Koch, which he claims is of service in the treatment of tuberculosis. It seemed to the hospital staff eminently desirable that the profession should have an opportunity to hear from him the result of his experience, and it is by their invitation that you are here to-night, and that I have the pleasure of presenting to you, Dr. Harold C. Ernst."

of the virus is gradually *attenuated*. We must, therefore, exclude any consideration of Koch's material as an attenuated virus, for absolutely none of the results which follow the injection of this material either into man or the lower animals are followed by anything which we can in the least ascribe to the action of an attenuated virus.

Therefore, having shown that Koch's material is neither an attenuated virus nor vaccine, what else can it be? We now come to the knowledge gained in years past in bacteriological research, a consideration of which enables us to give, without much hesitation, what seems to me a fair explanation of what this material is, and in order that you may clearly understand what I refer to, a few words in regard to the behavior of bacteria under cultivation is necessary. As most of you have seen, or will see, before you leave the school, the method of developing bacteria is, commonly speaking, by the employment of test-tubes filled for about one-third of their length with nutrient gelatine, or some material more or less favorable for the development of the bacteria under observation. This nutrient gelatine is somewhat of an amber color, and the method of planting the bacteria in the tube is by means of a platinum wire which has been sunk into a glass rod at one end and is free at the other. The free end is dipped into material containing the organism, and then immediately plunged directly through the centre of the nutrient material. The result of such a procedure is a visible line through the centre of the gelatine. If this is kept under observation for a short time, depending upon the time necessary for the development of the colony of bacteria, there is observed a gradual thickening of this line on both sides, and occasionally an elevation above the gelatine, then the further spreading of this colony of bacteria ceases, and does not go on any more at any time. For a long time it was difficult to explain why that occurred, but the knowledge which has come to us of late years furnishes a perfect explanation of why the colony does not grow farther out, and why its vitality is not destroyed. The bacteria take from the nutrient gelatine certain elements necessary for their development. They leave, therefore, the nutrient gelatine in a state of partial chemical decomposition, and these unstable chemical elements come together and form new chemical compounds, all of which occurs directly along the outlines of this colony. Among these new chemical compounds have been found, during the last few years, an entirely new series of alkaloids of such unstable chemical nature that we are unable, in many cases, to separate them, to analyze them, or to secure their chemical symbols. The great element in this difficulty lies in the fact that most of the alkaloids are destroyed by a low degree of heat, and as we know, chemistry depends largely upon an extreme degree of heat for many of its analyses. Some of the alkaloids are not destroyed by such low degrees of temperature, however. A great characteristic is that they are inhibitory to the development of bacteria, and a rich variety of bacterium produces in a given nutrient material a special alkaloid or ptomaine, which is inhibitory to its further growth, but does not destroy it vitally. This, it seems to me, furnishes a very perfect explanation of what Koch's material may be in the exploration of what goes on within the body, after it is used in a correct. And the same idea is applicable not only in the disease tuber-

culosis, but there have already been announced researches suggesting the possibility of arresting the progress of other diseases in the same way. This is said to have been obtained in anthrax, and there is a strong hope of similar results in diphtheria, tetanus, and scarlet fever.

This material, it seems to me, can be nothing else than the ptomaines produced by the development of the bacteria of tuberculosis in some medium which permits of this alkaloid being separated out of the nutrient material after the bacteria of tuberculosis have produced it. I do not see how it can be anything else, unless it be the ptomaine produced by some other form of bacterium, which has been found by Koch to act better in respect to the arrest of the development of that organism. Therefore, as far as our knowledge goes now, this is what this material seems to be. It is probably the ptomaine produced by the development of the bacilli of tuberculosis. Precisely in what nutrient material the bacillus is grown, or what is the precise method of its removal, it is, of course, impossible to say. There are certain things which could be said, which might furnish a *probability* as regards the methods of its production, but even if correct, no such announcement should at present be made.

As corollaries to what I have said, it follows most emphatically that this treatment is *not an inoculation*. An inoculation requires the introduction of something vital which will produce its kind, — will reproduce itself, in other words, — and this is distinctly what Koch's material does not do. The treatment is accomplished by a simple subcutaneous injection, not by an inoculation. It equally follows that Koch's material has absolutely nothing in common with a *lymph*. It is not a lymph; and if any of you will take the pains to look up the meaning of lymph in your medical dictionary, you will see how strongly the fact will be impressed on your minds that this material does not accord with the definition there given of lymph. The proper term has been suggested by Koch, himself, *paratuboid*. I do not know the derivation of the word, but it seems to be distinctly derived by analogy from these new alkaloids, these ptomaines.

When I say that these ptomaines are the product of bacteriological development, do not picture to your minds that they are in any way the *excreta*. They are not excreta. They are simply the products coming from the nutrient material, because the bacteria have absorbed some of the elements of the original material.

I have given you as far as I am able some sort of an idea of what this material probably is. Then comes the question as to what it probably does. To judge by the newspaper reports these effects are actually marvellous. I have seen one newspaper account of a man in the last stages of pulmonary tuberculosis who recovered under the doctor's eyes. It is hardly necessary to say that that sort of thing is not true. As far as my observation goes, extending over a superficial examination of some two hundred and fifty to three hundred cases, and the thorough examination of about thirty, and the treatment of something like twenty-six, the effects are double. In the first place they are local. By local I do not mean at the seat of the subcutaneous injection, but local effects at the seat of the pathological process; and there are general or systemic symptoms. The general symptoms consist, on the average, of a very marked rise of temperature. Most of these general symptoms occur, on the average, in

from eight to twelve hours after the injection of the usual dose of this material. There may be a marked and sharp rise of temperature running up as high as  $104^{\circ}$ – $105^{\circ}$  F. There is a very great increase in the rapidity of the pulse and respiration. I have seen the pulse as high as 160 per minute without dangerous symptoms following. There is great headache, chills, and shivering lasting for some time, pains in the bones; and sometimes a very marked jaundice, not uncommon in surgical cases, but rather rare so far as I have observed in cases of pulmonary tuberculosis. These general symptoms last, on the average, about twelve hours after their appearance, when they all gradually subside, and the patient returns to his condition before the injection. There may be very marked depression in temperature sometimes instead of a rise in temperature. One of the cases under my charge, showed this. On last Tuesday, two hours after the treatment, the temperature fell  $2\frac{1}{2}^{\circ}$ , reached  $95\frac{1}{2}^{\circ}$  F. There was not the slightest other indication of anything going wrong with the patient.

There is in some cases, particularly in children, a very obstinate diarrhoea, nausea, vomiting, and occasionally collapse. But so far as my observation goes, the collapse is never great except in cases where the general powers were very much diminished before the treatment began. Nephritic disturbances have also been observed. Albuminuria and symptoms of acute nephritis, which subsided without apparently producing any permanent results. It must of course be remembered that the first case was only treated in October last, but so far as it has been possible to say, nephritic disturbances have disappeared. It is also a question whether these kidney disturbances were brought on by this material. Marked erythema is not uncommon and occurs, in distinction from icterus, in pulmonary cases, — as a rule the icterus in the surgical, and the erythema in pulmonary cases. I doubt, however, if this is anything like a hard and fast distinction.

In regard to the local changes which are observed, they are most prominent where the pathological change is visible to the naked eye. This necessarily, as you must know, is most prominent and most easily observed in cases of lupus, a virulent skin disease or skin tuberculosis, and the changes there observed are very marked, indeed. In this case also, the changes are limited to the locality of the pathological lesion; and, in lupus, these changes consist of a marked increase in hyperemia of the part with an increase in the infiltration of the tissues. Crusts form upon the ulcerating surfaces, which become thicker and thicker after each treatment, and finally fall off, leaving apparently healthy granulating tissue beneath. At the edges where there is no ulceration, the characteristic appearance is the formation of thick, heavy, dry, whitish scales, which gradually fall off as treatment goes on. This marked increase of activity is accompanied usually by a great amount of pain in the affected part, which comes on and lasts the same time as the general symptoms; so that the average patient is in about the same condition twenty-four hours after the injection that he was before it. These reactions, however, are not limited actually to twenty-four hours. There are what are called "delayed reactions," and these occur sometimes as late as forty-eight hours after treatment with a small dose. So, too, the subsidence of the symptoms is by no means constant. In a case

which I have under treatment, injection was made on Saturday morning. Until one o'clock Monday morning there was practically no change from the normal; then the temperature was  $103\frac{1}{2}^{\circ}$  F.; then there was a gradual fall; and on Tuesday another rise to  $102\frac{1}{2}^{\circ}$  F.; again a gradual fall; and on Wednesday still another rise to  $101\frac{1}{2}^{\circ}$  F.; and only on Thursday did the temperature finally return to normal, thus giving a delayed reaction and a gradual subsidence.

(To be continued.)

### CEREBRAL TUMORS WITH CLINICAL CASES.<sup>1</sup>

BY JOSEPH STEDMAN, M.D., JAMAICA PLAIN.

UNDER the head of intra-cranial tumors are included growths and parasites occurring in the skull, and aneurisms of the cerebral arteries.

The general symptoms of tumors of the brain, vary almost indefinitely, for they may be simply those of reflex or direct disturbance of the stomach and other viscera, when hydatids or fibrous growths are their producing cause, or they may be the special feature of carcinoma, tubercle or syphilis, when any one of those dyscrasias is the primary factor in the formation of the adventitious product.

Neimeyer says: "The pathogeny and etiology of cerebral tumors is very obscure. This is true, not only of carcinoma, sarcoma, glioma and myxoma, but also of the rarer tumors, cholesteatoma or pearl tumors, lipoma and cystoid growths."

The influences which give rise to tumors in other localities are those also upon which tumors of the brain depend.

In consequence of hereditary predisposition, an abnormal hyperplasia takes place in the connective and epithelial tissues of the blood-vessels and their sheaths. In this hyperproduction the original character of the affected tissue may be retained, or it may become more or less altered by modification of the newly-formed elements and by changes in their relations to the connective tissue and vascular distribution.

Cerebral tumors occur more frequently in men than in women, the proportion having been estimated as ten to six. Of all cerebral tumors the tubercular is the most frequent, and is usually accompanied by tuberculosis of other organs. It is rare for it to occur primarily in the brain, and in this respect it differs from cerebral cancer, which is more apt to be of primary origin.

Brain tumors in their pathological history are divided into groups. In the first we have glioma, which is formed by proliferation of the neuroglia.

Obernier says: "In respect of color and consistence, the tumors are often difficult to distinguish from the normal brain matter. They are for the most part, whitish, or when the vascular development is abundant, they are reddish, and may be divided into hard and soft gliomata. . . . The composition of the former approaches that of the fibromata, but yet it is only in the most highly developed forms that an intercellular substance with parallel fibrillae is attained to. The cells are scanty and usually have several nuclei.

"The soft gliomata contain more cells, which pre-

<sup>1</sup> Read before the Boston Society for Medical Observation, November 3, 1890.

sent various appearances, but are commonly small and deficient in plasma. In the often very friable matrix, networks of fibrillar are present, in the points of intersection of which, cells and nuclei are imbedded.

"An abundant vascular development leads to hæmorrhages, which are difficult to distinguish from simple apoplexies. In addition to the minute examination of the margins of the apoplexy, we may be aided in such cases by the fact that glioma usually occurs in the white substance of the hemisphere where apoplexies are rarely seen."

We have also, of the same structural type, hyperplasia of the pineal gland.

The following tumors, from their rarity and the slight disturbances which they produce, are more of anatomical than clinical interest:

Psamomma, or sand-tumors; melanoma; neuroma; hyperplasia of the anterior half of the pituitary gland; cysts; and cholesteatomata, which are the connecting link between the above neoplasms and those in the following group:

Tubercular tumors, carcinoma, sarcoma, myxoma, lipoma, osteoma, angioma, inter-cranial aneurisms.

Various disturbances occur as the result of inter-cranial tumors; except in some instances they are not referred to the brain. There are disturbances of the psychical functions; of the nerves of sense; of motion; vertigo and headache, sometimes vomiting; occasionally of the circulation when the position or rapid growth of the tumor, or complications, produce an effect on the pneumogastric. Fever is not the rule in the ordinary course of cerebral tumors.

The diagnosis of inter-cranial tumors may be difficult, and at times impossible. Then, again, the symptoms may be so pronounced as to make the diagnosis sure, and to allow of relief by surgical means.

The treatment must be adapted to the individual case, and such means used as will tend to promote the comfort of the patient and relieve the urgent symptoms.

In cases where an injury has been received, either recent or remote, the late advances in cranial and inter-cranial surgery afford means of relief, which, a few years since, would have been doomed to a hopeless prognosis.

The prognosis is generally unfavorable, the time longer or shorter according to the form of tumor. Even with the diagnosis tolerably sure the prognosis as to time *must* be in doubt, the final result nearly always fatal, except where surgery can aid in the removal of the diseased condition.

The following cases illustrate some of the forms of cerebral tumors, with the pathological appearances found by post mortem examination.

CASE I. E. W., aged twenty-three years, eleven months. I saw him professionally December 1, 1888. He complained of a pain located near the frontal eminence of the frontal bone, about two inches above the supra-orbital arch. This pain did not occupy a space more than an inch in diameter, and was moderately severe, but did not in the least affect his appetite, which was good as usual. It commenced the day before, he having been, apparently, in the best of health to that time. The pulse was 60; the temperature normal. Bowels had been sluggish for a day or two. He was perfectly free from pain in every other part of the body. From the pulse and tongue I concluded he was going to have jaundice. I directed a cathartic and a restricted diet, with *rest*.

December 2d. Pulse, 60; temperature, normal; condition unchanged after the action of the cathartic. Pain quite as severe, but not sufficient to prevent sleep. Gave bromide of sodium in ten-grain doses once in two hours, and until the head was relieved, and continued rest and careful diet.

December 3d. Pulse, 60; temperature, normal; pain not so marked. Had a good night.

December 4th. Pulse, 56; temperature, normal; severe pain at the same spot; no tenderness of cervical vertebra; no trouble with vision. Gave another hepatic pill, as there was a jaundiced hue over a large portion of the body and the diagnosis *seemed* to be jaundice. Continued bromide.

December 5th. Pulse, 50; temperature normal. Was much more comfortable; pain nearly absent; sat up some, and went out for a short walk. Good appetite, and a better diet allowed.

December 6th. Did not see him. He went out with his camera, feeling so comfortable that he went a mile from home, and made several negatives, returning home in good condition.

December 7th. Comfortable; pulse, 56; temperature normal.

December 8th. Did not see him.

December 9th. Pain returned during the night; pulse, 40; temperature normal. Seemed for the first time to be sick generally. Loss of appetite. A careful examination gave no evidence of cerebral trouble, except the pulse-rate being so low made me for the first time suspicious that something more than jaundice was causing his sickness.

December 10th. Pulse, 50; temperature normal; appetite fair. Morphia  $\frac{j}{\text{r. n.}}$ . Procured a trained nurse to-day.

December 11th. Pulse, 50; temperature normal, remained about the same.

December 12th. Pulse, 54. Temperature normal. Commenced to suffer pain again in the same localized place. Gave a hyperdermic of one-quarter grain morphia. Saw him at 8 p. m., and found him quite comfortable. After midnight he was quite restless, but not in much pain as one dose of one-sixth grain relieved him.

December 13th. On my morning visit I saw immediately on entering the room that a great change had come over him. He was partially unconscious, with hemiplegia of the left side—loss of sensation and partial aphasia. It was evident that some serious lesion had occurred in the right hemisphere of the brain.

Called Dr. S. G. Webber in consultation. After a careful survey of the history of the case, with ophthalmoscopic examination, the latter being negative, we were agreed that there was a tumor of the brain, with rupture of some vessel in the neighborhood of the tumor; and we concluded that the tumor was situated in that part of the brain where the localized pain had been the prominent symptom. The kind of tumor could not be determined from the history of the case.

It was evident at this time that death would result in a day or two. Pulse to-day, 72; temperature, 100°, for the first time above normal.

December 14th. He went on much the same, taking some liquid food. Pulse, 96; temperature, 100°; evening temperature, 102°. Was more and more confused mentally, and said "yes" when he meant "no" and "no" for "yes." The night was fairly comfort-

able, and coma came on at midnight; and he died early on the morning of the 15th, making the time from the first pain in the head to the close, fifteen days.

December 16th. Autopsy, thirty hours after death, by Dr. R. H. Fitz. On inspection of the base of the brain, the right frontal lobe was evidently considerably larger than the left and crossed the median line. On palpation this portion was exceedingly soft, and indicating the presence of a semi-fluid or semi-solid mass of the size of a small peach.

On section, a mass of dark-red clotted blood intermingled with white portions lay in the right corpus striatum, where it was adherent over a space as large as the finger nail. The mass was as large as an English walnut and filled a cavity in part formed at the expense of the white substance. The clot fell away from the wall of the cavity, which was stained of a reddish-brown color, as was the continuous brain substance for a certain distance.

The left ventricle was distended with a bloody fluid and was somewhat dilated. The right ventricle contained a somewhat similar fluid and was not dilated.

The pia mater of the convexities was injected, and the gray matter of certain convolutions in the right parietal region was swollen and spotted with numerous red points. The examination of the other organs was negative, with the exception of adhesions from a former peri-splenitis and peri-hepatitis. (This came from a severe typhoid fever which he had several years before.)

The microscopical examination of the clotted mass showed that it was composed of blood and a tissue. The latter was composed of numerous large round cells, considerably larger than the cells of normal neuroglia. They were separated from each other by scanty homogeneous intercellular substances or by fibrillae. Occasionally clusters of spider cells were seen. These abnormal cells were evidently a new formation, and were indicative of a brain tumor, or glioma or glio-sarcoma, evidently the source of the fatal hæmorrhage. The punctate hæmorrhages of the surface being probably the result of obstruction to the flow through the corresponding arachnoidal veins.

CASE II. In December, 1887, Miss B. consulted me for debility, with anæmia. She had no other trouble that could be ascertained. Treatment for two or three months gave good results, and her health appeared completely restored.

The latter part of December, 1888, she went to New Britain, Conn., for a visit, and in a day or two was taken suddenly ill. Dr. H. C. Deane was called to see her. The history of her sickness and the autopsy is as follows, taken from a letter written to her sister by Dr. Deane after her death.

When she went to Connecticut her sister says she appeared to be in fine health and spirits.

I saw the patient on Sunday at 5 p. m. and found severe headache, more on left side of head; some mental dulness; no chill; no rigors. Temperature normal; pulse normal. Tongue furred with slight yellow coating; pupils slightly and equally dilated. She gave rationally the history of a previous attack of rheumatism, also of anæmia; said she had recovered from both. She had no numbness in any part of the body, and no loss of motion in any muscle. There had been obstinate constipation for two weeks; and her breath and the odor from the body was that of bile.

I gave her laxative powders and a small dose of anti-febrin for the neuralgic pain.

Monday, 6th. No movement of the bowels; stupor increased; urine scanty. Temperature normal; pulse, 60. Headache greater, and over the whole head. All other symptoms the same as yesterday. Examined heart and found a slight murmur, but do not think it denoted anything of value; no enlargement of heart, and no sign of nervous irregularity. Gave a stimulant and a diuretic and a laxative followed by an enema; but no movement of the bowels. Urine came freely after a few doses of the diuretic.

Tuesday, 7th. No movement of the bowels. Pulse, 72; temperature normal; stupor greater; urine free; pupils same; no new symptoms; headache less. She was roused to answer questions with difficulty. Cathartic treatment and enema with no result; no distention of abdomen. Itching over the whole body. She was inclined to move hands and feet uneasily most of the time.

Wednesday, 8th. Dr. E. P. Swasey in consultation. Pulse, 72; temperature normal; pupils same; urine passed involuntarily; sensation and motion in all parts of the body; mental recognition lost.

At 7 p. m. there had been no movement of the bowels. Pulse, 92; temperature, 100°; consciousness entirely lost; pupils normal. Several convulsions followed in succession, involving both sides of body equally.

Thursday morning. Found the patient in a dying condition. Pulse, 130; pupils contracted equally; tonic contraction of muscles on both sides of body, involving both flexors and extensors. Dr. Swasey, in consultation, could suggest nothing more to be done. There had been three attacks of vomiting (one each day), of greenish offensive bile. There was slight jaundice.

*Autopsy.*—Kidneys normal. Liver slightly congested. Gall-bladder distended. In the intestines was considerable decomposed bile. Stomach normal. There was a slight thickening of the mitral valve of the heart, which otherwise was normal in size and well-nourished. Lungs normal.

The brain was normal over the cortex of the cerebrum; ventricles normal. At the base of the brain, occupying the situation of the left optic thalamus and the left corpus striatum, was a mass of broken-down brain substance, soft and showing complete destruction of those parts of the brain; in the centre was a clot from recent hæmorrhage. The left cerebellum was externally congested, and showed some capillary bleeding.

My belief is that the vegetation on the valve of the heart allowed a particle to ascend to the locality of the brain trouble, forming a thrombus. This degenerated until it allowed of the hæmorrhage, which probably occurred at the time of the sudden change in pulse and temperature followed by the convulsions. The destruction of this most important part of the brain had gone on without showing any paralysis, or change in pulse or temperature or difference in the pupils.

The utter failure to relieve the bowels was due to paralysis of this organ, the only paralysis present, but which was unknown until the autopsy.

CASE III. Mr. H. D. M., aged sixty years. I was called about 4 a. m. December 31, 1887, to see this patient. Found he had been suffering about an

hour with vomiting and diarrhoea and distress in the head; vomiting bilious in character. Did not seem very ill, but quite restless. Spent an hour with him, and he became much more comfortable. Saw him at 9 A. M., and found him with headache. Vomiting and diarrhoea had ceased. Early in the evening found him with paralysis of left side; consciousness still present, but indifferent, and conversation somewhat indistinct, but knew those about him.

Dr. Webber in consultation. Our diagnosis was brain tumor in region of base of brain, and concurred in by Dr. Channing who also saw him then and in the forenoon of same day.

January 1, 1888. Patient continued much the same; paralysis slowly increasing; urine sufficient. Pain in the head relieved when under small doses of morphia.

January 2d. Patient had failed much during the night. Lungs acting badly from extension of the paralysis. The symptoms clearly indicated the base of the brain as the seat of trouble. He died quietly and rather suddenly at noon. Sickness, fifty-seven hours in all.

He was apparently well Friday, the 30th of December, and went to business in the city. Several years before I attended him with a mild typhoid which had a slightly elevated temperature and pulse, the latter a portion of the time, sub-normal, one-half to one degree. He had at this time peculiar pains in the head, which led me to call in Drs. Webber and Channing. At that time we felt there was some danger of a brain tumor. He made a good recovery in due time, although he was ill about three months. This was in 1882—October, November and December.

After this sickness he saw me a few times, at intervals of some months, for indigestion; and occasionally he would complain of pain in the head, though not localized. He was able from January, 1883 to December 31, 1887, to attend to the details of an exacting and anxious business.

*Autopsy*, January 3, 1888, at 4.30 P. M. by Dr. W. W. Gannett.

Head alone opened.

Body large, well developed, well nourished. Calvaria thick. The right frontal sinus extended nearly to coronal suture.

Dura not remarkable. There was a slight amount of clear fluid in the meshes of the pia. The brain did not wholly fill the cavity of the skull; it weighed 1,422 grammes. The blood-vessels in the base and in fissures of Sylvius were thickened and rigid from the presence of calcareous plates in the walls. The wall of the right posterior cerebellar artery was thickened and rigid; its orifice at the basilar artery was only large enough to admit a pin, and at this point was an adherent thrombus on the distal side. The lumen of the whole of the right cerebellar artery was considerably diminished. The lateral and third ventricles were not remarkable.

In the outer (third) segment of each of the nuclei lentiformes (right and left) were two cavities each about the size of a pea. The walls were nearly smooth and non-pigmented. In the cysts was a clear fluid.

The posterior two-thirds of the right half of the cerebellum was very soft and of a grayish color. The posterior portion of this area were so altered that the cerebellar structure could not be made out. The an-

terior and upper portions showed the outlines of cerebellar structure, but the color was a uniform pale gray throughout. Numerous sections were made in the pons and medulla but nothing abnormal was detected with the naked eye.

The pons and medulla were hardened in Müller's fluid and alcohol, but owing to the cuts having been made in pons and medulla they curved outwards to such an extent as to make it impossible to get the axis of the pons and medulla in a straight line for imbedding and cutting. It was imbedded in celloidin and cut with the microtome. Of the pons the sections were very unsatisfactory owing to curvature of specimen. They were stained in carmine, and so far as they permitted of examination, I could discover no trace of softening or other lesion. Of the medulla fairly satisfactory sections were obtained. In these sections I could discover nothing abnormal.

Diagnosis: Unusually large frontal sinus; slight degree of oedema of pia; chronic endarteritis of cerebral vessels; obliterating endarteritis with thrombosis of right cerebellar artery; cysts from earlier softening in both nuclei lentiformes; recent softening of greater portion of right half of cerebellum.

Sequence of processes: Endarteritis of cerebral vessels; softening in nuclei lentiformes; obliterating endarteritis of right cerebellar artery with thrombosis leading to softening of cerebellum.

CASE IV. F. M., aged twenty-eight years, architect. I was called to see this patient on Sunday, March 4, 1883. Found him suffering with a very severe and agonizing headache. From the character of the pulse and from his general condition I considered him very ill, but not in any immediate danger. As he did not seem in a condition to answer questions, I elicited the following information from his father and sister: He dined Saturday about 5 P. M., with a good appetite, and was apparently well on going to bed. At 4 A. M. he called his father, and said he had a severe headache and could not sleep, and wanted some laudanum. He took thirty drops. In an hour or more he called again, and had thirty more. Soon after this he vomited, and was somewhat easier for a time; but by 8 A. M. his father sent me a note desiring me to see him as early as convenient. Before I could reach there I was summoned again, he seeming much worse.

I found him as stated in the beginning, and not thinking it advisable, in his peculiar condition, to give him any opiate, and the pain being very severe, I poured two drams of Squibb's ether on a folded napkin, and allowed him to inhale it. This I repeated in a few minutes. He soon went to sleep quietly, and his pulse and respiration soon became normal. I left him at 11 A. M. in this quiet sleep, expecting to see him again in the afternoon.

At 12.30 P. M. his brother, Dr. M., arrived, and on examining him found no pulse and no respiration. He died so quietly that his sister, who was watching him with the room darkened, did not know any change had taken place in him.

The following concerning his previous history will be of interest at this point. "He was never a very strong boy and never showed any especial liking for out-of-door exercise. He was bright, and read a great deal always." He went through Harvard College, graduating in 1876, and then studied architecture. In the spring of 1880 he had an attack of indisposition,

with some uncomfortable sensations in his head, but he seemed to recover completely on going South for a few weeks. During the last year of his life he suffered oftener with headaches but only occasionally severe. He always referred the pain "to the back of the eyes," but did not complain of any trouble in seeing. "They more usually came on about evening and were very frequently relieved by eating dinner, etc., or by a dose of bromide of potash, and only a few times has he ever required morphine." They were frequently accompanied with nausea and vomiting. There was never any mental disturbance known except once, for an hour. A few days before his death when on a railroad train, he called several things by wrong names, but was all right when he arrived at home that evening. This was noticed by a friend who was with him that afternoon.

His brother told me "he never saw any special cause for alarm, and never noticed any dilatation of pupils or difference between them. The pain never followed the course of any external nerve."

I saw him a few weeks before death when he had a severe attack of pain in his head, but it was quite readily relieved by simple means; and he remained at home two or three days, as he was evidently, at this time, needing a little rest, he having used his eyes a good deal in drawing architectural plans.

He was always quiet, gentle and uncomplaining; a lover of peace and harmony and fond of music and flowers, and of everything artistic. A genial, loving friend and companion.

The only accident that I can learn that he ever had was during his college life at Cambridge, by falling from his horse on a hot day. He arose, remounted, and rode two miles, dismounted, and wondered where he was. Nothing was ever observed following this mishap.

The following notes of the autopsy, by Dr. R. H. Fitz at 3 P. M., March 5, 1883, twenty-seven hours after death, are herewith presented:

Rigor mortis marked; body warm; skin purple in large patches. (Warmth and discoloration due to the body having been kept warmly covered.)

Head opened before examination of trunk. Calvaria thin. Dura mater injected, tense. Pia mater dry, in close contact with the brain; its veins contained very little blood. Longitudinal sinus held less blood than usual. Dura and pia unusually adherent along the longitudinal fissure; and a thick fibrous patch was present in the pia, near the longitudinal fissure posteriorly.

On removing the brain a superficial pigmented fibrous patch, the size of the finger-nail, was found at the base of the brain, on the left side, between the inner and middle temporal convolutions, replacing the gray matter. Cerebral substance everywhere anæmic and dry. Lateral ventricles distended, at least a third larger than usual, and filled with a clear, watery fluid; the ependyma thickened and firm.

A gray gelatinous tumor, the size of a filbert, was found upon the velum interpositum, in the median line, behind the fifth ventricle, in the region of the anterior commissure, on a level with the junction of the corpora striata and optic thalami. The tumor was easily removed from its surroundings, and on examination proved to be cystic. The wall was composed of fibrous tissue — the contents a gelatinous substance, homogeneous and transparent, with a feeble reaction of mu-

cine; numerous patches of small round cells were seen in the colloidal mass, on examination with the microscope. The structure and seat of the tumor suggested its origin from the choroid plexus; its position upon the vena Galeni explained satisfactorily the dropsy of the ventricles.

The blood-vessels of the trunk and its organs contained liquid blood. No other abnormal appearances were found on examination of the heart and lungs or on inspection of the abdominal cavity.

Diagnosis: Colloid cyst, presumably of choroid plexus; ventricular dropsy; yellow patch of basal convolution.

CASE V. Miss E. C., age fifty-one years. Had been for twenty years or more a very efficient nurse, and much liked by those who employed her. She came to my office April 20, 1889, and stated that her appetite was good, bowels regular, and that she slept well, and that she had no headache. Her manner was somewhat excited, and she showed marked symptoms of mental disturbance. She was incoherent in general statements, but replied to direct questions by *yes* or *no*. Could not remember names without great effort. I could not detect any irregularity in the pupils of the eyes or in their action, and no apparent paralysis of the different functions. I gave her a prescription and general directions, and told her I would see her in two days. I supposed until she left the house that she came alone, but subsequently learned that a friend was waiting for her, who accompanied her from Roxbury.

April 22d. I saw her at her friend's house, Warren Street, Roxbury, and found her sitting up and walking about. She said, "nothing ails me," but seemed glad to see me. Her conversation was more confused, and she had lost her memory for places and dates. On careful examination I found a slight paralysis on the right side in the upper and lower extremities; her tongue when fully extended showed a slight deviation to the right; and in walking I could see that she did not use her right lower extremity as she ought if there were no paralysis. No pain in head; appetite fair; urine normal.

April 23d. Being unable to see her on account of an obstetrical case, I telephoned Dr. Bolles to do so, and he found her in bed in an unconscious condition.

April 24. I found her comatose, and breathing in a labored manner with a slow, feeble pulse.

An examination of the urine resulted as follows: Specific gravity, 1.030; acid; red yellow; strong; quantity, normal; urea, nearly double; other salts, normal; albumen, none; sediment, considerable, (mostly epithelia of all kinds, urates and a few white corpuscles); *no casts*.

Diagnosis: Brain tumor of the left hemisphere, anterior lobe.

She remained in this condition until the morning of the 25th, and passed away in a comatose condition. I wrote to Mr. A. L. Calder, of Providence, R. I., at whose house she had been for a year or more, to learn how long she had been ill, and received the following reply:

PROVIDENCE, May 27, 1889.

DEAR SIR:—Yours of the 24th inst., asking for information touching Miss C's previous illness, is received.

The first symptoms we now recall were about six weeks before her death, when she complained of a peculiar headache and failure of memory, which latter she would laugh at herself, and so it failed to make any impression upon us. This was followed by a fatigued, languid manner and ac-

tion, which we attributed to her care and anxiety for my daughter Margaret, who was quite seriously ill; and in order to relieve her of that, we hired another nurse, and soon thought she was improving, although the occasional failure of memory is now remembered.

But it was not until the day before she accompanied me to Boston that we thought of her being seriously ill, when she had what she called a dizzy spell. Just what it was like we do not know, for she was alone at the time. My daughter noticed that something had occurred, and insisted upon her going to bed, which she reluctantly did, but not to stay long, for she soon appeared in the library, saying that she was all right. She continued about her household duties during the day, and appeared at breakfast Thursday morning, when it was plain that she was not all right, and that her failure of memory was rapidly increasing. So I prevailed on her to accompany me to Boston, that she might be with her friends, as owing to the illness of my daughter, we could not care for her as we desired.

On the way to Boston her memory failed so that she could not tell me where she wished to go, but pointed out the ear that would take her to her friend's house in Roxbury, where I found, after some inquiry, the house of this friend, and left her there. Yours respectfully,

A. L. CALDER.

The autopsy was performed, forty hours after death, by Dr. H. W. White, of Roxbury, and the following is his report:

Female, fifty-one years old; fleshy, two hundred pounds, rigor mortis well marked. No discoloration. Head opened first, as the symptoms were mostly cerebral. Head large; scalp very thick; veins very full. Pia mater not adherent; normal in appearance.

On opening the cranial cavity an accidental cut through left temporo frontal region was followed by a gush of clear, yellow serum. (Cut was due to great pressure of brain against skull, or special softening at that point, or both.) On base of left frontal convolution was a noticeable yellow tinge. Left frontal lobe was soft, and fluctuating on palpation. Section of left frontal lobe opened into a cavity, fully two inches in diameter, filled with yellow serum; walls were reddish yellow and gelatinous, as were the trabeculae. Probably three or four cysts made up the tumor. One remained intact; the rest collapsed. The tumor mass, one hour later, shelled out from the brain mass, and stood alone. Lateral ventricles fairly normal; left ventricle prolonged forward.

Microscopic examination showed nothing but serum and trabeculae of a fibrous nature, very vascular.

Kidneys showed no signs of disease.

This case is interesting as bearing out the diagnosis made forty-eight hours before death, and as showing the absence of pain, in marked contrast to Case I.

#### OPERATIONS FOR CORRECTING THE DEFORMITY DUE TO PROMINENT EARS.

BY GEORGE H. MONROE, M.D.,

Surgeon to the Out-Patients, Boston City Hospital; Surgeon to the Century Hospital; and Lecturer on Operative Surgery at the Harvard Medical School.

I do not propose in this paper to discuss the question as to the desirability of doing an operation for the correction of this deformity; but shall assume that any operation, at once simple and safe, which bids fair to accomplish this result, is justifiable. I have oper-

ated upon five cases in all; and I take the liberty of reporting them to you this evening, and of laying before you, for your consideration, the conclusions to which I have come.

CASE I. In 1887 I was asked by Dr. Morton Prince to examine the ears of a little girl three years of age, with the view of devising some apparatus to keep them back by pressure. The father of the child had made a contrivance, consisting of a half-circle of spring brass wire, which passed over the child's head, and terminated at each extremity in a pad to rest upon the ears. This apparatus had been faithfully applied for months without much benefit. The difficulty was that the pads could not always be kept in place.

The deformity in this case was complicated by the dropping over of the ears at the top. This was more marked on one side than on the other. Though an operation was spoken of, it was decided to try for a while longer the effect of pressure. Having taken a plaster cast of one ear in its corrected position, I fitted wire loops into the various depressions, and connected these with one end of the spring wire which went over the top of the head. I wished to experiment with this method on one ear at a time. The task of fitting these wire loops properly was a tedious one; and after it was all done, I was disappointed to find that, while the plan might have been suited to an adult ear, it was of comparatively little use for that of a child; for the cartilages were so soft and pliable that they offered too little resistance, and the wire loops were, therefore, easily dislodged.

I then gave up that plan, and tried another. At each end of the brass wire which passed over the head I attached a circle of wire large enough to completely surround the ear and so placed that when in position, its centre would be opposite the central point of the ear. This circular loop I strung with white worsted, somewhat after the plan of a tennis-racket. I thus had a very simple apparatus, consisting of the bent piece of flattened brass wire, passing over the head, and ending on both sides in racket-shaped extremities.

I then gave up that plan, and tried another. At each end of the brass wire which passed over the head I attached a circle of wire large enough to completely surround the ear and so placed that when in position, its centre would be opposite the central point of the ear. This circular loop I strung with white worsted, somewhat after the plan of a tennis-racket. I thus had a very simple apparatus, consisting of the bent piece of flattened brass wire, passing over the head, and ending on both sides in racket-shaped extremities.

Fig. 1.

This contrivance was tried faithfully, off and on, for several months; but at the end of this time we could not see any great improvement in the position of the ears.

CASE II. While these experiments were going on, a man with very prominent ears came to me at the Boston Dispensary (February 28, 1888), and expressed a wish that I should do an operation upon his ears, to keep them back. He said that he was greatly

annoyed by boys and others on the street, who ridiculed him on account of his deformity. The cartilage in this case was so stiff that I thought it best to excise a portion of it. Having made an elliptical incision behind the ear, I removed a piece of skin and of cartilage of corresponding shape and size. The axis of this ellipse was vertical, that is, parallel with the adjacent side of the head. All this was done from the rear, and the skin on the anterior surface of the ear was not interfered with. The cut edges of cartilage were united by deep sutures, and the skin stitched together over them. An antiseptic dressing was applied and the ear was bandaged firmly back against the head. In this operation I was assisted by Dr. Baldwin.

Although the wound did not heal by first intention, yet it did not gape, and when the scar had formed, the position was excellent.

In spite of the patient's assurance that he would have a similar operation done upon the other ear he did not return at the appointed time; and I have not seen him since. He probably dreaded the pain of another operation, for under no circumstances could I prevail upon him to take either.

Although the result in the case of the ear operated upon was all that could have been desired, so far as keeping the auricle back against the head was concerned, yet there were certain features about this operation, which I did not wholly like. There was formed a vertical fold of skin on the front aspect of the ear where the edges of cartilage had been brought together. Though this was not a serious objection, yet the ridge was to a certain extent a disfigurement.

Another noticeable feature was that the cartilage required a long time to heal. However, on the whole, I considered the operation a very successful one, as did also the gentleman who saw the case.

Later, while thinking over the operation and its results, I came to the conclusion that although a pinna of strongly resistant cartilage, as in the case just given, cannot be held back for any length of time without some operation upon the cartilage itself; yet it seemed that, in cases where the cartilage was soft and more pliable, the excision of an elliptical piece of skin only from the back of the ear, and stitching together the edges of the gap thus left, would be much simpler in the way of an operation and quite as efficient in holding back the pinna without causing any unnatural folds on the exposed aspect of the ear.

CASE III. In January, 1890, I had the opportunity of trying this method on a little girl, one year old. Both ears were prominent, the right one especially so. Besides this, the right ear was turned over at its upper border, thus making a couch-shaped ear. It was decided to set this ear back so as to make it like the other. Dr. C. L. Scudder assisted me at this as well as at the subsequent operations. The elliptical piece of skin was removed from behind the ear, the edges of skin brought together, and now nine months after the operation, there has been no sign of return of the deformity, and the mother expresses herself as greatly pleased with the result.

The success of this case induced the parents of Case I to consent to an operation, and both ears were treated by the excision of an elliptical piece of skin, as already described. The result was good and now, eight months after operation, the parents are well satisfied with the position of the ears.

CASE IV. A little girl of five. The right ear was

larger than the other, and projected unduly from the side of the head. Excision of a large elliptical piece of skin from behind the ear. Two months after the operation, the ear was well back: This case has not since then been heard from.

CASE V. A boy of nine. Ears very prominent. A large ellipse of skin from behind each ear removed, and now, two weeks after the operation, the wounds are thoroughly healed and the scar is quite firm.<sup>1</sup>

Fig. 2.

Fig. 3.

I was not aware until a few months ago that any operation for the relief of the deformity in question had ever been recommended or performed, though I thought it not unlikely, on account of the frequency of the deformity and the apparent simplicity of its mechanical correction. I soon learned, however, that several medical gentlemen in Boston had had cases under their charge, but I did not hear as to their methods of operating or results.

My attention was also called to an article by Dr. W. W. Keen, of Philadelphia, in the *Annals of Surgery* for January, 1890. Dr. Keen there describes an operation which he performed upon a boy of nineteen, with satisfactory results. Having excised an elliptical piece of skin from the back of the pinna, "a long, narrow piece was removed from the cartilage itself, V-shaped on cross-section, like the furrow of a plough." This gap in the cartilage was vertical, and being V-shaped, allowed the outer part of the pinna to be swung back towards the head upon the anterior hinge of skin (for the skin on the front of the ear had not been interfered with).

In his article Dr. Keen refers to an operation by Dr. Edward T. Ely,<sup>2</sup> of New York. The case was that of a boy aged twelve. Dr. Ely removed an elliptical piece of skin and cartilage from each pinna. The piece removed included the whole thickness of the pinna, that is the skin in front and behind and the cartilage between. The result was said to be excellent.

The operations therefore for the correction of the deformity in question are of two kinds; in the one the skin and cartilage are excised, and in the other the skin only.

#### OPERATIONS BY EXCISION OF SKIN AND CARTILAGE.

These operations appear to be called for only in cases where the cartilage is stiff, and they are therefore applicable principally to adults. Unusual twists or turns in the cartilage, thus causing special and unusual deformities, call for special modification in the technique of operation. One should, however, before he attempts

<sup>1</sup> These two drawings are made from photographs, of which the first was taken about one year before the operation and the other about six weeks after it. Since the healing of the wounds the child's ears have been bandaged only at night.

<sup>2</sup> Archives of Otolaryngology, 1881, vol. x, page 97.

any operation upon the cartilage for the correction of any deformity bear in mind the low regenerative power of that tissue, and he must therefore expect to wait patiently for the healing process to be complete.

It seems almost impossible that an operation upon the cartilage can be performed, which will leave no trace in the way of scar or unnatural prominence or depression on the outer aspect of the ear. I have already referred to the vertical fold of skin present in my case (Case II). If the elliptical piece comprises the whole thickness of the ear (Ely), a scar, more or less visible, is inevitable. If a V-shaped vertical groove is made in the cartilage from behind, and the part of the ear outside of this bent back against the head (Keen), a vertical ridge representing the angle in the cartilage must make its appearance on the outer aspect of the ear. These slight disfigurements which might be called "substitution deformities" will probably grow less and less noticeable as time goes on; but they must ever be drawbacks to the success of any of these operations. In spite of them, however, in certain extreme cases of unduly prominent ears in adults an operation upon the cartilage would seem to be justifiable and will probably give, on the whole, very satisfactory results.

In all cases the piece removed from the skin of the ear should be somewhat larger than that removed from the cartilage.

#### OPERATION BY EXCISION OF SKIN ALONE.

This method appears to be applicable to all those cases where excision of the cartilage does not seem to be necessary. The shape of the ellipse of skin to be removed from the back of the ear will vary to a certain extent with each case. Undue prominence of the ear at any one point should call for the resection of a specially broad piece of skin at that point. The incision to be made in the ordinary prominent ear, when the ear projects below as well as above, is shown in Fig. 4. The stitches are represented properly applied and ready to pull tight and knot.

In cases where the ear projects particularly at the top, while the lower part is normal (and this seems to be the next frequent variety of the deformity), the resected portion should be broadest above; while in the rare variety of the deformity where the lower part of the ear is particularly prominent the portion resected should be broadest below. In all cases the inner incision should be close to the bottom of the sulcus

where the skin of the back of the ear joins that on the side of the head.

The operation may apparently be performed in suitable cases at any age with success; though probably the earlier in life it is done the better will be the ultimate result. Either is required and the services of one good assistant. When under the anæsthetic the patient should be turned so that the ear requiring operation is uppermost. The scalp is then covered with sheet rubber and the field of operation cleaned with ether and corrosive sublimate. The piece of skin to be removed having been carefully mapped out it should be dissected off. The sutures should then be inserted in such a manner that when drawn tight the deformity is satisfactorily corrected, and rather more than corrected, so that the ear lies rather flat against the head. It may be necessary, for the sake of changing the axis of the ear, to insert the stitches, *diagonally*, from one skin edge to the other.

In case the operation is to be done on one side only, the two ears should be compared from time to time. When everything is satisfactory the sutures should be tied, and iodoform powder dusted along the line of incision. A temporary dressing is now to be applied in case the other ear is to be operated upon and the patient is turned upon the other side. The operation is then done on the second ear, both ears being compared from time to time. A layer or two of iodoform gauze is then placed back of each pinna, and the ears pressed firmly against the head by a bandage.

The operation is one of extreme simplicity, the only difficulty being in resecting a piece of skin of the proper shape and size and in properly placing the sutures. As the cartilage tends to regain its old position somewhat after the operation, a broad piece of the skin should be resected; that is, a piece equal in breadth to more than half the breadth of the back of the ear. As for suture material I have thus far used silk, and have removed them from the third to the sixth day. When I feel sure that I can get catgut, which is thoroughly aseptic, I shall use that by preference. A bandage ought to be worn for a period from ten days to two or three weeks. As a precautionary measure it is desirable that at night some sort of bandage or night-cap should be worn for several months to take the strain off the cicatrix, and prevent the patient from forcing the pinna forward by turning on the pillow.

The hearing is apparently not affected by this operation, and I am told by specialists that it cannot do harm in this respect.

The possibility of a resulting eczema has been suggested to me and should be borne in mind in case the patient has an eczematous tendency.

The scar is usually small and is mostly concealed by the pinna which is drawn back over it.

A sufficient length of time has not yet elapsed to enable me to state definitely that the correction of the deformity by resection of the skin alone is wholly permanent. I feel confident, however, that, when enough skin is removed and the ear is kept back until the cicatrix is mature, and possibly somewhat longer, return of the ear to its original degree of deformity is impossible.

THE *Obstetric Gazette*, which has for some time been published at the office of the Cincinnati *Lancet-Clinic*, is to be united with that paper, making one journal instead of two.

## RECENT PROGRESS IN OBSTETRICS.

BY CHARLES M. GREEN, M.D.

## ASEPSIS IN NORMAL LABOR.

VERCHÈRE<sup>1</sup> (Paris) is no longer satisfied with the aseptic management of parturition at present recommended by the authorities of the day, but advocates the following remarkable procedure: Beginning four weeks before the expected date of labor his patient is required to have twice daily a vaginal injection of a 1:1000 sublimate solution. In the last week, however, the injection is ordered only once in two days, the patient in the intervening time having a tampon of iodoform gauze placed in the vagina. When the pains begin, the tampon is withdrawn and a vaginal examination made. If everything promises a normal labor, a fresh tampon is placed and allowed to remain in the vagina until pushed out by the head. On the completion of the labor the vagina is washed out with sublimate and a tampon again inserted, which is changed the next day, but thereafter every other day, and finally every third day: an iodoform or sublimate compress is also kept over the vulva.

[This method may well be called asepsis gone mad: and yet it involves one principle of value,—infrequency of vaginal examination during labor. Every time the examining finger touches the patient, the possibility of infection is increased: and the best teachers are advocating the greatest possible restriction in vaginal touch. With increasing skill in abdominal palpation, the necessity for internal examination progressively diminishes, and with it also diminishes the possibility of septic injection.]

LEOPOLD and PANTZER (Dresden) have written very much to the point on this subject in a paper on "The Restriction of the Internal, and the Greatest Possible Use of the External, Examination in Obstetrics."<sup>2</sup> The paper is too long for satisfactory abridgment in this report; but the purport is well expressed by their sub-title, "Contribution to the Prevention of Puerperal Fever." The authors show in their paper how much may be learned by external palpation with the practised hand, and how much internal examinations may thereby be restricted; and they further show by statistics that, in proportion as the number of vaginal examinations diminishes, the per cent. of fever-free convalescences increases.

A great point will be gained when it is fully realized that the danger of infection lies not so much in the patient as in the attendants; when it is learned that much of the energy displayed in disinfecting the patient had best be directed to subjective asepsis. Then the parturient woman will be subjected simply to the cleansing bath and to the single corrosive douche at the beginning of labor, and to the occasional bathing of the external genitals with an antiseptic solution during and after the labor. But the greatest possible care will be expended by medical attendant and nurse on their hands, instruments and utensils brought in contact with the patient; vaginal examinations will be made as infrequently as an intelligent management of labor will allow, and thus will the frequency of puerperal infection grow beautifully less.—*REF.*]

## THE INDUCTION OF PREMATURE LABOR.

AHLFELD<sup>3</sup> (Marburg) analyzes the results of 118

cases in which premature labor was induced either by himself or his assistants: of this number 103 have fallen within the last seven years. In 111 cases labor was induced on account of pelvic deformity: in seven cases on account of some maternal sickness. The results to fetal life are as follows: Of the 121 children (three cases of twins) 102 were born alive and 19 still; 18 died during the first twenty-four hours, and nine more in the first ten or twelve days. There were discharged with the mothers at the end of convalescence 75, or 62 per cent.

Of the mothers only one died as a result of labor: four others died of affections on account of which labor was induced, or of complications incidental to those affections, that is, eclampsia, tuberculosis, heart-failure. Hence of 111 women, in whom labor was induced on account of contracted pelvis, only one died in consequence of the induced labor, that is 0.9 per cent.

The convalescence was non-febrile in 75 cases out of 109.

As to methods, Krause's was generally employed, — the introduction of a flexible bougie — sometimes preceded by preparatory treatment and sometimes not. The various preparatory methods employed (which in some few cases were in themselves alone effective), were the introduction of the colpeurynter, tamponade of the vagina or cervix, dilatation with tents, hot douches, and the alternating hot and cold douche. Frequently Krause's method would excite contractions; but the pains would remain very feeble. In such cases the following procedures were of assistance: separation of the lower segment of the foetal ovoid with the finger; Tarnier's tampon; rupture of the membranes before complete dilatation of the os uteri; a full bath with subsequent sweating; bi-manual version.

As a result of his observations and experience Ahlfeld has come to the following conclusions:

(1) The induction of premature labor in contracted pelvis maintains its place among fetal-life-saving procedures notwithstanding essential improvements in the results of Cæsarean section.

(2) Krause's method can be successfully carried out in private houses; but the chances of success are far greater in a lying-in hospital.

(3) The induction of labor must be deferred to as late a period in the pregnancy as possible.

(4) The lowest limit of pelvic contraction for the induction of labor must be a conjugata vera of seven centimetres [2.8 inches].

(5) The artificially induced labor should resemble a normal labor in its course as nearly as possible.

## THE ELIMINATION OF MORPHIA IN HUMAN MILK.

To test the effect on nurslings of morphia administered to the nurse, PINZANI<sup>4</sup> (Bologna), gave to twelve nursing women once or several times (at six-day intervals) three to five centigrams of the drug per diem. These women suckled thirty infants, of whom some were only a few days old, and one of whom was premature and brought up in a convulse. All the children remained perfectly well, and manifested no effect of the drug. The same negative results attended similar experiments with kaulanum. Moreover, chemical examinations of the milk for morphia with sensitive reagents gave negative results. Pinzani therefore concludes that morphia, in therapeutic doses, is not eliminated by the milk.

<sup>4</sup> Separatabruck: Centralblatt für Gynäkologie, 1890, No. 36.

<sup>1</sup> Labellio M.G., 1890, No. 9; Centralbl. f. Gynäkologie, 1890, No. 37.

<sup>2</sup> Archiv für Gynäkologie, 1890, xxxviii, 2.

<sup>3</sup> Centralblatt für Gynäkologie, 1890, No. 30.

[Notwithstanding this experience, it does not appear safe to believe as yet in the author's conclusions. In the first place, the fact that the milk of twelve women was divided among thirty children may explain the apparent absence of effect on any one of them. Moreover, other observers have reached different conclusions. Unless memory fails, one authority has observed the effects of morphia in the infant, when exhibited to the nurse in doses of one-tenth of a grain. Until the subject has been pursued further, therefore, it would be wiser to give opium in repeated doses to nursing women with extreme care.—*REK.*]

#### EXTERNAL VERSION WITH THE SECOND TWIN.

It is well known that the second twin, after the birth of his fellow, often assumes an oblique or transverse position, and presents the shoulder; that is to say, it fails to maintain its original longitudinal position, owing, apparently, to the relaxed condition of the uterine and abdominal walls. The careful obstetrician, realizing this possible misadventure, will seek to prevent it by promptly securing the fetus in its proper longitudinal position, until the re-awakening pains shall cause the head or breech to descend and engage in the superior strait; this may be done, when the interval of uterine inactivity is not long, by the hands placed on either side of the uterus. When the delay is more than a few minutes, the same end may be secured by padding the uterus on either side with compresses and adjusting a binder. Granting, however, that the malposition has occurred, how best may it be rectified? In a small proportion of cases, the contracting uterus will bring the long axis of the child into relation with its own; in other words, spontaneous version will occur; but this fortunate event cannot be depended upon, and prompt action is desirable in order that the shoulder may not become firmly engaged in the brim.

BROSIN<sup>6</sup> (Dresden) points out the ease and advantage of external version in these cases. With a flabby uterus and relaxed abdominal wall the lower fetal pole may readily be brought to the brim by external manipulation, especially if the amniotic sac is unruptured; and even if the membranes have been ruptured, external version will usually succeed, if powerful pains have not driven the shoulder into the pelvis. The advantage of this method over the more customary internal podalic version is pointed out by Brosin to be two fold: diminished risk of sepsis, and avoidance of a possible detachment of the placenta. Should exclusively external manipulation fail, bipolar version should next be attempted, and failing this, internal version.

#### THE CHANGE IN SIZE OF THE CHEST AND ABDOMEN DURING THE LYING-IN PERIOD, AND THE EFFECT OF THE BINDER UPON THEM.

HERMAN<sup>7</sup> (London) has read on this subject, pointing out that three reasons are commonly given by medical men and the laity for the use of the obstetric binder in puerperal convalescence, namely: (1) That it gives comfort; (2) that it counteracts the injurious effect of the sudden lowering of the intra-abdominal blood tension consequent on the emptying of the uterus and cessation of active muscular contractions; (3) that it keeps the waist measurement small and pre-

serves the figure. To test the truth of the third reason he caused measurements to be made in the General Lying-in Hospital, during the first ten days of convalescence, of the circumference of the lower part of the chest at the level of the ensiform cartilage, and also midway between this point and the umbilicus. He found that these circumferences diminished during the ten days rather more than an inch; that this diminution was not modified by age; that it was practically the same in primiparae and multiparae. To test the effects of the binder he then compared the measurements of three sets of patients, — first, those having a binder as ordinarily applied; second, those having no binder; and third, those in whom special attention was given to keeping the binder always firmly applied and tight. It was found that the diminution in the size of the lower part of the chest was practically the same in each of these three classes. Herman therefore concluded that the ordinary binder has no effect on the waist measurement of the patient; that the sole utility of the ordinary binder is to give comfort. In regard to the second supposed advantage of preventing the injurious effects of suddenly lowering the intra-abdominal pressure, the reader pointed out that the binder was not usually applied until after the time at which the lowering of pressure takes place.

#### THE INTRA-UTERINE TAMPON IN POST-PARTUM HÆMORRHAGE.

Since attention was first called in these reports<sup>7</sup> to the use of the intra-uterine tampon for post-partum hæmorrhage, the method has been quite extensively employed and appears now to have many advocates.

ELSNER (Rochester, N. Y.) in a short paper<sup>8</sup> on atonic post-partum hæmorrhage, speaks well of the intra-uterine tampon, and reports favorable results in two cases. Dührssen appears to have first suggested the procedure over three years ago, and since then several papers have spoken highly of its efficiency and freedom from objection. At the tenth International Medical Congress (Berlin, 1890), AUVARD<sup>9</sup> reported having employed the method in sixty-seven cases, with a loss of five. In the discussion Dührssen reiterated his belief in the procedure and claimed that in the tamponade we have a reliable and harmless hæmostatic measure the most certain of all in hæmorrhage from atony and laceration. He had never seen an open hæmorrhage converted into a concealed one by means of the tampon and did not believe such a misadventure could occur, when the tampon is properly applied; the method was recognized as a harmless measure not only in Germany, but also in England and elsewhere. VON RAMDOHR (New York) had employed the tamponade four times after all other means had been exhausted, and the women were almost moribund. All his colleagues in New York were fully in accord with the method.

In a recent number of the *British Medical Journal* the subject was fully discussed, and more opposition was expressed than perhaps Dührssen believes to exist in England. Many leading men, however, believed highly in the efficiency and harmlessness of the measure.

The technique is sufficiently simple. The cervix is seized with forceps and drawn to the osium va-

ginae; the uterus should at the same time be supported *supra pubem*. The best material for the tampon is iodoform gauze (10 to 20 per cent.), cut into strips; but, if this is not at hand, strips of sterilized cloth will do very well. Long uterine dressing forceps, or placenta forceps, will serve to apply the tampon and no speculum is necessary. Previous to the application of the tampon the uterus and vagina should be cleansed with a corrosive douche. The tampon should be firmly applied from fundus to cervix; and, if there is bleeding from cervical or vaginal tears, the vagina should also be packed. The tampon should be left *in situ* only a few hours, in which time the uterus will have recovered its tonicity and contractions will have been excited by the presence of the tampon as a foreign body.

## Clinical Department.

### TWO CASES OF SUSPECTED ANEURISM OF THE AORTA.

BY F. I. KNIGHT, M.D.

In the first of these cases the autopsy confirmed the diagnosis, and in the other failed to do so.

**CASE I.** The patient was seen January 31, 1889, for the first time. He was thirty-nine years old; a freight-train conductor; was usually strong and well. His physician thinks he has had syphilis. In April, 1887, he experienced a violent strain of the left arm in moving a switch. There has been no pulse in left radial since that time. There is no record of any examination before this. For a year there was severe pain and weakness of the left arm. In August, 1888, was much exposed in bad weather, and took a severe cold, which resulted in a cough, which has since continued. Has not been able to work much since. Has been "wheezy" since October 20, 1888. Exercise makes breathing very hard. A little dysphagia since October 1, 1888. Severe substernal pain, radiating to the left. Pulse 68, regular, in right radial; cannot be felt in left. No dullness on percussion of chest. No murmurs over heart or vessels. The respiratory murmur was of equal intensity over both sides of the chest. There was a short, deep, coarse, expiratory sonorous rale heard over the sternum and near it on both sides. There was no difference in the pupils of the eyes. The movements of the vocal cords were normal.

The diagnosis was made aneurism of the aorta? of course with the interrogative. He was put upon the iodide of potassium in increasing doses, and perfect rest was ordered.

March 15, 1889, the following report was made by his family physician: "Mr. X. is better. I can now, for the first time in two and one-half years, count his pulse in left wrist. I could feel the pulsation there for the first time about two weeks ago. The stridulous breathing is not as marked, though it is troublesome yet. The dysphagia is much less. The sleep is disturbed by neuralgic pain, and there is some anorexia. He is now taking forty-five grains of the iodide of potassium three times a day, and is quiet in bed."

May 9, 1889, I saw the patient again. He said that he remained in bed about six weeks from the time of

his first visit to me, after that he kept quiet in the house till about ten days ago. He improved till he went out; since then the cough and dysphagia had been worse.

On examination I could feel slight pulsation in the left radial, and there was less sonorous rale in expiration near the sternum. Otherwise no change in the physical signs.

He got restless, and went to work in July as conductor of a freight train; worked well till January.

February 24, 1890, his physician wrote me as follows: "Mr. X. went along well, taking forty grains of iodide of potassium three times a day, until the last of December, when he began to complain of great pain in left side of neck, and in region of the heart. There was a fulness of neck above clavicle on this side. I was sent for January 4, 1890, and found him partially paralyzed on the right side, with loss of power to articulate. In a few days he recovered the use of his limbs, so that he could walk around the house. He could talk, though not very well, and often could not say the word he wanted. February 22d he had a recurrence of the attack, but is a little better to-day."

The patient took no iodide after December, 1889, but had taken forty to fifty grains, three times a day, from January 31, 1889, till that date, with an omission of a few days on account of gastric disturbance. He suffered severe pain under the left clavicle, extending up the side of the neck, which increased in severity during the latter months of his life. In March an attack of influenza aggravated all his symptoms, especially the difficulty in speaking.

The pain became so severe that early in June he was put upon opium in full doses, and he improved so that he rode about town in July and August without increase of pain; and one day rode eighteen miles without apparent ill result.

About June 10th a pulsating tumor appeared under the left clavicle, which constantly increased in size till his death.

August 25th he was riding, and stopped near home to witness a ball game. He hawked up a mouthful of blood; was driven home within three minutes, fainted as he was taken from the carriage, but recovered enough to vomit as soon as he was taken into the house. He vomited a large quantity of blood. He was in a state of collapse and pulseless, when the doctor arrived. During the night he rallied, so that in the morning he was warm, with a faint pulse and quite cheerful. Two days after he had a large dejection of coagulated blood from the bowels.

August 29th, four days after first hemorrhage, he vomited blood again freely, and died in about two hours.

His appetite and digestion were always good, and he maintained his usual weight.

At the autopsy the stomach was found full of clotted blood. There was a large aneurism of the arch of the aorta, which showed a small secondary pouch just at the origin of the left subclavian artery. There was a large perforation of the esophagus about an inch above the level of the bifurcation of the trachea, and also an ulceration very nearly through the trachea about the same distance from the bifurcation. The heart seemed rather large; there was no valvular disease.

The case was interesting in several respects. The mode of origin would naturally challenge one's atten-

<sup>1</sup> Reported at the meeting of the Boston Society for Medical Improvement, November 24, 1890.

tion. Did syphilis act as a predisposing cause? It may have, though there was nothing post-mortem to suggest it. Did strain act as an exciting cause? The patient's symptoms certainly date from that accident. Did obliteration of the left radial pulse occur at the time of the accident? We cannot be sure about this, for he had not been examined previously to this.

Did the treatment have anything to do with the patient's temporary improvement? Rest certainly did. There was nothing in the appearance of the aneurismal sac to indicate that the iodide of potassium had any effect locally.

The cause of the improvement in the left radial pulse was probably due to the condition or position of the little pouch near the origin of the left subclavian. The improvement in the dysphagia was probably due to a diminution in tension of the large sac by rest. The head was not examined, but the right hemiplegia was undoubtedly embolic.

CASE II. The second patient was seen by me October 9, 1890. He was fifty-eight years of age, and had always been well previous to his present sickness. He had lost the right forearm by an accident a few years before. His present sickness began with dyspnea and cough last May. The dyspnea had gradually increased, and there had been orthopnea two months. There was a little dysphagia. Pulse 108, soft, quick, regular. Dulness over upper part of sternum, and in the first and second spaces to the left. There was marked pulsation in the second left intercostal space near the sternum. Bronchial respiration near the sternum at top of left lung, and at top of left shoulder. Elsewhere in left front the respiratory murmur was feeble. Systolic murmur over left chest, most marked in left interscapular region. Superficial veins of integument of lower part of chest distended. Feet and ankles oedematous.

Complete rest was ordered, with the iodide of potassium. He gradually grew worse and died October 25th.

At the autopsy a very large tumor was found, compressing the trachea, oesophagus, and apex of the left lung.

In this case the diagnosis of aneurism seemed more certain than in the previous one, inasmuch as one had in addition to the pressure signs also those of a marked pulsation in the second left intercostal space. But the one crucial test of an aneurism failed, that is, there was no expansion of the swelling under one's fingers, laterally as well as vertically. The tumor proved to be a malignant lymphoma.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL OBSERVATION.

C. F. BULLMAN, M.D., SECRETARY.

REGULAR Meeting, Monday, November 3, 1890.

DR. JOSEPH STEADMAN read a paper on

CEREBRAL TUMORS, WITH CLINICAL CASES.<sup>1</sup>

DR. WHEBBER: I have been very much interested in the review of cases, and having seen two of them I was very much interested in hearing the others. The second

<sup>1</sup> See page 276 of the Journal.

case reported, which I saw, was a very interesting one, as showing so few of the symptoms of brain tumor. In that case there was, I think, nothing but headache as a general symptom preceding the last serious illness, and that headache disappearing and the patient being able to go out and take photographs. Headache is one of the most common symptoms in brain tumor, sometimes the most marked of all the symptoms, sometimes very excruciating, eclipsing and concealing all the other symptoms, the patient and his friends giving all their attention to the headache which is so severe. Others of the general earlier symptoms are dizziness, and inability to walk straight, lack of coordination, nausea and vomiting. Sometimes the very first symptom that attracts attention is a loss of mental power or a change of disposition, the person acquiring a certain amount of irritability; if there is headache it is very likely to be assigned as the cause of the irritability and the change of disposition. Frequently there is a general loss of motor power, a person becomes weak without any special paralysis, without any weakness of one side more than the other, yet there is a decided loss of power. Those general symptoms will frequently, the one or the other or all of them precede the localizing symptoms; but here in the second case there was simply the headache. I think there was no change of disposition, no special staggering or dizziness and no nausea or vomiting, and no special motor weakness. Headache is not a good localizing symptom. The pain does not occur necessarily where the tumor is, but may be referred to other portions of the head. It depends upon how the pressure is exerted upon the nerves; it depends upon whether the pressure is exerted at the spot where the tumor is, or at a distant spot, whether a nerve is irritated which goes to some other region, so that the pain is referred to a part of the head distant from where the tumor is. When I saw this boy it was clearly a serious case. I was not called until the paralysis had occurred. That seemed to be caused by an attack of hemorrhage, as the autopsy proved. It was only by taking into account the previous headache and the previous symptoms that I could, I might say, guess there was a cerebral tumor. The rise of temperature and pulse toward the close of the disease was undoubtedly due to the hemorrhage.

It is very common after a hemorrhage into the brain, in fact, it is the rule, to have rise of temperature. First, there is likely to be for a few hours a lowering of temperature, and then a steady rise, the temperature in very serious cases rising continuously, in cases that are less serious rising for a short time, then remaining stationary, and in favorable cases, where the hemorrhage is not going to prove fatal, the temperature will go down again to normal; or if it is not going to terminate favorably, after the temperature has remained stationary for a short time it will rise again, so that undoubtedly the rise of temperature in this case was due to the hemorrhage.

The case in which plugging of the artery occurred was a very instructive one to me, and interesting from the fact that previously, in 1882, the patient had the symptoms which were mentioned; headache and a general feeling of discomfort, malaise, and weakness, being kept in the house for quite a while. At that time the possibility of a tumor was suggested, though I did not think that was it, and gave rather a favorable prognosis; I thought that he suffered from

a disturbance of the cerebral circulation, and that the typhoid fever, which he had had, debilitated him, and that this with his age gave rise to an irregularity in the cerebral circulation which produced the symptoms, which I thought might pass off, and it seems they did. He virtually recovered.

The instructive point in that case to me was that the autopsy showed the disease of the arteries, which might well have been the cause of disturbed circulation, and explains fully the reason for his discomfort in the head, the headache and the disturbance of mental power, whatever there was. It is a condition which is frequently found, undefined disturbances in the head of that kind which seem to be due to irregular circulation. Some authors I think assign this disturbance to digestion, and some to anæmia. It has always seemed to me it was neither one nor the other, but irregular circulation, that the brain was not properly nourished because of that irregularity, and hence the discomforts. Here we have an autopsy made six or seven years afterwards which clearly showed the cause for such disturbance. I am sorry that I have not the case fully in mind. I have not had time to look it up since I received the notice of this meeting. I think that during the last attack just preceding death there were symptoms interesting as local symptoms, which pointed to the medulla oblongata or the base of the brain as the seat of the disease. We could hardly call that a case of brain tumor. It was rather a plugging of the arteries and softening, although there was a suspicion at the time of its being an obscure case of brain tumor. I notice that the other cases are interesting also as having so few symptoms preceding the final outburst of the disease. We meet such cases occasionally, but they are not very common. There are almost always localizing symptoms which are more definite than those in these cases which Dr. Stedman has reported.

DR. R. H. FITZ: I remember the two cases Dr. Stedman has reported in which I made the examination, and I was very much struck at the time with the rapidity of the symptoms. In one of the cases it was especially fortunate that an autopsy was made, because, for the relief of the headache, quite a large dose of laudanum had been taken. Although from the clinical history of the case it seemed unlikely that the laudanum should have occasioned the death, yet it was very satisfactory to find the evidences of an extreme degree of pressure in the brain, with a dropsical condition of the ventricles, and the presence of this tumor.

The occurrence of sudden and unexpected death in cases of cerebral tumor has also occurred to me in connection with two cases that I particularly recall. Many years ago a man was brought into the hospital who had been found dead in the loft of a storage warehouse, and it was thought that his death might have been the result of some violence, or suicidal act, but a satisfactory explanation was found in a diffuse glioma of the medulla through which this portion of the cerebro-spinal axis was enlarged to a very considerable extent, and was engorged with blood. It seemed to be a case of diffuse glioma, with congestion such as is not infrequent in very vascular tumors, and in so vital a portion of the axis it had been sufficient to paralyze respiration, for he died with evidences of suffocation. The other case was a portion of brain brought recently by Dr. Durell, of Somerville, who had been called upon to see this patient during the evening. She, having previously been in good health, was suffering from a

severe headache which was relieved by a small dose of morphia, but in the course of the night she died. There was found a large cyst of the cerebellum, which, probably, is to be regarded as the cause of her symptoms and death. It was the only lesion, at all events, that could be found.

Another point which occurred to me in connection with Dr. Stedman's cases is one which Dr. Webber has already referred to. The case of cerebral softening, I think, it is hardly fair to call a case of cerebral tumor. It seems to me that this remark might also apply to another of the cases where there was evidently cerebral hæmorrhage without there having been presented, so far as I can learn from the paper, any evidence that the hæmorrhage was from the tumor.

One other point that I think is a very important one, which Dr. Stedman's paper suggests, is that cerebral tumors even though they are to be recognized before death are not therefore cases where one should straightway proceed to an operation for their removal. The case of the cystic tumor of the choroid plexus with dropsical dilatation of the ventricle was one in point, and the diffuse glioma or gliosarcoma was another. This latter, in particular, represents a class of cerebral tumors where, even with localizing symptoms, the tumor often occupies a very large area, its limits are in no way defined, and the gross appearance and physical characteristics may resemble so closely that of the surrounding substance that there is no border line between what is brain and what is disease.

DR. BULLARD: I think Dr. Stedman's cases are particularly interesting because they relate to a class of brain tumors of which we have not heard so much of. We have heard a great deal of brain tumors with localizing symptoms especially with reference to brain surgery. I believe it has been found as far as we know that only about ten per cent. of brain tumors are operable even providing that we can say beforehand exactly where they are, that is, if we had every means of knowing all about them, only ten per cent. of all brain tumors are to be reached and safely removed by our present means. I think, therefore, that those brain tumors which are not operable have been rather lost sight of, and, what I may call the general symptoms of brain tumors, have been rather obscured, much accent being laid upon the localizing ones. The principal general symptoms of brain tumors are a half-dozen in number, — headache, vomiting, vertigo, optic neuritis, some mental disturbance or dulness of mind, and the general weakness which Dr. Webber alluded to. When those symptoms alone occur it is usually considered that a tumor cannot be localized, in other words, they may be caused by tumors in almost any part of the brain. In regard to headache, I think the localizing value of this symptom is very slight unless possibly in case of localized headache persisting a very long time. Certainly we have instances of localized headache in which the tumor was in an entirely different position from the position of the pain. I recall a case operated upon in 1887 in which there was very severe headache over the region of the eye and the tumor was found in the cerebellum, and there was no evidence of any circulatory trouble to cause the location of the pain. In regard to the case of atheromatous arteries, if I recollect the statement, that case had lasted five years. I think that is almost as long as any tumor with decided symptoms has been known to continue. Dr. Branwell reports a tumor of five years'

duration. Of course it is possible we may have them even longer, but, so long a duration as that, would be decidedly against the diagnosis of tumor, although it could not exclude it. On the other hand, I think that pain very frequently accompanies atheromatous arteries when the general tone of the system is from any reason lowered. I have seen a number of cases in which the pains of the head were shifting and quite severe and were apparently due to a change in the circulation due to atheroma of the arteries, and one of those cases was shown to be so by the autopsy.

In the first case that Dr. Stedman reports, I believe that the frontal lobe on one side was much larger than on the other. I should like to ask whether a microscopic examination was made with a view to determining the cause of the enlargement. It is well recognized that in certain forms of tumors the lobe in which the tumor is embedded is enlarged, and, this is thought by certain writers, to be due to chronic inflammation of the tissue in the neighborhood about the tumor, and it has been stated by them that evidence in favor of this view has been found in the form of certain cells. I should be glad to know if an examination had been made in that case and if the impressions of these writers had been confirmed, as it is still a vexed question.

There is one other point to which I should like to call attention in relation to these cases, and that is the very rapid changes which take place in the condition of patients with cerebral tumors, even putting aside the cases of hemorrhage. I think there is no doubt that most of the cases I have seen have been marked in the later stages, at least, by very decided changes in the pulse and the whole condition of the patient within a few hours occurring without any known cause, sometimes for the better and sometimes for the worse; changes in the character, strength and rapidity of the pulse, in the condition of respiration, and in the amount of consciousness present. These are probably due to changes in the circulation, in the amount of fluid in the ventricles, but the changes are sometimes very rapid and of a very serious character. It seems as though the patient were about to die, and yet in a few hours he may rally and in a few hours more be as well as before this condition commenced. I have noticed this particularly in the case of cerebellar tumors, but I think the same occurs also in cerebral cases. This makes the immediate prognosis a matter of extreme difficulty at times.

Dr. P. C. KNEVEL: I think this is a very instructive series of cases, as showing how very large tumors may exist all probability for a good many months without giving the slightest symptoms and then may develop either vague or only general symptoms of tumor, and go on rapidly to a fatal termination. It is instructive, too, in widening our knowledge in regard to tumors where the symptoms are clearly marked, and our diagnosis is debated, teaching us that we should always give in our prognosis a warning that the patient may suddenly become comatose and die. I have seen that in two cases where the patient, apparently going on very well, without any warning, suddenly developed coma. Dr. Bullard has spoken of one of the general symptoms of tumor for which we very often do not look; at least, in fact, one half of the recorded cases, I think there is no record of the symptom, and that is optic neuritis. On one of the importance of optic neuritis is recognized by every one, but I do not think that every

physician recognizes that there may be well-marked neuritis without failure of vision. I saw only last week a patient who is now totally blind with a post-neuritic atrophy, but a year ago when the symptoms first began to develop he went to Dr. Wadsworth who examined his eyes and found a well-marked neuritis in both eyes with a vision of twelve-fifteenth, after correcting a slight astigmatism. In every case of obscure cerebral disease we should make a point, I think, of examining the fundus for neuritis, not only once, but repeatedly, as it may develop late in the progress of the tumor.

Dr. FITZ has stated that in many of these cases surgical interference is impossible. In the infiltrating glioma, no matter where they are situated, an attempt at removal will probably do little good, and we must bear in mind in every case of tumor that diagnosis of the nature of the growth is exceedingly uncertain and that in ten per cent. or more of the cases recorded the growths are multiple, so that the estimate which Dr. Bullard has stated is certainly a high one as to the number of cases which can be successfully diagnosed and removed. There is, however, one point in regard to surgical interference I would wish to bring forward here. I saw a case only last week in which I advised surgical interference, not with the hope of removing the tumor, because the location is distinctly obscure, and what few symptoms there are, that give any hint as to the localization, seem to indicate that it is probably not easily accessible. In the cases of tumor with persistent headache, I think we should trephine, whether the tumor be accessible or inaccessible, whether a tumor be of a sort that can be removed or some malignant or infiltrating new growth, not with the hope of removing the tumor, but with the hope of removing the intracranial pressure, and thus relieving the headache, which, in these cases, may become intolerable, and which will not yield to any drugs. This treatment was, of course, suggested by the results in one or two cases (notably a case reported by Ross several years ago) of attempts to remove tumors where it was found that they could not be removed, either from their nature or from the fact that they extended more deeply and involved the base of the brain. This was advocated at Berlin most strongly by Mr. Horsley, who has done it successfully in four cases with the result of relieving almost completely the intense headache. Of course, the patient succumbs later, but the trephining proves of immense help in relieving his sufferings, and making him more comfortable. Simple trephining cannot be regarded to-day as a particularly dangerous operation. One point which I forgot to mention in regard to the question of the duration of tumors. Dr. Bullard has stated that they seldom exist longer than five years. I think there are certain cases, notably tubercular new growths in children, where the tumor becomes encapsulated, and where, if they exist in some neutral region of the brain, they may go on for many years without giving rise to further disturbance. In going over the records of a good many autopsies I have found several cases of tumors located perhaps in the tip of a frontal lobe, or the tip of the temporal lobe, or in one of the lateral lobes of the cerebellum, small, cheesy growths with a hard calcareous capsule where there was no history of symptoms, and it was supposed by the pathologists that these growths had existed a good many years.

I would like to mention two cases which I saw this

summer. One of them was reported by Oppenheim in the *Berlin Klinische Wochenschrift* for July. It is interesting from the fact that three months after a tumor was removed from the motor region of the brain, the woman was delivered of a healthy child born at term. The other was a case where I saw the preliminary operation of tying the carotid [case of Mr. Horsley]. The case was that of a man who ten years before was struck in the head by a cricket ball. After several years he began to have headaches increasing in intensity. On further examination I think there was a certain amount of neuritis, and a little vertigo, vomiting, headache chiefly frontal, and bi-temporal hemianopsia. Mr. Horsley diagnosticated either new growth or aneurism at the optic cloasma. The case was almost precisely similar to one reported by Dr. Weir Mitchell two years ago at the meeting of the American Neurological Association. I saw Mr. Horsley tie the carotid, and later he told me that he had cut down and removed a large piece of the frontal bone, lifted up the frontal lobes, looked down upon the optic cloasma where he found an aneurism about the size of a filbert. He put a piece of sponge down there to exert pressure, and, if possible, to produce a thrombus in the aneurism, put back the frontal lobes on top of it, and sewed things up. I am not sure whether he tied the carotid on the other side or not. When Mr. Horsley told me this some weeks after the operation the man was doing very well.

DR. STEDMAN: In regard to the microscopic examination of the hemisphere of the brain, I shall have to refer that to Dr. Fitz.

DR. FRIZ: My impression is that that was attributed to edema.

DR. H. W. WILLIAMS: If the Society cares to hear a few words more in regard to this subject I would say something in regard to a few cases which recur to me distinctly, as having reference to some of the points that have been made to-night, one of which is as to the duration. Of a very large number of cases that I have seen, I recall several which were of interest sufficient to fix them in my mind so that I can give some facts without referring to my notes. Two of these were cases of long duration, both in gentlemen of middle age, and the first case was seen with me by two gentlemen from New York of the highest distinction there, who agreed entirely with my diagnosis; but the gentleman lived six years. His family were discouraged at my unfavorable prognosis, which was concurred in by these gentlemen who saw him, and he went to several charlatans, who accomplished nothing. The case went on as I had said it probably would, with the loss of hearing, smell and taste, and he died at last in the hands of his family physician in a town not far from Boston. I saw the tumor, which was as large as my fist.

The other case was that of a gentleman of distinction in another State, who also lived six years and had the same course of events as regards loss of senses, and I saw the tumor in his case also, which was even larger than the one in the case I have mentioned.

Another case is interesting as having been placed, as I had said in making the original diagnosis, between the optic chiasma and the left eye-ball. A gentleman from a western State came and put himself and died under my care, living, I think, some two months after he came. He had considerable dull pain in the forehead, and about two weeks before he died the severity

of the pain was very much increased, especially as affecting the eye-ball. I then made the diagnosis of erosion of the roof of the orbit and pressure of the tumor upon the globe itself, which was verified at the autopsy. A tumor about as large as one-half of my thumb had eroded the orbital plate and rested upon the eye-ball, causing this intense increase of symptoms. The case would have been an admirable one for operation if cerebral surgery had been in the advanced state that it is at present.

Another case was that of a clergyman living in another city, brought by his physician, who was very much astonished when I gave the diagnosis of brain tumor; and showed him the ophthalmoscopic appearances, which were very marked in that case. It is interesting from the fact that when the physician asked me how long I thought the patient might live, I said: "It is impossible to predict, as very great range was found in these cases, and I should not say positively, but I should think six months might be a fair estimate." I afterwards learned that this clergyman went on with his duties almost uninterruptedly till the six months had expired. The doctor said to himself: "Dr. Williams was not quite right in his prognosis as to this case." He died, however, three days after the six months were ended.

Another case was that of a *confrère* brought from the western part of the State. The symptoms had not been very urgent. I made the diagnosis of probable tumor of the cerebellum, and the two doctors returned home. His attending physician wrote me in about three weeks, when he sent me the tumor, that his *confrère* went home without seeming to be injured by the journey in any respect, but within the next few days there was a very marked change for the worse. He died and a tumor was found in the cerebellum about the size of a pullet's egg. I thought these cases might be interesting, as having some definite facts in regard to duration; and some of them marked by rather slight severity of symptoms even when the course was rapid.

DR. WEBBER: In regard to the duration of tumors, I remember one case where there was an injury, I think a blow on the head, more than five years before death. There had been within a short time after the injury more or less disturbance, not enough to say there was a tumor, but discomfort, and it seemed as though the tumor must have been caused by that blow on the head. I think it was some ten years previous to death that the blow occurred. In regard to the pain, Dr. Bullard spoke of the tumor of the cerebellum. I saw a case which had been diagnosticated facial neuralgia, in which I made the diagnosis of tumor of the cerebellum. There was probably pressure on the fifth nerve as the cause of the pain.

DR. STEDMAN: As a matter of interest in the case of the gentleman Dr. Webber saw, there was an undoubted typhoid as shown by the condition of the abdomen which was tympanitic. There were also rose spots. The temperature was exceedingly low for typhoid, and the pulse was slow, but the symptoms which were found after death must have been going on at the time because he had some of the same pain that he had in his later days.

A BERLIN paper mentions as one of the results of the late Congress, the publication of four hundred engagements of marriage.

## SUFFOLK DISTRICT MEDICAL SOCIETY.

J. J. MINOT, M.D., SECRETARY.

STATED Meeting, Saturday, October 25, 1890, Dr. G. W. GAY, in the chair.

Dr. G. H. MONKS read a paper on

OPERATIONS FOR CORRECTING THE DEFORMITY DUE TO PROMINENT EARS.<sup>1</sup>

Dr. MORTON PRINCE: I had an opportunity to see three of Dr. Monks's cases, and I can testify that his results were very satisfactory. Two of them I did not see till after the operation was done, and therefore I do not know how bad the deformity had been, but when I saw them, one would never have suspected that any disfigurement had previously existed. The third case which I sent to Dr. Monks I had under my observation for a long time, and I hardly think that Dr. Monks has laid as much stress as he might upon the extent of deformity, nor upon the amount of correction which he has produced. When this child was about six months old I had a frame made to go over the head with two pads so arranged as to press upon the ears and keep them back. Now in this case, not only did the ears stand out, but they were conch-shaped, something, in a mild way, like a calla lily. Therefore, it was necessary not only to hold them back as a whole, but the outer rim had to be rolled back. It was difficult to accomplish this by means of a frame. After the child had worn the frame about a year and a half, I could not see any improvement whatsoever, and I brought the child to Dr. Monks with the idea that he might invent some kind of a frame which would work better. He experimented with different kinds of frames as he has said, but none of them was more effective than the original pattern, except that the frame with racket-shaped extremities was more easily retained in place. I did not think it advisable that an operation should be performed at that time, as the child was quite delicate, owing to what there was reason to believe was arsenic poisoning. For this reason we did not wish to submit her to etherization, etc. There was perhaps another and stronger reason, namely, that although Dr. Monks was very enthusiastic about the possibilities of the operation, the mother wished to wait until the first experiment had been tried on some one else. However, when the child was about four years of age I saw Dr. Monks's second case, and it was so successful that I advised the mother to have the operation performed. This was done and the operation has proved a great success. Not only are the ears held back, but the curling of the ear has been entirely corrected.

Regarding the technique of the operation I should say that the chief difficulty lies on its artistic side. It is a very delicate operation and requires a good deal of skill in the way of fitting, much like that of a tailor in fitting a coat. I should think, especially when the ears are conch-shaped, that it required a good deal of skill to so adjust the skin that the ear will stay back in place in the proper way. I myself think that the ears can scarcely be placed too flat against the head. I am inclined to think the position of the ears, like many other things, is a matter of fashion, and that the fashionable ear to-day is the one that lies back flat against the head. Perhaps by and by we will change our ideas and regard the prominent ear as the fashion-

able one, then perhaps Dr. Monks can devise a new operation which will make all these ears stand out again.

Dr. E. H. BRADFORD: Dr. Monks referred to a case I had, where I succeeded in fastening the ear back. The child had a large congenital naevus behind the ear throwing the ear forward. The operation was undertaken for the removal of the naevus, and in doing this I was obliged to take out quite a large piece of loose skin behind the ear, the result being that the ear was entirely corrected in position. I used the galvanocautery to destroy the naevus and in that way corrected the deformity.

Dr. HENRY O. MARCY: I am deeply interested in this subject, and am very glad to have heard the experience of the writer. I have done this operation only twice, and that, for a deformity of the cartilage as well as an undue prominence of the ear, and if this latter only exists I am quite sure that the writer of the paper will agree with me that it is not necessary to make a resection of the cartilage. The ear is only unduly prominent. I cannot see why this simple plastic operation, which is beautiful in its technique and without danger, does not answer every purpose. It is very beneficial to close the parts with a continuous buried tendon suture and seal the wound with iodoform collodion. This saves cumbersome antiseptic dressing. As there is no need of drainage, sealing ought to be, in such a wound, the ideal method, and I must think that it commends itself to your judgment, for it adds very materially to the simplicity of the after-treatment. The tendon suture aseptically applied is trustworthy; there are no stitches to be removed and no subsequent dressing is required. I believe this operation should be commended in a very considerable class of patients that has been overlooked. You all know how very sensitive at times certain persons, especially ladies, are about this so-called deformity.

Dr. F. B. HARRINGTON referred to the treatment of a case in which the cartilage of the ears was buried under the skin making the child appear as if the ears had been cut off. On examination the cartilage could be felt under the skin. The cartilage with a flap of skin was dissected out. Result was very satisfactory.

Dr. S. J. MIXTER described a new method of operating for the correction of undue prominence or size of the ears, no cartilage being removed.

Mr. EDWARD ATKINSON read a paper on

## THE APPLICATION OF HEAT AS A FACTOR IN NUTRITION (COMMONLY CALLED COOKING), ILLUSTRATED BY EXAMPLES.

## NEW YORK MEDICO-LEGAL SOCIETY.

## HYPNOTISM, THE MURDER, CHEMICAL EVIDENCE IN CRIMINAL TRIALS, ETC.

At a meeting of the New York Medico-Legal Society held January 15th, Mr. CLARK BELL, recently re-elected President of the Society, delivered his inaugural address, and reports were received from various committees. In the course of his address Mr. Bell stated that the membership now amounted to 862, an increase of 119 over that of last year.

The Committee on Hypnotism, Dr. E. MORGAN, JR., reported that, after a year's consideration of the subject, they regarded it safe to say that the following facts had been established:

(1) Hypnosis, or artificial trance sleep, is a subjective phenomenon, and may be self-induced through expectation alone, through fright, by religious ecstasy, or any enrapturing emotion.

(2) Hypnosis is not in itself a disease.

(3) Hypnosis is recognized in three stages—lithargy, somnambulism and catalepsy. The transition may be immediate.

(4) Hypnotism has been serviceable in medical and surgical practice, both as a therapeutic agent and in some cases as an efficient and safe anesthetic.

(5) The illusory impressions enacted by hypnosis may be made to dominate and tyrannize the subsequent actions of the subject.

This report is to be discussed at the February meeting of the Society.

The Committee on the Morgue urged that the organization of the New York Morgue should be made similar to that of Paris. The chief should be a physician of the highest ability, and he should have a corps of trained assistants. The importance of a morgue thus equipped and conducted as a factor in the detection of crime could not be over-estimated. The Society recommended that a committee be appointed to bring the subject before the municipal authorities.

Considering the present methods of procuring chemical evidence in criminal trials, both in the State and National courts, the Committee on National and State Chemists, DR. VICTOR C. VAUGHAN, Chairman, recommended the appointment of an official to be known as the National Chemist, in the service of the Government, with a salary sufficient to command the highest available talent. It also recommended the establishment of a laboratory to be at the disposal of the Government, or persons accused of crime, or the State authorities, under suitable regulations. In each State there should be a State Chemist and laboratory, and this, with the national office, it was believed, would greatly elevate the character and standing of expert testimony in the courts.

In addition to six Trustees, the following officers of the Society for the ensuing year were installed on this occasion: President, Clark Bell; 1st Vice-President, Judge H. M. Somerville; 2d Vice-President, Albert Bach; Secretary, W. C. Humphreys; Corresponding Secretary, Moritz Ellinger; Librarian, Dr. M. D. Field; Curator and Pathologist, Dr. J. C. Thomas; Chemist, Dr. H. A. Mott.

## Recent Literature.

*Hystéropexie abdominale antérieure et Opérations sus-pubiques dans les Rétro-déviationes de l'Utérus.* By MARCEL BAUDONIN. Paris. 1890.

If any one wishes to find a fairly complete résumé of the operation of abdominal fixation of the retro-placed uterus called here "hystéropexie," and of other intra-abdominal operative procedures which have for their object the cure of backward displacements, this work will repay perusal. It gives the history of "hystéropexie," a full description of the operation, indications and contra-indications, comparison with other operations for the same purpose, results and therapeutic value, the notes of seventy-eight cases by different operators, and finally a complete bibliography of the subject.

## Communications on Koch's Method.

### THE COMPOSITION OF PROFESSOR KOCH'S FLUID.<sup>1</sup>

SINCE I published, two months ago, the results of my experiments with the new remedy for tuberculosis many physicians who received the preparation have been enabled to become acquainted with its properties through their own experiments. So far as I have been able to review the statements published and the communications received by letter, my predictions have been fully and completely confirmed. The general consensus of opinion is that the remedy has a specific action upon tubercular tissues, and is, therefore, applicable as a very delicate and sure reagent for discovering latent and diagnosing doubtful tuberculous processes. Regarding the curative effects of the remedy, most reports agree that, despite the comparatively short duration of its application, many patients have shown more or less pronounced improvement. It has been affirmed that in not a few cases even a cure has been established. Standing quite by itself is the assertion that the remedy may not only be dangerous in cases which have advanced too far—a fact which may forthwith be conceded—but also that it actually promotes the tuberculous process, being therefore injurious.

During the past six weeks, I, myself, have had opportunity to bring together further experiences touching the curative effects and diagnostic application of the remedy, in the cases of about one hundred and fifty sufferers from tuberculosis of the most varied types in this city and in the Moabit Hospital. I can only say that everything I have latterly seen accords with my previous observations. There has been nothing to modify in what I before reported. As long as it was only a question of proving the accuracy of my indications, it was needless for any one to know what the remedy contained or whence it was derived. On the contrary, subsequent testing would necessarily be more unbiased the less people knew of the remedy itself. Now, after sufficient confirmatory testing the importance of the remedy is proved, my next task is to extend my study of the remedy beyond the field where it has hitherto been applied, and if possible, to apply the principle underlying the discovery to other diseases.

This task naturally demands a full knowledge of the remedy. I therefore consider that the time has arrived when the requisite indications in this direction should be made.

Before going into the remedy itself, I deem it necessary for the better understanding of its mode of operation to state briefly the way by which I arrived at the discovery. If a healthy guinea-pig be inoculated with a pure cultivation of tubercle bacilli, the wound caused by the inoculation mostly closes over with a sticky matter and appears, in its early days, to heal. Only after ten to fourteen days a hard nodule presents itself, which, soon breaking, forms an ulcerating sore, which continues until the animal dies. Quite a different condition of things occurs when a guinea-pig already suffering from tuberculosis is inoculated. An animal successfully inoculated from four to six weeks previously is best adapted for this pur-

<sup>1</sup> Koch's announcement as communicated by special cable from Berlin.

pose. In such an animal the small indentation assumes the same sticky covering at the beginning, but no nodule forms. On the contrary, on the day following, or the second day after the inoculation, the place where the lymph is injected shows a strange change. It becomes hard and assumes a darker coloring, which is not confined to the inoculation spot, but spreads to the neighboring parts until it attains a diameter of from one-half to one centimetre.

In a few days it becomes more and more manifest that the skin thus changed is necrotic, finally falling off, leaving a flat ulceration which usually heals rapidly and permanently without any involvement of the adjacent lymphatic glands. Thus the injected tubercle bacilli affect the skin of a healthy guinea-pig quite differently from one affected with tuberculosis. This effect is not exclusively produced with living tubercle bacilli, but is also observed with the dead bacilli, the result being the same whether, as I discovered by experiments at the outset, the bacilli are killed by a somewhat prolonged application of a low temperature, or boiling heat or by means of certain chemicals. This peculiar fact I followed up in all directions, and this further result was obtained—pure cultivations of tubercle bacilli after being killed and diluted with water, might be injected in great quantities under healthy guinea-pigs' skin without anything occurring beyond local suppuration. Such injections belong to the simplest and surest means of producing suppuration free from living bacteria.

Tuberculous guinea-pigs, on the other hand, are killed by the injection of very small quantities of such diluted cultivations. In fact, within six to forty-eight hours, according to the strength of the dose, an injection which is not sufficient to produce the death of the animal, may cause extended necrosis to the skin in the vicinity of the place of injection. If the dilution is still farther diluted until it is scarcely visibly clouded, the animals injected remain alive, and a noticeable improvement in their condition soon supervenes. If the injections are continued at intervals of from one to two days, the ulcerating injection wound becomes smaller and finally scars over, which otherwise it never does; the size of the swollen lymphatic glands is reduced, the body becomes better nourished, and the morbid process ceases, unless it has gone too far, in which case the animal perishes from exhaustion. By this means the basis of a curative process against tuberculosis was established.

Against the practical application of such dilutions of dead tubercle bacilli there presented itself the fact that the tubercle bacilli are not absorbed at the inoculation points, nor do they disappear in any other way, but for a long time remain unchanged, and engender greater or smaller suppurative foci. Anything, therefore, intended to exercise a healing effect on the tuberculous process must be a soluble substance, which would be liberated to a certain extent by the fluids of the body floating around the tubercle bacilli, and be transferred in a fairly rapid manner to the fluids of the body; while the substance producing suppuration apparently remains behind in the tubercle bacilli, or dissolves, but very slowly. The only important point was, therefore, to induce outside the body the process going on inside, if possible, and to extract from the tubercle bacilli the curative substance alone. This demanded time and toil, until I finally succeeded, with the aid of a forty to fifty per cent. solution of glyce-

rine, in obtaining an effective substance from the bacilli. With the fluid so obtained I made further experiments on animals, and finally on human beings. These fluids were given to other physicians to enable them to repeat the experiments.

The remedy which is used in the new treatment consists of a glycerine extract, derived from the pure cultivation of tubercle bacilli. Into the simple extract there naturally passes from the tubercle bacilli, besides the effective substance, all the other matter soluble in a fifty per cent. glycerine solution.

Consequently it contains a certain quantity of mineral salts, coloring substances, and other unknown extractive matters. Some of these substances can be removed from it tolerably easily. The effective substance is insoluble in absolute alcohol. It can be precipitated by it, though not, indeed, in a pure condition, but still combined with the other extractive matters. The coloring matter may also be removed, rendering it possible to obtain from the extract a colorless, dry substance, containing the effective principle in a much more concentrated form than the original glycerine solution. For application in practice this purification of the glycerine extract offers no advantage, because the substances so eliminated are unessential for the human organism. The process of purification would make the cost of the remedy unnecessarily high.

Regarding the constitution of the more effective substance, only surmises may for the present be expressed. It appears to me to be a derivative of albuminous bodies, having a close affinity to them. It does not belong to the group of so-called toxalbumins, because it bears high temperatures, and in the dialyzer goes easily and quickly through the membrane. The proportion of the substance in the extract to all appearance is very small. It is estimated at fractions of one per cent., and if this is correct we should have to do with a matter whose effects upon organisms attacked with tuberculosis goes far beyond what is known to us of the strongest drugs.

Regarding the manner in which the specific action of the remedy on tuberculous tissue is to be represented, various hypotheses may naturally be put forward. Without wishing to affirm that my view affords the best explanation, I represent the process myself in the following manner: The tubercle bacilli produced when growing in living tissues, as in artificial cultivations, contain certain substances which variously and notably unfavorably influence living elements in their vicinity. Among these is a substance which in a certain degree of concentration kills or so alters living protoplasm that it passes into a condition that Weigert describes as coagulation necrosis. In tissue thus become necrotic the bacillus finds such unfavorable conditions of nourishment that it can grow no more and sometimes dies.

This explains the remarkable phenomenon that in organs newly attacked with tuberculosis, for instance in guinea-pigs' spleen and liver, which then are covered with gray nodules, numbers of bacilli are found, whereas they are rare or wholly absent when the enormously enlarged spleen consists almost entirely of whitish substance in a condition of coagulation necrosis, such as is often found in cases of natural death in tuberculous guinea-pigs. The single bacillus cannot, therefore, induce necrosis at a great distance, for as soon as necrosis attains a certain extension the

growth of the bacillus subsides, and therewith the production of the necrotizing substance. A kind of reciprocal compensation thus occurs, causing the vegetation of isolated bacilli to remain so extraordinarily restricted, as, for instance, in lupus and scrofulous glands.

In such cases the necrosis generally extends only to a part of the cells, which then, with further growth, assumes the peculiar form of the giant cell. Thus the explanation Weigert gives of the production of giant cells follows from this interpretation.

If now the amount of necrotizing substance in the tissue were artificially increased in the vicinity of the bacillus the necrosis would spread a greater distance. The conditions of nourishment for the bacillus would thereby become more unfavorable than usual.

In the first place the tissue which had become necrotic over a larger extent would decay and detach itself, and where such were possible would carry off the inclosed bacilli and eject them outwardly, so far disturbing their vegetation that they would much more speedily be killed than under ordinary circumstances.

It is just in such changes that the effect of the remedy appears to consist. It contains a certain quantity of necrotizing substance, a correspondingly large dose of which injures certain tissue elements even in a healthy person, and perhaps, also, the white blood corpuscles or adjacent cells, thereby producing fever and a complication of symptoms; whereas with tuberculous patients a much smaller quantity suffices to induce at certain places—namely, where tubercle bacilli are vegetating and have already impregnated the adjacent region with the same necrotizing matter—more or less extensive necrosis of the cells, with the phenomena in the whole organism which result from and are connected with it.

For the present, at least, it is impossible to explain the specific influence which the remedy, in accurately defined doses, exercises upon tuberculous tissue, or the possibility of increasing the doses with such remarkable rapidity, or the remedial effects which have unquestionably been produced under not too favorable circumstances.

#### VIRCHOW ON THE EFFECTS OF KOCH'S METHOD.<sup>1</sup>

At the Berlin Medical Society on January 7th, Professor Virchow exhibited specimens from twenty-one patients treated by Koch's method who died before January 1st. Since then six or seven more necropsies had been made by him and specimens from these were also shown. Of the former series, sixteen were cases of phthisis.

Professor Virchow illustrated the irritating effects of the fluid by the specimen of a brain removed from a child with tuberculous arachnitis, who died after four injections of the lymph amounting in all to two milligrammes. There was intense hyperemia of the brain and pia mater such as Professor Virchow had never before seen. The vessels of the pia were extremely engorged and the brain-substance internally was of a dusky-red tint. The speaker could not see any signs of retrogressive metamorphosis of the tubercles. Acute hyperemia and swelling were also seen in the internal organs of other cases. The walls of old cavities in the lungs showed unusual

redness of the granulations and recent hæmorrhages. In one case hæmoptysis from an old cavity was the immediate cause of death.

Virchow says there can be no doubt that in internal organs acute inflammation and active proliferation are set up by injections of the fluid. These conditions are seen particularly in the edges of tuberculous ulcers and in neighboring lymphatic glands, especially the bronchial and mesenteric glands. These glands swell to quite an unusual extent and rapid proliferation of the cells in their interior takes place. The colorless elements of the blood are increased and a condition of leucocytosis is established. In the larynx, even when the surfaces of the ulcers become clean, swelling of the adjoining parts may be dangerously great. He showed a recent specimen in which erysipelatos-like œdema of the glottis and a retro-pharyngeal phlegmon had been produced. The changes in the lungs consisted in caseous hepatization, of which an extreme example was shown.

This condition existed in five out of the sixteen cases of phthisis, associated with a special form of pneumonia, resembling the catarrhal type, but differing therefrom in the character of the secretion. The lungs in some places presented foci of softening, and even cavities, the result of acute inflammation caused by the injections of the lymph.

The most important effect observed, however, was an eruption of fresh crops of tubercles after the injections. This occurs especially in the pleura, pericardium, and peritoneum, and Virchow says that in the case of these serous membranes the statement that the substance of the tubercle is destroyed by the remedy is not confirmed by his examinations; he adds that if the effect of the remedy is to cause breaking down, the result would be to release the bacilli and give rise to new foci of tuberculous disease in other parts of the body by infection with the products of disintegration. Virchow, therefore, urges the greatest caution in the use of the remedy. While admitting that in many cases the lymph does produce the effects claimed for it, he points out that this result is not constant, and he cites cases in which large masses of tubercle were entirely unaffected by injections. He also showed specimens in which perforation of the intestines had been caused by the treatment, and one case of tuberculosis of the larynx in which fresh and extremely intense eruptions of tubercles had taken place throughout the whole extent of the larynx and trachea.

On January 14th, before the Berlin Medical Association, Professor Virchow resumed his lecture on the subject of cases which have resulted fatally after the inoculations of the Koch remedy. He said that he was not prejudiced against the remedy; he simply wished to give warning regarding its too general application. In the discussion which followed, Professors Frankel and Baginsky spoke in support of Professor Virchow's contention that tubercular disease was sometimes transferred to sound organs by inoculation. Numerous patients in Vienna, after reading the views expressed by Professor Virchow, declined to submit to further treatment by the Koch method.

*Wife of Physician.*—"I see here in the *Constitution* a reference to 'Woman's Serious Side.' Which side is it?—right or left?"

*Husband.*—"From my medical journals, I should think it was her inside."

<sup>1</sup> Medical News, January 17, 1891.

# KOCH'S NEW TREATMENT AT THE JOHNS HOPKINS HOSPITAL.

At the Medical Society meeting of the Johns Hopkins Hospital on Monday, January 5th, Dr. ABBOTT who had been to Berlin to study the Koch treatment, gave an account of his experience at the hospital clinics.

At the Children's Hospital he saw cases of pleuritic and intestinal tuberculosis, which were treated with increasing quantities of the fluid. The expected reactions always followed, though an absolute cure was rare. Koch says that it takes from four to six weeks to effect a cure in a very favorable case of recent origin. In several cases tubercles seemed to disappear for a few days, only to return as they often do under other forms of treatment.

In tubercular pleurisy the usual reactions took place, frequently followed by secondary fever, and every case gave the typical reaction under two milligrammes of the injected fluid.

The physicians everywhere are becoming more conservative as to their hopes of permanent cure; and it is especially in intestinal tuberculosis that the results are poor and discouraging.

The surgical cases were much more favorably influenced. Lupus was frequently cured within two months.

Joint cases of tuberculous origin gave the characteristic results, and the injection was freely used as a means of diagnosis. One case of ankle-joint disease was treated by the fluid, it gave the proper reaction several times, but the condition of the joint did not improve until after opening the cavity, necrotic tissue was removed, in which tubercle bacilli were found; these were also found in the walls of the joint, as if they had been thrown off in the efforts of reparation. In the adjoining bed was a patient suffering from tuberculosis of the knee-joint. The joint was opened after repeated injection and here healthy tissue was found with cicatricies of tubercular tissue.

In any scrofulous or cicatricial tissue there is marked reaction to the fluid. One boy who had renal tuberculosis was injected several times; following each injection the cicatricial tissue of an old wound in his neck, two and one-half inches long, grew tumid and painful, and finally broke down.

Wherever in joint diseases the cavity was opened soon after the injection, the necrosed tissue which had been thrown off by the fluid escaped, and the healing was much more speedy and complete.

In most cases the reactionary fever appeared in from two to three hours; climax was reached in about twenty hours; in some patients, however, one or two days elapsed between the treatment and the customary symptoms. With the fever there was always an increase in the physical signs of the disease, or if no disease was present, there would be found a softening in the apex of one lung following injection, although in these cases it was rare to have much expectoration.

Among the results of the treatment most frequently noticed were haemorrhage, icterus, hæmatogenous, temporary albuminuria, and, in children, diarrhoea.

Dr. MORRISON presented a case of lupus, which had been under his care for several years. None of the carbolic or other modes of treatment had resulted in any marked benefit. When the woman was admitted to the hospital December 16th, she had sixteen furuncles, and eighteen crusty ones; there was

extensive ulceration on the inner side of her nose and a surface as large as the palm of the hand was involved. On December 16th she was injected with one milligramme of Koch's fluid. This was followed by the usual fever, swelling of the sores, itching of the nose, etc., but the induration was much improved—desquamation followed each treatment. When shown at the clinic she had been given four injections, the ulceration was healed, the furuncles and crusts had mostly disappeared, and the redness was not more than one half as vivid or diffused.

Dr. HOWARD KELLY reported several cases of tubercular peritonitis and salpingitis, which he had treated with Koch's fluid.

OPINIONS ON THE RECIPE FOR MAKING THE LYMPH.—The value of the special cablegrams which were received last week, disclosing Koch's secret, seem to be very differently estimated, as the following opinions indicate:

(1) "We should say that there might be some risk of error should one attempt to manufacture the lymph merely by the light of such directions as have come to us by cable. Although we are of the Indo-Germanic race, the language of a thoroughbred Teuton often seems to an Anglo-Saxon to lack precision and perspicuity. So when Dr. Koch tells us that, if a healthy guinea-pig be inoculated with the pure cultivation of German kultur of tubercular bacilli, the animal dies, we are not disposed to doubt the proposition. But the mere fact that guinea-pigs die under such treatment makes it all the more necessary that we should exactly inform ourselves, on the spot, precisely what is this German kultur of tubercular bacilli. The submarine cable is excellent in the way of giving current news; but a great discovery should be explained and disseminated at shorter range."

(2) "From this prescription I can now make lymph. It is only necessary to inoculate a sterilized glass tube partly filled with a decomposition, which generally consists of beef broth and gelatine. This decomposition is sterilized by being heated, then cooled. Then a pure germ of the disease is placed in the tube, which then is put in an oven heated to a temperature of 98 degrees. This is left in this incubator three or four weeks, during which time the fungus grows, and then we have the lymph."

(3) "One must be inoculated with wisdom and understanding to know what the Koch lymph is, now that it has been explained."

REASON ENOUGH.—"They say Dr. Koch's lymph is dutiable under the McKinley bill. Now why should it be?"

"It interferes with home consumption."

A COFFEE-HOUSE, with pretty waitresses, has opened in Berlin, bearing over its portals a sign consisting of Koch's portrait, with the inscription, "The Jolly Bacillus."

THE BOSTON

**Medical and Surgical Journal.**

THURSDAY, JANUARY 22, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.***SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.**All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.**Remittances should be made by money-order, draft or registered letter, payable to*DAMRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

## THE NATURE OF KOCH'S PARATALOID.

We publish in another column, for the sake of convenient future reference, the text received by cable of Professor Koch's last communication concerning his parataloid, or, as it is known in the vernacular both of the profession and of the laity, his "lymph." A cable despatch, however full, is not an altogether satisfactory medium through which to make the acquaintance of the method of evolution of a process so complicated and delicate as this discovery, or of the composition of a fluid so powerful and so unusual as that which Koch has furnished, after four or five years of minute laboratory experiment, to the medical world.

In proof of this it is only necessary to regard some of the evident errors in this "special cable," and to compare some of the opinions expressed as to the practical value of the information conveyed.

One of our very much esteemed "Knickerbocker" medical contemporaries expresses itself thus editorially:

"We see no reason why it should not now be prepared in any well-equipped bacteriological laboratory, and thus the restriction heretofore put upon its general employment be ended. In the absence of a more detailed account of its preparation than Professor Koch gives, it may, we think, be assumed that any person who would consider himself conversant enough with bacteriological methods to attempt the work of producing such a liquid would not, even without a hint as to the steps in the process necessary, have been in the least likely to produce an agent more dangerous than the Koch liquid itself."

The other contemporary, also esteemed, on the other hand thinks editorially thus:

"The publication of Professor Koch regarding the composition of the lymph, considering the great expectations which have been aroused concerning it, is rather disappointing than otherwise. With few exceptions his statements have been already anticipated, and in many other respects no new facts have been added to those that have been accumulating during the past few months.

"Aside from the mention of the ingredients contained

in the fluid we are in little if any better condition as to the possibility of its production in our own laboratories than we were before. Still, the information, as far as it is given, will add much interest to the study of the results of "lymph" treatment in their relations to the supposed causes of their production. In other words, we are so much the better enabled to think for ourselves, and so much the more encouraged to work in accumulating data by which the new theory must stand or fall. We are making enough progress in the latter direction to take courage accordingly, and hope for the best in the direction of eventually settling many of the mooted points of a startling revolutionary doctrine."

The enterprising metropolitan press credits the enterprising head of the Marine Hospital Service with the intention of immediately putting in order the laboratory of the Marine Hospital at New York, the largest in the United States (a truly metropolitan laboratory), with a view to the manufacture of "lymph," as soon as some one now in Berlin returns; and if Congress—as the Marine Hospital Service anticipates—appropriates \$10,000 in the Sundry Civil Bill at this session, another laboratory (not factory), will be erected in Washington for the manufacture!

The truth is we had much better make up our minds to go slowly in this matter, and there will be less to take back later. The Trans-Atlantic cable is a useful disseminator of news, and "hustling" is a remunerative quality at certain times and places; but it was not by electrically conducted studies that Koch devised his methods, nor by "hustling" that he reached the results he now offers us. Why should we not imitate him where, perhaps, we can, to wit, in patience and self-possession? When the popular furor has subsided, and turned to some other novelty, the real work will begin, and a year hence there may be sufficient data upon which to reach some definite conclusions, as to the action and capabilities of this particular substance, and we may hope to gain some clearer conception of the possible extension of the scientific principles involved to other diseases.

We hope that a large number of "equally good lymphs" will not be immediately thrown on the market; and that no "lymph" will be "manufactured" from a "pure cultivation of German kultur of tubercular bacilli." We believe that experienced bacteriologists will not yet consider themselves justified in undertaking the production of parataloid, however large their laboratories may be; but that others may rush in where they, as yet, abstain from treading, we are not prepared to doubt. Although not throwing open the immediate production of "lymph" to every one having a bacteriological laboratory, the communication of Dr. Koch is a very timely and acceptable one, and places the profession and the public in a more just and legitimate relation to him and to the subject which both he and they have at heart. He is probably as well satisfied at finding himself in a position to make the communication as we are glad that he has made it.

## NEW RESEARCHES ON VARIOLA VACCINE.

SOME interesting researches have been lately undertaken by M. Haccius, Director of the Vaccinal Institute of Lancy (Geneva), and Eternod, Professor of Histology in the Geneva School, which go to confirm those published last year by Fischer in the *München Med. Wochenschrift*, and make the identity of Variola and Vaccine more than probable. The conclusion at which Thiele, Cedy, Voigt and Depaul arrived many years ago, namely, that cow-pox is a modified form of small-pox, *attenuated* by its passage through the organism of an animal, was disputed by the Lyonsese Commission (Chauveau, Layet, Berthet and others), who adduced seemingly unimpeachable experiments of their own contradictory of that proposition, and the profession, since that time, basing itself on those experimental results, has considered the non-transmissibility of small-pox to domestic animals, and the duality of variola and vaccine as proven.

Haccius and his colleague, following the operative method of Fischer, claim that they have succeeded in imparting small-pox to animals, and in transmitting it through several generations, the disease eventually manifesting itself in a mild form indistinguishable from true cow-pox, and, like the latter, conferring immunity from variola.

Believing that the method of inoculation by pricks and incisions practised by the Lyons Commission was insufficient, and that experiments based upon this method were inconclusive, these later experimenters have resorted to a procedure which they call *vaccination in surface*, or *vaccination by denudation*. Fischer's method was rather one of extensive scarification (*Imp-flache*). Haccius and Eternod denude the skin of the animal over an extent of several square centimetres by means of a thin glass-scraper. A little hæmorrhage follows, then some oozing of serum, which they carefully wipe off by means of a sterilized cloth. Then they rub the denuded surface with a spatula charged with the small-pox virus. They assert that by this procedure they have never failed to obtain success, while the method of pricks and incisions is very apt to fail.

In their experiments they find that in the first generation there is produced a local eruption, accompanied by "spontaneous" pustules, always in small number, the entire eruption having an aspect but little typical, somewhat "abortive," and this is, they think, what led the Lyons Commission into error. If from the product of these papules another series of inoculations be practised, and a third from the results of the second, the scene soon changes; at the end of the second or third generation the pustulation tends to become typical by taking on more and more the mode of evolution and the characters of the vaccinal eruption. After the third generation, "an expert would assuredly have difficulty in distinguishing the pustules in these animals from those that are obtained in the vaccinated institutes by the inoculation, in the first generation, of spontaneous cow-pox."

In each animal the counter-proof was carefully made with animal vaccine; all the animals that had been before inoculated with small-pox virus were invariably refractory to vaccine.

In one of these series of experiments Haccius and his colleague succeeded in transmitting the small-pox virus from heifer to heifer to the fourteenth generation, and side by side with a set of similar observations where vaccine virus was used. They have at the present time a series under observation where the heifers were inoculated with virus from a case of confluent small-pox; lymph from "the fourth generation" has given the results of ordinary vaccine when used for purposes of vaccination.

The conclusions formulated by these experimenters are as follows:

(1) Variola is inoculable *with certainty* on the bovine species when the operative method is such as it should be, and the virus is collected at the opportune moment.

(2) The inoculation of small-pox to the heifer constitutes a precious source for new re-enforcements of animal vaccine. This may be of great practical benefit, not only to the vaccinal institutes of Europe, but also to tropical countries, where small-pox is endemic, and where the generations of vaccine tend rapidly to deteriorate.

(3) Small-pox inoculated in the heifer becomes transformed into vaccine in the course of several generations by transmission through this animal. *Duality is thus disproved.*

(4) Our practical conclusions confirm the views enunciated by Depaul in 1863 to the Academy of Medicine of Paris.

## MEDICAL NOTES.

## GERMAN CONGRESS FOR INTERNAL MEDICINE.—

The Tenth Congress of Internal Medicine will be held at Wiesbaden from April 6th to 9th, 1891, under the presidency of Professor Leyden of Berlin.

SMALL-POX.—On account of the epidemic of small-pox in Mexico, the Governor of Texas has declared the State quarantined against all cities and towns with cases of small-pox. El Paso is the only city on the Rio Grande not included in the governor's quarantine proclamation.

SACCHARIN IN RUSSIA.—Following the example of France and Italy, the Russian Medical Council has prohibited the use of saccharin as an article of food. Henceforward the substance will be dispensed by apothecaries and druggists only on medical prescription.

COLD WEATHER IN EUROPE.—The intense and prolonged cold weather from which the whole of Europe, and even the northern coast of Africa is suffering, is reported to have increased the death-rate in many places, even in the more southern countries. The people, not being accustomed to such cold, have suffered from exposure to an extent which it is diffi-

cult for those, who are used to severe winters, to understand.

**A MEDICAL PRACTITIONERS' PROTECTIVE ALLIANCE** has been formed in Baltimore, with the laudable objects of "maintaining organized co-operation among practising physicians, protecting themselves against the dispensary abuse and inferior medical schools, and devising means of improving their financial position in every honorable way." This seems to be a step towards that combination among doctors for the redress of professional grievances, and the promotion of their own interests, which is a necessary condition for the reform of the present unsatisfactory state of the medical commonwealth.

An ordinance has been passed in Indiana which compels all railroad companies to put storm doors on all railroad coaches and street cars for the carriage of passengers, to keep the temperature from sixty-eight to seventy in the cars, and to furnish spittoons partly filled with bichloride of mercury, for the use of persons suffering from chronic cough and expectoration.

#### NEW ENGLAND.

**RESIDENT PHYSICIAN AT LONG ISLAND.**—Dr. Daniel S. Harkins, Assistant Port Physician, has been appointed Resident Physician at Long and Rainsford Islands, Boston Harbor. The last holder of the place was Dr. J. I. McLaughlin, who resigned some months ago. Dr. R. E. Darrah will succeed Dr. Harkins as assistant port physician.

**THE DRINKING-WATER SUPPLY OF LOWELL.**—It appears that the drinking water of Lowell, where there has lately been an epidemic of typhoid fever, referred to in our last issue, is taken from no less than five different sources: (1) The locks and canals; (2) the canal; (3) the Merrimack River; (4) wells; (5) springs. The water of the locks and canals is open to grave suspicion, and into the canal water, which is undoubtedly used in the mills, the sewage of the hospital is discharged.

**THE TEWKSBURY ALMSHOUSE.**—In his annual report the superintendent of the Massachusetts State Almshouse at Tewksbury reports that the hospitals have received during the year 1,969 patients. There were 198 deaths and 103 confinements; of the latter 79 were illegitimate. A new ward has been opened, increasing the number of beds to 140 in the male hospital. The improvements in the hospitals long contemplated, have been completed. The superintendent is under the impression that syphilis is the cause of pauperism in a large proportion of cases, and urges that such legislation be asked for as will enable patients to be held until the infectious stages be passed. The records show that fully fifty per cent. of men and women admitted have had the disease in some form.

**TUBERCULOSIS IN MILK.**—A petition has been presented to the Legislature from a committee of the board of trustees of the Massachusetts Society for Promoting Agriculture, with reports showing that tuberculosis exists extensively in this State, as well as

in others, among persons and cattle; that the milk from cows diseased with tuberculosis in the udder and elsewhere can communicate this disease to man, and that the number of cows which exist in Massachusetts diseased in this manner is uncertain. The Society presents these reports and statements, and petitions that a hearing upon this matter may be given them in order that facts and information may then be more fully presented, and that suitable means and methods may be considered for overcoming the danger.

#### NEW YORK.

**NEW YORK ACADEMY OF MEDICINE.**—At a meeting of the New York Academy of Medicine held January 15th, Dr. Alfred L. Loomis was re-elected President, Dr. Edward L. Keyes was elected Vice-President; Dr. Frederick A. Castle, Trustee; and Dr. Wm. F. Cushman, Treasurer for the Trustees. There was a discussion on Chronic Cervical Adenitis in Children, under the charge of the Section on Pediatrics, in which the subject of the etiology, symptomatology and diagnosis was introduced by Dr. A. Jacobi; the medical treatment by Dr. Wm. H. Thomson, and the surgical treatment by Dr. Frank Hartley.

**BELLEVUE HOSPITAL TRAINING SCHOOL FOR NURSES.**—The graduating exercises of the Bellevue Hospital Training School for Nurses were held January 13th. The Hon. Wm. E. Dodge presided, and Dr. Joseph D. Bryant delivered the address to the graduating class, which numbered 20. One of the class is to go to Asia Minor to take charge of a school for nurses that is to be established near Damascus.

On January 16th the returns from the Hospital Saturday and Sunday collection had amounted to \$46,205.

### Miscellany.

#### POISON-PROOF ANIMALS.

**RABBITS**<sup>1</sup> possess an unaccountable immunity against belladonna leaves. They may be fed on them for weeks without observing the least toxic symptoms. The meat of such animals, however, proves poisonous to any one who eats it, producing the same symptoms as the plant. Pigeons and various other herbivora are also to some degree safe from the effects of this poison, while to warm-blooded carnivora it is very poisonous. The meat of goats which had fed on hemlock has sometimes occasioned poisonous effects. Chickens are nearly hardy against nuxvomica and the extremely dangerous alkaloid, strychnine, contained in it, while in the smallest amount it is a fatal poison to rodents. More remarkable yet in this respect is the immunity of *Cholepus Hoffmanni*, a kind of sloth, living on the island of Ceylon, which, when given ten grains of strychnine, is not much affected. Pigeons are possessed of high immunity from morphine, as well as from belladonna. Of the former, eight grains have been required to kill a pigeon. Cats are extremely sensitive to digitalis, which on the contrary may be given to rabbits and various birds in pretty large doses.

<sup>1</sup> W. Bernhardt, in the Popular Science Monthly for January.

## PROGRESSIVE PARALYSIS.

PICK,<sup>1</sup> in an account of the histology of progressive paralysis, finds in the brain, which has been hardened in alcohol, on microscopic examination of the cerebral cortex, a number of elongated dark bodies, which take the stain well, and are, for the most part, so placed that their long axis is at right angles to the cerebral cortex. These, at first sight, are very liable to be mistaken for the nuclei of the vessels, but further careful consideration shows that their direction is too constant, their size too great, and their staining too deep. Higher magnifying power shows that they are really swellings on the axis cylinders of the nerve cells; they are for the most part placed on the nerve fibre at a point near the cell. These swellings discovered by Pick accord with the changes which other authors have described as likely to be met with in the brain of persons dying of progressive paralysis. They are probably to be regarded as the first stage of sclerosis.

## TO BE REMEMBERED.

AMONG a number of facts which Dr. H. M. Whelpy<sup>2</sup> has compiled and recommends all druggists to remember, may be found some useful to physicians also.

Cocaine and borax form an insoluble borate of cocaine, while boric acid and cocaine do not. Cherry laurel water and morphine salts are liable to form the poisonous cyanide of morphine. Rose water made with carbonate of magnesium and used to make eye-water by dissolving zinc or lead salts, will form an irritating precipitate. Carbolic acid is combustible. Iodine and the iodides precipitate the alkaloids. Etherial solutions of iodiform are not permanent. Granulated gum arabic dissolves more readily than the powdered. Powdered camphor can be kept in the pulverent form by the addition of one-half per cent. of oil of vaselin. Sugar added to ordinary ink forms a good copying ink. Quinine will preserve mucilage, paste, etc. Many celluloid articles can be mended by covering the edge with glacial acetic acid and pressing them firmly together until dry. Official chemicals are not always "C. P." The term "U. S. P." and "C. P." are not synonymous. The metric system has been adopted for the seventh decennial revision of the U. S. P., and it is time to learn the principles of the system.

## TO CONTROL HÆMORRHAGE AFTER LAPAROTOMY.

A NEW method of dealing with severe hæmorrhage from the peritoneal cavity after the removal of large tumors, etc., is described by Walcher.<sup>3</sup> Drainage by tubes and by gauze has been tried; Dr. Walcher combines both methods. He has contrived very wide glass tube, with a channel of from nine-tenths of an inch to one inch and a tenth in diameter and from six to nine inches long. The tube is passed into the deepest part of the bleeding cavity or down to the bottom of Douglas's pouch. Then a strip of iodotannic gauze about two inches broad is passed carefully down the tube till

a good large bunch of the gauze presses against the bleeding part. In one case Dr. Walcher thus inserted a piece larger than a man's fist. The free end of the strip of gauze is left in the tube, which is closed with a plug of wool. An assistant presses the tube against the bleeding spot whilst the operator closes the abdominal wound. The tube is placed in the lower third of the wound. The gauze plug may usually be removed on the second day. By aid of a head mirror, the surface whence the bleeding proceeded may be examined. The wound is closed by sutures passed through its entire thickness, including the peritoneum, when the tube is removed. Should hæmorrhage recur when the first gauze plug is withdrawn, a second plug must be passed down the tube. The great objection to this plugging is its liability to cause retention of flatus. Two cases out of seven in Dr. Walcher's experience suffered in this manner for about two days. The abdominal wound in all the cases healed well, the portion at the site of the tube closing as firmly as the remainder.

## NOTHING NEW UNDER THE SUN.

It is curious to find that something like the present-day theories of a struggle between the microbes and leucocytes must have been in vogue more than a century ago, otherwise this bit of satirical burlesque<sup>4</sup> could scarcely have been written and played.

"Dramatis Personæ: The Devil as Hellebore, president of the college; Dr. Last, a new licentiate; other doctors and pupils.

"*Hel.*—Proceed we now to the lecture! Brethren and students, I am going to open to you some notable discoveries that I have made respecting the source or primary cause of all distempers incidental to the human machine. And these, brethren, I attribute to certain animalcules of piscatory entities, that insinuate themselves through the pores into the blood, and in that fluid sport, toss, and tumble about, like mackerel or cod-fish in the great deep. And to convince you that this is not a mere *gratis dictum*, an hypothesis only, I will give you demonstrative proof. Bring hither the microscope! Dr. Last, regard this receiver. Take a peep. Those two yellow drops there were drawn from a subject afflicted with the jaundice. Well, what d'y'e see?

"*Last.*—Some little creatures, like yellow flies, that are hopping and skipping about.

"*Hel.*—Right. Those yellow flies give the tinge to the skin, and undoubtedly cause the disease. And now for the cure! I administer to every patient the two-and-fiftieth part of a scruple of the ovaria or eggs of the spider; these are thrown by the digestive powers into the secretory, there separated from the alimentary, and then precipitated into the circulatory, where finding a proper nidus or nest, they quit their torpid state, and vivify, and upon vivification, discerning the flies, their natural food, they immediately fall foul of them, extirpate the race out of the blood, and restore the patient to health.

"*Last.*—And what becomes of the spiders?

"*Hel.*—Oh, they die, you know, for want of nutrition. Then I send the patient down to Brighthelmston, and a couple of dips in the salt water washes the cobwebs entirely out of the blood."

## PRESCRIPTIONS.

**DIURETIN.**—A good formula for the prescription of diuretin, as given by Schroeder,<sup>1</sup> is:

R Diuretin . . . . . 3 ij.  
Syrup. simp. . . . . ss.  
Aque meuth. pip. . . . . 3 iv.  
Aque destil. . . . . ad 3 viij. M.  
Sig. A teaspoonful every one or two hours.

**A LOCAL ANÆSTHETIC.**—For minor operations Dobisch<sup>2</sup> sprays this mixture on the skin for about a minute:

R Menthol . . . . . 1 part.  
Chloroform . . . . . 10 parts.  
Ether . . . . . 15 parts. M.

**DESQUAMATION AFTER SCARLET FEVER.**—Starr<sup>3</sup> advises the following: Anoint the entire surface of the body, including the scalp, daily, with an ointment of

R Acidi carbolici . . . . . gr. xx.  
Thymol. . . . . gr. x.  
Vaselin vel ung. simp. . . . . 3 j. M.

Then put in a warm bath for five minutes, protect from cold, and put to bed, wiping the body dry beneath the bed-clothes.

**GLYCERIN SUPPOSITORIES.**—Ballard<sup>4</sup> gives the following formula, stating that the suppositories are not brittle:

R Lanolin. . . . . 55 gr. xxx.  
Glycerin . . . . . 55 gr. x.  
Cacao butter. . . . . 55 gr. x.  
White wax . . . . . 55 gr. x.  
For one suppository. M.

The lanolin is first melted with the wax and the cacao butter. Then the glycerin is added, and the mass is poured into molds. The molds should be placed in a mixture of ice and salt to prevent a separation of the glycerin.

## Correspondence.

HUGH OWEN THOMAS.

Boston, January 16, 1891.

MR. EDITOR:—In the obituary notice of Mr. Hugh Owen Thomas in your last issue, mention was made of the fact that he was exceedingly kind to Americans who called upon him, and none left him without being impressed with the originality, honesty and earnestness of the man. As one of those Americans who have enjoyed his courtesy and kindness, may I add a few words to the notice you have already published in your journal?

Mr. Thomas was not only an honest, original and earnest man; he was an unusual man, and one who attained to remarkable success. He was essentially in type a Welshman, and differed to a marked degree from the average Englishman in manners and methods. But, if achievements are the measure of men, Mr. Thomas's name would be placed high among the list of British surgeons; for although his work has been turned largely in a special direction, yet to those who are acquainted with his results, nothing but a tribute of praise can be said of what he accomplished. It is given to few men to attain to the position in the general popular mind that was held by Mr. Thomas among the people of Liverpool. This indicated, not only an unusual readiness in dealing with people in a high degree, but, those qualities of the practitioner which, in themselves, often bring success. To this, Mr. Thomas added force, originality and directness of thinking, persistency and determination. He accepted nothing on tradition, "Nullius

in verbo magistri," was a motto he lived up to: he thought everything out for himself, and thought in a way that indicated intelligence and unusual alertness of mind. His book on "Diseases of Hip, Knee and Ankle-Joint" is full of originality and demonstrated clearly that whatever Mr. Thomas wrote should be fully considered, and most of it accepted. The boldness of his methods was often only equalled by the ingenuity of his mechanical appliances.

As a writer in medical matters he was direct, original, and forcible. His suggestions as to the treatment of fractures of the neck of the femur, of ununited fractures, of treatment of fractures of the patella, are both interesting, valuable and important. Among many devices which he used, the well-known Thomas splint for the treatment of the knee and ankle is of great value; the collar for treatment of caries of the spine in the cervical region is one that places rational treatment in the hands of every practitioner. Of his many inventions may be mentioned the well-known splint for the treatment of hip, the shoe for flat-foot, the very ingenious shoe for the treatment of inflammation of the toe-joint, the elbow splint, the appliance for the correction of club-foot, the clamp for fractures of the lower jaw.

Any one who has come in personal contact with him will also bear testimony to the breadth of his range of thinking and reading, his active mind in matters of national affairs, the boldness and sincerity of his religious views, and his intellectual quickness and frankness. It was always a stimulant to meet him, and his memory will always be valued by those who knew him.

Very truly yours,  
E. H. BRADFORD, M.D.

## RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JANUARY 10, 1891.

Cities.	Estimated population for 1890.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from					
				Infectious diseases.	Acute lung diseases.	Typhoid fever.	Diphtheria and croup.	Scarlet fever.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 10, 1891, TO JANUARY 16, 1891.

## PROPOSITIONS

To be assistant surgeon with the rank of captain, after five years' service, in accordance with the act of June 23, 1874, Assistant Surgeon HENRY S. T. HARRIS, January 5, 1890, Assistant Surgeon LEONARD WOOD, January 5, 1891. A. G. O., Washington, D. C., January 12, 1891.

By direction of the Secretary of War, First Lieutenant HENRY D. SAYRE, assistant surgeon, is relieved from duty at Fort Reno, Oklahoma Territory, and will report in person to the commanding officer, Camp Guthrie, Oklahoma Territory, for duty at that station, relieving Captain JOHN L. PHILLIPS, assistant surgeon. Captain Phillips, on being so relieved, will report in person to the commanding officer, Fort Reno, Oklahoma Territory, for duty at that station. S. O. 11, Par. 16, A. G. O., Washington, D. C., January 12, 1891.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS  
OF THE U. S. NAVY FOR THE WEEK ENDING JAN-  
UARY 15, 1896.

W. L. Howe, medical doctor, ordered as president of Medical Board, to resign Medical Director J. V. Taylor.

B. C. Dray, medical director, detached from Hospital, Chel-  
sea, and to Medical Board, Washington, D. C.

1. A. E. Vinton, local director, to be placed on the retired list January 1951.

W. H. L. is published as a fund-raising order to the "Newspaper" is published.

REYNARD A. VERNON, peered at assistant surgeon, orders to the State a 'needed, and wait orders.

A. G. CABELL, passed assistant surgeon, detached from "Iron Clads," and to the "Newark."

G. P. LUMSDEN, passed assistant surgeon, ordered to the "Iron Clads," at Richmond, Va.

## SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT. — A regular meeting of the Society will be held on Monday, January 26, 1891, at the Medical Library, 19 Boylston Place, at 8 o'clock P. M.

Papers: Dr. H. Osgood, "The Outcome of Personal Experience in the Application of Hypnotism and Hypnotic Suggestion"; Dr. C. F. Folsom, "A Case of Arsenical Neuritis."  
G. G. SEARS, M.D., *Secretary.*

NORFOLK DISTRICT MEDICAL SOCIETY.—A meeting for Scientific Improvement will be held on Tuesday, January 27, 1891, at 7.45 P. M., at the house of Dr. Bolles, "The Warren," Warren Street corner St. James St., Roxbury.

Communications: (1) "Some Unusual Results from the Use of Sulphuric Ether," W. S. Everett, M.D. The discussion will be opened by Drs. R. H. Fitz and W. P. Bolles. (2) "A Case of Apparent Intestinal Obstruction," A. E. Austin, M.D.

The Committee appointed to consider the propriety of changing the boundary lines between the Norfolk and Suffolk District Societies will give a hearing upon the question at the Boylston Library Rooms, on Thursday, January 24th, at 8 P. M. All Fellows interested are invited to be present.

## OBITUARY. EDWARD C. HARWOOD, M.D.

Dr. Edward C. Hartwood, a prominent practitioner, died, January 15th, in the fifty-second year of his age. He was born in Barrington, Vt., November 28, 1838, and graduated from Bellevue Hospital Medical College in 1860. After pursuing a post-graduate course of study in Europe, he settled in New York, where he has practiced ever since. He was one of the founders of the Society of Medical Jurisprudence and State Medicine, and a number of years ago he was associated with Drs. Wm. A. Hammond and E. C. Spitzka in the movement for reform in the public insane asylums.

DEATHS.

Dr. Alvan Talcott, one of the oldest living graduates of Yale University, died in Guilford, Conn., January 17th. He was eighty-eight years of age. He has been widely known, not only as a practitioner, but also as a learned Greek scholar.

Joseph Parrish, M.D., formerly Superintendent of the Pennsylvania Training School for Feeble-Minded Children, President of the American Association for the Cure of Inebriates, died at Burlington, N. J., January 15th, aged seventy-two.

Professor John Marshall, F.R.S., F.R.C.S., LL.D., M.D., etc., died, January 1st, aged seventy-two.

Edward Bellamy, F.R.C.S., Senior Surgeon to Charing Cross Hospital, London, died, January 4th, aged forty-eight.

## BOOKS AND PAMPHLETS RECEIVED.

The Atmospheric Tractor. By P. McCahey, M.D., of Philadelphia.

Cephalorhynchus Verum Externum. By Howard A. Kelley, M.D. Reprint. 1890.

The Medical Expert. By J. T. Eskridge, M.D., of Denver, Col. Reprint, 1890.

Aerztlicher Almanach. Herausgegeben von Med. Dr. Adolf Köllay. X Jahrgang. Wien: Wilhelm Braumüller & Sohn, 1891

Sixth Biennial Report of the Board of Trustees and Officers  
of the Minnesota Hospitals for Insane for the Biennial Period  
ending July 31, 1890.

Silver in the Forty-first Congress. **Preceded by a Summary of the Coinage Laws of the United States.** Issued by the National Executive Silver Committee. 1890.

A Guide to the Practical Examination of Urine for the Use of Physicians and Students. By James Tyson, M.D. Seventh Edition. Philadelphia: P. Blakiston, Son & Co. 1891.

Text-Book of Hygiene. A Comprehensive Treatise on the Principles and Practice of Preventive Medicine. By George H. Kohe, M.D. Second edition, thoroughly revised and largely rewritten. Philadelphia: F. A. Davis. 1890.

**Manual of Clinical Diagnosis.** By Dr. Otto Seifert and Dr. Friedrich Møller. Translated from the Fifth German Edition by William Buckingham Canfield, A.M., M.D. Second English Edition. New York and London: G. P. Putnam's Sons. 1890.

## Lecture.

KOCH'S TREATMENT OF TUBERCULOSIS.<sup>1</sup>

BY HAROLD C. ERNST, A.M., M.D.,

*Physician to Out-Patients, Massachusetts General Hospital; Instructor in Bacteriology, Harvard Medical School, etc.*

BUT to come again to the consideration of the local symptoms; the next class of cases in which this material is employed, is in surgical tuberculosis, either of the joints or of the bones. In such cases, if for example they be similar to one which some of you may have seen in Dr. Warren's ward, to whom the irregular temperature chart spoken of above, belongs, with caries of the rib, the question may be raised as to the existence of tuberculosis and an attempt to settle the point may be the reason for injecting the patient. The injection was followed by marked pain, great increase in amount of discharge, and there was an intensely disagreeable odor for a time. Whether the evacuated material contains the bacilli of tuberculosis, we do not yet know, but it will be possible to decide before long, because all the gentlemen who have been working in my laboratory are assisting in the work of systematic investigation of the cases in my charge. The marked increase in pain and amount of discharge are the especial things in surgical tuberculosis where there is any sinus at all. In cases where there are no sinuses, there is a marked increase in size of lesion and great pain, particularly inflammatory reaction, by that meaning heat and redness; and, finally, if the treatment has been persisted in for some time, a sort of necrosis apparently takes place about the tuberculous nodule, and in that way the tuberculous material can be let out by a simple incision, and emptied almost like a foreign body. If this material turns out to have the power, as it seems at present to have, of intimating the presence of tuberculosis by the production of either a general or local reaction, it is going to be of inestimable value to the surgeon and patient as a means of differential diagnosis; and here I should impress upon you very earnestly that the reaction spoken of as due to this material does not wholly refer to the reaction of the temperature. It is quite possible to have a chart following along the normal line, without any marked rise or fall. To have marked local changes going on and a local reaction, is just as important as the presence of a characteristic chart; and this fact has been much lost sight of.

Last, comes the consideration of what Koch's material does in cases of pulmonary tuberculosis. I am sorry to say that a large amount of the clinical material which is being collected in Berlin will be more or less unsatisfactory in helping us to determine this particular question. The reason is that in the hospitals there they are overwhelmed by the number of applicants for admission for treatment; and in the excitement attendant there have been a number of cases accepted, which will tend to throw discredit upon Koch's material, because they are in too advanced stages for treatment with any hope of recovery. It is quite necessary, to my mind, in order to have any knowledge of what this paratubercle can do in cases of pulmonary tuberculosis, to limit the experiments in the first place distinctly to a series of beginning pulmonary disease. Early apex catarrh, early localized

disease in the bases are the ones to be selected for treatment, and as far as has been possible, such cases only have been selected for treatment at the Massachusetts General Hospital and the Boston City Hospital. In pulmonary cases, it seems to me, besides what we can actually observe, it is only fair to take for granted that a similar process goes on in the lung as in the skin, bones, and joints. In pulmonary cases there is certainly to be observed a very marked increase in the expectoration, a great and most distressing increase in cough, not invariably certainly; but these are the things which attract our attention. The marked increase of the physical signs during treatment and their subsidence after treatment are the most interesting points in pulmonary cases. One of the patients of whom I have charge, showed this in a very interesting way by presenting no temperature reaction whatever, but he was able to point out and to trace upon his chest with the point of his finger precisely the limit of the lesions in his lungs. There was no deception about it, for only the day before a portion of the lung was discovered affected at the base, which the patient did not know anything about, and which he marked out perfectly. That was a very marked thing, and struck Dr. Tarbell, in whose service he is, as one of the most interesting things he had seen thus far. One of the unfortunate things which occasionally occurs in pulmonary cases, is hæmorrhage. As a rule when this does happen it is severe. Whether it is actually brought on by the treatment is hardly an open question, it seems to me. It must come as the result of an intense local reaction going on and which certainly occurs in the pulmonary tissue as it does in the external forms of tuberculosis. Sometimes this hæmorrhage is almost uncontrollable, but it is to be said that it seems to occur only in cases of second and third stages of the disease. I do not know of a case where it has been brought on in the early stages, which is confirmatory of what I have just said in regard to the importance of treating only the early stages of pulmonary tuberculosis.

Then, as treatment goes on, as one injection follows another, the natural course of the curve of the temperature chart on the following days, is usually a sharp rise, a sharp fall, gradually diminishing in extent until it reaches the normal line. The sharp rise follows each injection, and diminishes in intensity if the same dose is continued; therefore, the usual practice is to increase the dose if the patient can bear it, that is, if the condition of the patient after the first injection is good. If, for example, the first dose was one-half milligramme, the second would certainly be one milligramme, the third one and one-half milligrammes, and so on. This is followed, as a rule, by a rise of temperature to the same or a greater height than after the first injection; but if the dose is not increased, the injection is followed by a diminution in the rise of the temperature, or no reaction at all. When no reaction follows a large dose, reaction being marked after similar ones formerly, it is considered that the time for treatment to cease has come; and it is hoped to find, in cases of surgical tuberculosis where there has been an opportunity for discharge, that the tuberculous material has all been gotten rid of; or in cases of joint disease, as in one of the slides which I will show you, this tuberculous material will be surrounded by necrotic tissue. In the case of lupus the crusts fall off and leave a granulating surface ready to heal; in cases of pul-

<sup>1</sup> Lecture delivered at the Harvard Medical School, Saturday, January 10, 1891. Concluded from page 79.

monary tuberculosis, the bacilli have disappeared from the sputum, the physical signs have been diminished, and the patient is sent out and kept under observation—the material has done all that can be expected of it; and after the treatment is omitted, the ordinary methods of nutrition are carried out. Now, the only point that remains, and which can only be decided as time goes on, is the permanence of these beneficial effects. As to their occurrence, there can be absolutely no question if one can believe the evidences of his eyes and ears. That lupus patches do diminish, cicatrize, cease in activity, there is no doubt at all; that pulmonary symptoms are immensely benefited and in a more easy way than occurs under any other treatment, there is also no question. The only question is the permanence of these good effects.

Then, of course, following out the investigation of such a question as this, one of the first things to be decided is as to what are the pathological or anatomical changes produced by this material; in this direction we are as yet pretty well in the dark. It is quite certain that the newspaper reports which have come to us in regard to Professor Virchow's speech in Berlin Friday night are very much exaggerated. The papers report him as saying this material scatters the bacilli. It is impossible for it to do anything of the sort, and I do not believe Virchow said so. Hyperemia is a daily occurrence. What I think Professor Virchow meant was to emphasize the necessity for extreme caution in the use of such powerful material as this Koch's paratubercle certainly is, and the necessity for watching the cases with great care.

The microscopic changes, so far as they have been followed out, seem to be a shrinking of the tuberculous tissue. After treatment by this material, the cells, instead of being spread out as usual, will be thrown much closer together, and the rods will be in between them.<sup>2</sup>

In some of the clinics it is asserted that the form of the bacilli change after treatment by this material. An attempt was made to show these changes to me; but I must confess that to see it requires a much sharper eye than I have. I do not believe there is any change in the organism itself that can be made out at present. The granular appearance is in no degree different from what always, or not infrequently, occurs in the expectoration from patients with cavities in the lungs. It is not uncommon to see this broken up appearance resembling the organism of tuberculosis, and there is a little change in their appearance as it was shown to me. That is all that can be said in regard to the histology so far, and I have tried to say all that can be said in regard to the material. It may interest you to know something about its application and the methods adopted in using it.

In the first place, the back is selected for the injection of the material. Not certainly because it is easier to make an injection there, because the skin is very thick and tough, twice as much so as any other part of the body. But it is found that if there should be any local irritation at the point of injection, this part of the back between the scapula and vertebral processes is the place upon which the least pressure is apt to be exerted; because when the shoulders are thrown back there is a little hollow there, and most persons lie on one side and not directly on their backs. The

subcutaneous injection could be made anywhere but for this reason. In Berlin the back is prepared for injection in the first place, by being thoroughly washed with soap and water with a hand brush; then, just at the time of operation, the surgeon's hand is placed upon the back, the skin is stretched and thoroughly scrubbed with a solution of 1-20 carbolic acid. This is the only preparation I saw used in Berlin.

In this city, at the Massachusetts General and City Hospitals a little more technique is followed out. The preparation of the back of the patient is begun the night before by the application of antiseptic poultices. The hands of the operator just before handling the needle are very carefully sterilized by first washing them with soap and water, then by the use of corrosive sublimate (in my own case I use about 1-5000), and this is finally washed off in carbolic acid. It is pretty severe treatment for the skin of the hands, but it is about the only way in which one can secure safety in such cases as this. The syringe with which the injection is made is similar to the one shown. It consists of a rubber bulb with a hole which can be stopped up with the thumb, and a valve turned by the other thumb and finger, the cap attached to the valve fitting closely in the ground edge of the glass tube. In the recent modifications of the syringe, the needle fits on the other end of the glass tube. The older form has an extra shield, on which the needle fits. The fluid is drawn up by opening the valve, freeing the bulb of air, plunging the needle into the material, and, when you have enough, closing the valve.

The syringe used for the treatment is made to hold one cubic centigramme of fluid, and is also divided very exactly into tenths of a cubic centigramme. The syringe, itself, is sterilized before and after each patient is injected, in the first place with a half per cent. solution of carbolic acid in doubly distilled water, which is drawn up and down several times through the needle and syringe itself. The syringe is washed on the outside. The whole of the carbolic acid is washed off both inside and outside by as nearly absolute alcohol as chemistry can obtain. The nearest approach to that which is easily obtainable is Squibb's absolute alcohol.

It is an interesting point for you to know that so much is said about, and so much is done with material contained in a flask certainly not any higher than one and a quarter inch, containing five grammes of fluid. Koch's material is disposed of in Berlin in flasks containing only five grammes. By the dilutions, however, to which this material must be subjected, there are, of one milligramme doses, 5,000 in each flask. The dilution is accomplished by taking one-tenth of a gramme of the material and adding nine-tenths of a gramme of distilled water, giving one part in ten, and one gramme of fluid; to this is again added nine grammes of distilled water, giving one part in 100 or ten grammes of fluid; and again 90 grammes of distilled water, giving you one part in 1,000 or 100 grammes of the fluid. This is the regular standard method of dilution, and it can be varied as one chooses. A special point in regard to it is that the original material keeps indefinitely. After it has been once diluted, however, it decomposes within a moderate degree of time if one uses distilled water alone, and decomposition with the consequent loss of material can be guarded against by making the dilution with a half per cent. aqueous solution of carbolic acid. The method I have adopted is to make the dilu-

<sup>1</sup> See p. 104. <sup>2</sup> See Koch's Berlin 1914 on the "Tubercle." <sup>3</sup> See H. H. H. Koch's Berlin 1914, p. 104, Dec. 1, 1900.

tion with half per cent. solution of carbolic acid, divide the resulting 100 grammes of solution in sterilized test-tubes, stoppered with absorbent cotton and covered with rubber caps. These are sterilized after each opening for use, in a steam sterilizer for five minutes after the steam has began to pass. The sterilizer I use is the Arnold sterilizer. It is more effective than the ordinary one of Koch's, and the steam in it is under a slight degree of pressure and is raised to  $102^{\circ}$  to  $103^{\circ}$  C, so that sterilization is accomplished more quickly than in Koch's. It has been my experience, as well as that of those in Berlin, that by doing this, after each opening of the test-tube, the material keeps practically for a fortnight, so that a great deal of unnecessary and tiresome detail can be avoided.

It may be of interest to you to hear a very brief account of a few of the cases that I saw, which furnished a basis for the faith that I have that this material of Koch's is the introduction to us of a change in the medical treatment of disease, of which we have as yet no conception. I believe that this is only one of a series of discoveries of equal importance which will practically revolutionize the practice of medicine before you gentlemen are twenty years older. Further discoveries are more a question of time and endowment of research than of brains. In the first place this result is not a surprising thing to me. It has been in the air for several years. The whole knowledge which we have been gaining in regard to ptomaines, and the growth of bacteria, in various nutrient-media, has pointed to something of this kind, and it is extremely curious also to note that, as far-fetched as it may seem, Pasteur's laboratory is remotely responsible for this great discovery. The reason for this you will easily understand, when you are told that when the bacillus of tuberculosis was first discovered, the only material upon which it would grow was sterilized blood-serum. It was extremely difficult to get good results. The study of the bacilli in blood-serum could only be carried on by men who had all the apparatus necessary, and they were able to carry this study to only a limited extent. But some three and a half years ago there was announced from Pasteur's laboratory the fact that the addition of a certain per cent. of glycerine — six to eight per cent. of pure glycerine — to the ordinary nutrient media (nutrient-gelatin, nutrient-agar-agar), furnished as perfect a soil for the cultivation of the bacilli of tuberculosis as we could possibly desire. In such materials it developed very quickly, much better than in the ordinary sterilized blood-serum; and it was in this way only that the possibility of carrying out researches upon this organism was placed before so many people. At that time I made a prediction foreshadowing something of this kind. I was asked to go to Worcester and address the medical society there, and was permitted to choose my own subject. I chose Tuberculosis, and carried there a number of cultures of the bacilli in nutrient glycerine-gelatin, and nutrient glycerine-agar, and there I made the assertion that for the first time we were justified in hoping for some such result as has come, *because* of the increased ease with which the bacillus of tuberculosis could be studied.

Now, in regard to the cases I saw. The most interesting, were two of apex catarrh which had been under treatment for about six weeks. There had been marked dulness at both apices, of both cases I

think, certainly in one. Numerous moist râles were present and bacilli of tuberculosis were found in the sputa. After carrying on the treatment for six weeks, practically all of these signs had disappeared. There were no bacilli in the sputa, no râles, and although diminished resonance was still present, dulness had entirely disappeared. Reaction had ceased and then the bacilli had disappeared. In the other case there were a few râles left, and dulness was very much diminished. No bacilli in the sputa. These cases were not completely well of course; but so far as the physical examination showed, so far as the general condition of the patient was concerned, they had improved beyond anything which I had ever seen before in any case under treatment.

Then as an example of a different class, I saw a case of chronic pleurisy, accompanied by night sweats, dry cough, loss of appetite, where there had been no expectoration. After three or four treatments there was a great amount of expectoration and a large amount of bacilli. That was one of the cases in which a pulmonary tuberculosis had apparently been developed, and this chronic pleurisy was really a tuberculous pleurisy.

Then another very interesting case was one of incipient phthisis, containing many bacilli in the sputa. The treatment began with an injection of two milligrammes, followed by an injection of five milligrammes. The first treatment being followed by a very marked temperature reaction, but the second injection of five milligrammes, — a very large dose for such a case, — was followed by absolutely no change whatever. In three days afterwards a third injection was given, this time also of five milligrammes, and then reaction went on. There was a gradual diminution of the number of bacilli.

One of the most tremendous cases which I saw was one of ulcerative lupus of the face, back, and arms. It had been under treatment for six weeks, the dose running from one milligramme up to the last one given on the 22d of November, eight milligrammes, and no reaction following the last three injections. The ulcerations of the lupus tissue had completely stopped, and they were practically cicatrized before I came away.

Another striking case was one of lupus of the face, where the treatment had been going on for about eight weeks. In this case very large injections were made, the first was one centigramme of a one per cent. solution, — ten milligrammes of the material. This is a very large dose indeed, and even three centigrammes of this one per cent. solution were used. The result in that case was something nearly marvelous. In eight weeks the whole face was cicatrized; there was no reaction, no elevation of temperature, no swelling in the parts; and if one ever saw anything, one saw healthy skin amounting to at least two square inches in area, as islets among the lupus nodules.

Another case was one in which the diagnosis of tuberculosis was made because of the reaction to treatment by this material. There was a sprained (?) ankle, at which appeared a nodule, incision was made and the whole thing was taken out as if it was shelled out. The surgeon could almost follow a line of demarcation as a result following treatment.

The most striking case of all was one following nephrectomy in a boy of thirteen, who had had an abscess of the kidneys. Incision was made and the whole evacuated and cleaned out, and everything had healed

up perfectly. The cicatrix was solid. The boy was gaining in weight, and was about to be discharged, when as a matter of interest some of this material was injected. The reaction following was very marked, and after three or four injections, I do not remember exactly how many, there appeared in the cicatrix a tuberculous nodule about the size of the tip of my little finger. This dropped off and was proven to be tuberculous, and the cicatrix healed. There was no further reaction to treatment, and the boy went out, I believe, without any signs of disease. If the tuberculous material had remained within the cicatrix the chances are that something might have occurred to start the nodule into activity when it could not reach the surface and would be forced into the abdominal region.

It may also interest you to know something of the doses employed in Berlin; and to that end I read you some extracts taken from my note-book; the doses are given in milligrammes of the *undiluted* material:

(1) M., phthisis, with cavities in the left lung.

Nov. 29 . . . . .	1 mg.	Nov. 26 . . . . .	4 mg.
" 21 . . . . .	2	" 28 . . . . .	10
" 23 . . . . .	5	Dec. 1 . . . . .	10

(2) T., lupus, eight weeks under treatment, ulceration almost stopped.

Nov. 4 . . . . .	1 mg.	Nov. 20 . . . . .	1.5 mg.
" 6 . . . . .	1	" 22 . . . . .	2
" 9 . . . . .	1	" 24 . . . . .	1
" 12 . . . . .	1	" 25 . . . . .	2
" 16 . . . . .	1.1	" 26 . . . . .	4
" 18 . . . . .	1.4	" 27 . . . . .	8

No reaction after the last three injections.

(3) S., osteomyelitis, scraped out, and then tuberculosis of the lungs suspected, proved by the injections and the physical signs.

Nov. 21 . . . . .	2 mg.	Dec. 3 . . . . .	5 mg.
Dec. 1 . . . . .	4	" 1 . . . . .	5

(4) T., parotid abscess (control case).

Nov. 26 . . . . .	1 mg.	Nov. 20 . . . . .	18 mg.
" 27 . . . . .	5	Dec. 3 . . . . .	20
" 28 . . . . .	10	Dec. 4 . . . . .	30
" 29 . . . . .	14		

No reaction after any injection.

(5) B., tuberculosis of ankle.

Oct. 12 . . . . .	1 mg.	Oct. 16 . . . . .	3 mg.
" 13 . . . . .	2	" 18 . . . . .	1
" 15 . . . . .	2		

From November 3d to 7th, erysipelas.

Nov. 17 . . . . .	8 mg.	Nov. 21 . . . . .	9 mg.
" 19 . . . . .	10		

Operated upon on 21st.

Nov. 25 . . . . .	12 mg.	Nov. 30 . . . . .	28 mg.
" 27 . . . . .	20	Dec. 3 . . . . .	30

No reaction.

(6) F., of knee, tuberculous (?).

Oct. 1 . . . . .	5 mg.	Nov. 13 . . . . .	10 mg.
" 14 . . . . .	10	" 18 . . . . .	11
" 21 . . . . .	10	" 22 . . . . .	20
" 24 . . . . .	10	" 26 . . . . .	10
Nov. 1 . . . . .	10	Dec. 2 . . . . .	50
" 8 . . . . .	10	" 3 . . . . .	50
" 10 . . . . .	10	" 8 . . . . .	50
" 12 . . . . .	10		

No marked reaction at any time, except on October 21 and 23d and November 1st. Between October 21st and 23d, the temperature was 36.3° C., or subnormal.

As good a picture of what may occur as can be given is furnished by the notes of the first injection of the case of lupus, the photograph of which I have just

shown you upon the screen. I will therefore read them to you. They were taken by Dr. Abbot, with whom I was, at the bedside.

The case was one of sixteen years' standing, extending over the nose, both cheeks, and under the chin passing into the mouth and attacking the gums, pharynx, and larynx, — the vocal cords were almost destroyed. The general appearance before the first injection was that of an ordinary subacute process.

December 9, 1890, 9 A. M., received one milligramme injection. At 4.30 P. M. the general appearance of the lesions was that of an acute process, there was shivering in an ague fit, the face was intensely red, the reddening being confined to the diseased parts, with the healthy skin but little altered. There was serous exudation from several ulcerating points and from the angles of the mouth. There was headache, pains in the joints, a diffuse exanthem upon the arms and breast. Temperature 38.5° C. (Westphal says that according to his observation, the chills occurring after the first or second injection average two and one-half hours in duration.)

On the following morning the above condition was but little altered. Temperature 38.2° C. at 9 A. M. There was still slight exudation and some swelling, but the tension was much diminished. The patient slept poorly but feels better than he did in the night. Persistent, irritant cough has appeared, perhaps owing to the action of the material upon the larynx. The reaction is passing away much less rapidly than is ordinarily the case. The exudate is beginning to dry, and is quite markedly so upon one of the larger spots of ulceration.

The general condition of the patient on the following day was much improved. Temperature gradually sinking to normal, the thickness of the diseased skin much diminished, as well as the reddening. Over that portion of the diseased processes which was fairly smooth before the injection, there are now numerous evenly scattered dry, whitish scales. (This is the usual result at the edges of the lupus patches after treatment with Koch's material.)

The following morning (December 11) the general condition of the patient was sufficiently improved to admit of a second injection of one milligramme of the material. At the time of the injection, with the exception of the dry scales on the smoother portions of the process, the local condition differed but little from that at the time of the first injection.

This, gentlemen, concludes what I have to say upon this subject this evening. I thank you for your attention, and trust I have been able to explain some of the points in regard to it to your satisfaction.

NOTE. — My hearty thanks are due to Drs. Klemperer and Westphal, for the extreme courtesy shown to Dr. Abbot of Johns Hopkins University and me, and for the facilities placed at our disposal for observing the cases under their care.

H. C. E.

THE French Parliamentary Committee appointed to report on the new Bill have pronounced against the retention of the Article authorizing foreign practitioners accompanying their patients to French health resorts to practise without having obtained a French medical degree.

THERE has recently been organized in Russia a Medical Woman's Society, which owes its origin to the efforts of Doctoress Rodstvenmajaschenkaskaja.

## Original Articles.

CASE OF EXTRAORDINARY ACCUMULATION OF FÆCES.<sup>1</sup>

BY SAMUEL L. ABBOT, M.D.

THE patient was a young lady about thirty years old, under-sized, of small frame, with slender muscles, and of marked nervous temperament. Her usual weight was a little under a hundred pounds. Her complexion was sallow and her appetite poor. The catamenia had failed to appear when last due for the first time since the function had been established. I was told by her mother that, supposing she was suffering from dysentery, her daughter had been taking a "cholera mixture" during the previous fortnight. The discharges had been very frequent, of a dark color, tarry looking, accompanied by great tenesmus.

The young lady had occasionally obtained from me during the past few years a recipe for a laxative while I was attending another member of the family, to relieve habitual constipation. On the present occasion her mother informed me that when her daughter was eighteen months old, she had consulted her physician on account of a difficulty in defæcation in the child, which led him to make an examination. He found, as he said, a malformation in the intestine which made evacuation difficult, but advised non-interference as he had known such a procedure in a similar case lead to a fatal result. Of the various remedies which she had taken, saline laxatives, especially sulphate of magnesia, had been the most effectual, and this she had had recourse to very frequently. I saw the motion passed just before my arrival, which was small in quantity, thin, brown, with some small fecal scraps, and very offensive.

Thinking there might be a fecal accumulation I asked to be allowed to make an examination, which was with much difficulty at last permitted. On putting my hand on the abdomen I found it to be apparently filled by a large, solid, pear-shaped mass, which suggested for a moment the presence of some morbid growth complicating or causing an obstruction of the bowels. The mass extended from the pubes nearly to the ensiform cartilage, and from one ilium to the other. The patient was very nervous and timid, constantly interrupting my examination, so that it was with some difficulty I found that its surface was a little irregular, of somewhat unequal density on pressure, with slight depressions here and there suggesting spaces between folds of intestine. In the left iliac fossa it was somewhat less prominent and quite tender on pressure. The tumor was very prominent anteriorly, most so between the epigastrium and umbilicus (as much so as a pregnant uterus would be from the fifth to the sixth month), so that the patient had been unable to wear her corsets for some time previously. Percussion was perfectly flat over the whole area and the mass felt more like a block of wood than anything else, being in most places entirely yielding on pressure, without the elasticity or smoothness of an organic growth. My diagnosis was a colon probably filled with hardened feces.

With some difficulty I obtained permission to examine the rectum. On passing my finger within the anus it was stopped at a point an inch above by what seemed to be a cul-de-sac. Up to this point the intestine was

easily dilated, soft and apparently normal in structure. It was not easy to find a passage upward owing to the constant resistance and starting of the patient, as the whole fundus of the cul-de-sac was very tender. At last the tip of my finger with a little pressure entered a small opening about in its centre and came at once against a mass of pretty firm feces. The cause of the difficulty was thus found to be a congenital diaphragm across the lower portion of the rectum, with a small opening in the centre. There was no hardness at the opening and the intestine about it felt perfectly natural to the touch. The tenesmus from which the patient had been suffering and the frequent small liquid evacuations had led her to take frequent doses of the medicine which probably contained opium.

The question now presented itself how to relieve the difficulty. The passage in the rectum was too small for any effectual scooping out of the obstructing mass which apparently filled it to its fullest capacity. I determined therefore, to give saline laxatives persistently, day after day, so as to produce free watery discharges, which passing down between the intestine and its indurated contents might gradually soften them on the outer surface and so wash them away. This was accordingly done. The first dose was three teaspoonfuls of sulphate of magnesia, which was followed by two double Rochelle powders,—the latter taken by the patient because of the somewhat dilatory action of the dose. The result was very large watery evacuations, followed by a small amount of substance of the consistence of gruel. After this, felt through the clothing, the abdomen seemed to be a little less full and hard. The same treatment was continued, and after two or three days it became necessary to give a small amount of opium to relieve the pain and tenesmus excited by the frequent evacuations day and night. Then a change was made to the solution of citrate of magnesia, of which a whole bottle acted freely, bringing away much tarry-looking matter, very offensive. There was most of the time a good deal of throbbing sensation in the lower rectum.

On the ninth day my notes show that the patient was taking again the three teaspoonfuls of Epsom salts every second night, which produced free liquid dejections the next morning, of the same character as above described; but the rectum still remained packed full. The patient was a good deal exhausted by the treatment, was very nervous and wakeful at night, and required stimulants and nerve sedatives, such as brandy and the ammoniated tincture of valerian to keep her up.

On the thirteenth day the discharges were very free and less watery. The abdomen was very much distended with gas and no hard masses could be detected except in the left iliac fossa where the tenderness on pressure was much less. Four days later, the abdomen being still much distended with gas, on deep pressure a soft fulness could be felt, and there was still some resistance on pressure in the left iliac fossa, with very slight tenderness. At this time her appetite which had been very small from the first began to revive. The laxatives were continued and three days after she had become very hungry, was in excellent spirits and much stronger.

Two days later my notes show that she had three loose dejections after taking half a bottle of solution of citrate of magnesia. On the twenty-fifth day of treatment the first formed fecal evacuation appeared, of

<sup>1</sup> Read before the Boston Society for Medical Improvement, December 8, 1890.

the diameter of a clinical thermometer case. During the fourth week of treatment the catamenia appeared.

At the end of six weeks the patient was in excellent health and spirits, her mother declaring that she had never seen her so well. The evacuations were still as small in diameter, requiring a little persuasion at times by a moderate saline cathartic, at times easily moved by a little molasses and water, and often without artificial aid. The course of treatment was one of considerable suffering and exhaustion from the frequency of the evacuations and the constant tenesmus from the pressure downwards of the fecal mass in the rectum, which was the last of the intestinal contents to disappear. At times it was necessary to withhold the laxatives for a day or two and give opiates. The diet was mostly liquid, milk and broths, with a little solid food and fruit.

Under present conditions the patient is not inclined to submit to any surgical experiment for relief. The distension of the intestines with flatus as the hard mass worked off was reduced by the use of strychnine and other tonics. At the present time her health is excellent.

## TWO CASES OF PELVIC HÆMATOCELE.

BY JOHN HOMANS, M.D.,

*Surgeon to the Massachusetts General Hospital, and Harvard University Lecturer on Ovarian Tumors.*

THESE reports illustrate well the difference in the behavior of cases before and since the introduction of anti-septic surgery, — one going through a long, tedious, and dangerous process of recovery, and the other being immediately relieved, and cured almost at once.

**CASE I.** Incision and drainage through the vagina: cure.

Honora G., married, age thirty-eight. Entered the Carney Hospital, April 23, 1874. Never pregnant.

On the first of March, 1874, at 6 p. m., she was suddenly attacked with severe pain in the left iliac and hypochondriac regions. She felt, she says, as if something fell with a rush from the left hypochondrium downwards. A physician was called at three o'clock the next morning. She vomited for four days; the pain lasted about ten days. A tumor was noticed, very tender, about the size of an egg. At the end of a fortnight it had increased to the size of an orange. At the end of ten days she began to go about a little, but was attacked with chills.

On April 23d she was etherized, and a tumor was punctured in the left pubic region. About six ounces of dark, reddish-brown fluid was removed by aspiration; then another puncture was made in Douglas's space, but only a few drops of fluid was obtained. This fluid contained recent and old blood-clots and many vibrios. She rested fairly well, but the next day her tongue was dry and coated.

On April 26th, the tumor had increased in size, and was quite hard. Temperature 103°. She was again etherized, and tapped through the vagina, to the left of the uterus, with a larger trocar. Twenty-four ounces of dark, bloody, offensive fluid were removed.

On April 30th, the tumor was hard and painful, and the patient was suffering greatly. I was sent for late in the evening. The patient was etherized with the assistance of Dr. D. H. Hayden, and again tapped through the left portion of the vagina, to the left of the os-uteri. The opening was then enlarged with

a knife so that it would admit the finger. About twenty-five ounces of very offensive bloody fluid were removed, and a large œsophageal tube, three-eighths of an inch in diameter, was passed into the cavity to a distance of three and a half inches beyond the vaginal septum; the tube was tied in, and the cavity thoroughly irrigated. Constant irrigation was practised; and on May 4th the tube was removed. The discharge continued, — at first healthy, inodorous pus, which in a few days became offensive.

On May 22d she went home; and on June 17th reported herself having gained flesh and strength, and being entirely well except for a slight inoffensive discharge.

**CASE II.** Treated by free incision through the vagina: cure.

Catharine C., married, age twenty-seven. Mother of two children, youngest eighteen months old. Entered the Massachusetts General Hospital just after midnight, April 5, 1889, and Dr. Homans was at once summoned.

She stated that she was well until seven weeks before entrance, when immediately after a menstrual period, and without any unusual exertion, she was seized with a very sharp pain in the right side of the abdomen, lasting some hours. She felt feeble for some days but kept about and did her work. Five weeks later, that is, two weeks before entrance, she had another severe attack of pain in the same spot, and then for the first time noticed a swelling, small at first, which increased slowly in size until during the past few days, since which time it has grown very rapidly. For two weeks past she has had an offensive vaginal discharge. Two days before her entrance she was tapped by a physician, and a little bloody fluid was obtained. On examination she appears to be a large, strong woman. Her face is pale and anxious looking; her abdomen is much distended, and is rather more prominent on the right side than on the left; it is tender to the touch. By palpation a smooth swelling is felt in the lower part of the abdomen with a slight sensation of fluctuation. Over this area there is dullness, and also in both flanks. The upper part of the abdomen is tympanitic. On auscultation nothing is heard. On pelvic examination the uterus is found lifted up behind the pubes, and the vaginal cavity is almost obliterated by a soft, tense, semi-fluctuating tumor which fills the pelvis and presses forward almost to the vulva. Her last catamenial period was four weeks ago. Micturition has been frequent for the past few weeks; during the same period she has had almost incessant vomiting and no movement of the bowels. Pulse 120, rather feeble. Temperature 103.6°.

Diagnosis: Pelvic hæmatocele, from probable rupture of an extra-uterine pregnancy.

She was at once etherized, and the prominence of the swelling at the vulva seemed to invite opening at this point. She was placed in the lithotomy position and the vagina thoroughly drenched with a solution of corrosive sublimate. The tumor was then aspirated through the vaginal wall and dark bloody fluid was withdrawn. The opening was then enlarged by passing a knife in alongside the needle, then this opening was dilated and the finger inserted. Large quantities of clots were emptied out. After about two hours hard work the clots were pretty much cleared out, and the cavities which they had occupied were swabbed out with sponges and irrigated with corrosive sub-

limate solution. The tumor had disappeared. There had not been much hemorrhage. A large double rubber drainage-tube was put in, and prolonged irrigation was practised; and finally iodoform was blown into the vagina, and the wound was dressed with iodoform gauze. After the operation the patient, who was pretty feeble, was put to bed with heaters around her, and an enema of brandy and laudanum was given. By estimation, about two quarts of clots and bloody fluid had been removed.

The operation was over at about one o'clock in the morning. As the day went on, the pulse became much stronger, and the patient became perfectly comfortable. The drainage-tubes were frequently syringed.

On April 7th the bowels moved, and the temperature, which had been 103.5° at the time of the operation, became normal. On the 11th, there was no discharge, and the drainage-tube was removed. On the 14th, she sat up out of bed; and on the 19th, as she was very anxious to return home, she was discharged with orders to take a daily douche, and to keep as quiet as possible for two weeks.

This case is not reported for the sake of encouraging vaginal operations in cases of pelvic hemorrhage; but, as no hemorrhage was apparently going on at the time of the operation, and as the first attack had been five weeks before, and as the bag of blood was almost protruding between the vulva, it seemed to me best to empty out all the effused blood, and then, if hemorrhage was found to be going on, to do laparotomy if I found it impossible to stop the hemorrhage from below. The result of the operation left nothing to be desired.

#### CYST OF THE PANCREAS TREATED BY LAPAROTOMY AND DRAINAGE; RECOVERY.<sup>1</sup>

BY MAURICE H. RICHARDSON, M.D.,  
*Surgeon to the Massachusetts General Hospital.*

DAVID C. L., aged fifty, married, living in Stoneham, was sent to me by Dr. Jordan, of Wakefield. I made several examinations and finally advised him to enter the Massachusetts General Hospital; this he did on October 10, 1890.

Family history good, except that mother and sister had scrofula. The patient had typhoid fever at the age of fifteen. Lost an arm in the war, in 1863. Average weight up to nineteen years ago was a hundred and fifty to a hundred and seventy-five pounds; since then average weight two hundred and ten pounds. Up to about five years ago had been perfectly healthy, but five years ago last spring felt something give way in the epigastric region while lifting a heavy weight. At first he felt faint, and was troubled by this feeling for a number of days afterwards. Shortly after this he had a fall, which, as he says, "knocked his breath out." Three or four months after this accident he began to have pain in the epigastrium, varying a little in position, sometimes shooting backward. Had only four or five attacks at that time. The pain would be relieved by mustard poultice. In May, 1889, he had attacks of severe pain in the same place, which lasted from three to seven hours, associated with vomiting, which was relieved by hot applications and morphine. For nine weeks he had an attack every week. He noticed before that time that the urine contained brick-dust

sediment and was high-colored. He often had diarrhea the day after the pain, and was sore over the epigastric region. After nine weeks the pains gradually became less frequent. Last January he had an attack of pain which was constant during three days. There was considerable vomiting, which required morphine subcutaneously. He said that he stiffened right out with the pain. At that time he was jaundiced. He was completely prostrated after this attack; extremities were cold, covered with cold perspiration, followed by "fever in the stomach, which worked up and caused a funny sensation in the head,—a dizzy feeling." Many times since, in the morning, he has had a faint feeling and a sensation of weight in the stomach, relieved by eructations. Within the last year and a half has felt as if there was a tight bandage around his belly. Bowels have been generally loose except in January, when they were constipated. Stools have been at times very light-colored, but never quite clay-colored. Appetite from January to June has been very poor, and since then gradually gaining. He thinks his memory has been slightly affected. Since January has lost fifty-three pounds.

Physical examination:—A large, powerful man, apparently in excellent condition. The epigastrium is occupied by a prominent mass as large as a four-year-old child's head, extending slightly under the margin of the ribs and down nearly to the umbilicus, hard to the touch and slightly elastic. The tumor is deep-seated and slightly movable. Gurgling is felt and heard at times over it; on deep inspiration it moves down about four inches. Examination of head, lungs and kidneys, negative.

On the 19th of October the patient was seen by Doctors Porter, Fitz and Cutler. The colon was distended with air, and afterwards with water, and the stomach filled with air. By percussion the tumor was thought to be behind the colon and the stomach. No fat was found in the stools after repeated examinations.

On the 22d, after the administration of cathartics and after an enema, the rectum was filled with water by Dr. Cutler. This, by percussion and palpation, showed the colon to be in front of and over the tumor. The stomach was then filled with air and appeared to be in front of the tumor. Diagnosis by Dr. Cutler: Pancreatic cyst. Exploratory laparotomy was advised.

October 24th, 1890. Under ether anaesthesia an incision four inches long was made in the median line, three inches below the ensiform cartilage. The omentum between the stomach and the colon was torn apart with the fingers, making an opening down to the tumor, which was found to be a rounded, fluctuating cyst of the pancreas, entirely adherent to the posterior wall of the stomach above and in front, and to the transverse colon below. A very small aspirating needle was introduced, from which a fine stream of clear, straw-colored fluid spurted at least a foot into the air. The tumor was emptied, as far as possible, by means of the aspirating needle. The opening was then enlarged and a glass drainage-tube inserted. No stone nor other foreign body could be detected in the cyst. The edges of the opening were brought up and stitched to the abdominal wall. The edges of the wound were brought together with wire and superficial silk sutures. Syphonage was so arranged as to prevent any leakage of fluid. A dry dressing was applied.

The patient rallied immediately from the operation

<sup>1</sup> Read before the Boston Society for Medical Improvement, December 8, 1890.

and made an uneventful recovery. There was a good deal of discharge from the cyst, which was kept as far as possible from the edges of the wound by means of syphonage and a rubber dam. The fluid was examined and found to have the characteristics of pancreatic fluid. On the 26th day of November he was discharged, with a small sinus.

This case is one of considerable rarity. It was interesting on account of the difficulties in the way of diagnosis. It illustrates again the value of exploratory operations in doubtful cases. The question has arisen in connection with this case as to the advisability of aspirating such tumors. The fact that the cyst was so tense as to throw a stream of fluid a considerable distance through the needle seems to me to show that aspiration even with a small needle, through the abdominal wall is a dangerous one if there is anything septic in the fluid. If the cyst had been aspirated beforehand I am convinced that there would have been a large escape of the fluid into the abdominal cavity. The method adopted for drainage was perfectly successful and obviated the dangers of the use of the aspirating needle. The case was studied some weeks before entrance into the hospital and two weeks or more after admission, and an exploratory incision was advised only after the most careful consideration. In regard to the diagnosis, my own opinion, expressed before the operation, was that this was a malignant growth, and that nothing would be accomplished by the operation beyond establishing the diagnosis.<sup>2</sup>

## RECENT PROGRESS IN LEGAL MEDICINE.

BY F. W. DRAVER, M.D.

### PERSONAL IDENTITY.

*Identification by Means of the External Ear.*—Bouland proposes<sup>1</sup> a modification or extension of the well-known anthropometric method of Bertillon for the identification of criminals. He states that all parts of the human body except the external ear are subject to change in growth and appearance; the ear reaches its full growth early and is thenceforward constant in its size and shape. He has made a great number of measurements of the different parts of the pinna, the lobule, the helix, the tragus, the antihelix and the anti-tragus, and he finds it extremely rare to discover any two individuals with measurements of these parts identical; indeed, the two ears in the same person are not always symmetrical. Recalling, furthermore, the fact that the external ear is the organ by which parental likeness is frequently transmitted, we may see another direction in which careful observation of the dimensions of the various constituent elements of the external ear may be of medico-legal service.

*Identification of Bakers.*—G. Ranzier<sup>2</sup> describes an appearance about the hands of bakers that may be useful in identifying that vocation. His attention was first called to it by a fever patient, a baker, who had on the dorsal surface of the articulation of the first and second phalanges of each finger a large, round callosity covering the width of the finger. It was a hardening of the epidermis without involving the deeper struc-

tures and it almost disappeared during his two months' rest while sick with the fever. When questioned concerning these callosities, colloquially known as *bastels* or *coissinets*, the boy said that bakers always had them. This statement was subsequently verified. The repeated shock of the flexed fingers against the dough in the act of kneading produces this change. The author states that writers on professional stigmata have not referred to this mark of the baker's trade.

### IDENTIFICATION OF HUMAN BLOOD.

Professor Ewell,<sup>3</sup> thus summarizes his views upon this subject: "In the use of the micrometric test, no confidence can be placed in the result unless the errors of the micrometer used, with reference to authentic standards, are known. Instruments used in investigation should be described. Where the subject [from whom the blood is derived] continues during a short period in substantially the same condition of good health, there appears in the hands of the same observer to be an average size of the *fresh* corpuscles, provided at least one hundred corpuscles are measured. There are such great discrepancies between the averages obtained from the measurement of the *fresh* blood-corpuscles of animals of the same species and between measurements of the same objects by different observers, as to throw doubt upon published results. Several tables of measurements can be given to prove this statement. There is no advantage in using very high powers in such investigations. Drying of the blood-corpuscles in a clot multiplies the difficulties of identification. It has never been proved that dried corpuscles can be restored to their normal proportions. The mean size of the red corpuscles of very young animals is larger and their size varies between wider limits than in adults. Many diseases alter the size of red blood-corpuscles. Fasting diminishes the size and number of red blood corpuscles as, also, do many drugs. It is impossible in the present state of science to say of any given specimen, fresh or dry, more than that it is the blood of a mammal. Other conclusions are scientifically indefensible."

### RUPTURES OF THE MEMBRANA TYMPANI, WITH SPECIAL REFERENCE TO THEIR FORENSIC IMPORTANCE.

Dr. L. Treitel has contributed an article on this topic, in which he reports eighteen cases occurring in a single year.<sup>4</sup> Of these eighteen cases, only two were examples of direct injury. These two instances were cases of injury by the insertion of hair-pins into the auditory meatus. The other perforations were of the kind known as indirect, being due to blows on the ear and various forms of concussion. The traumatic perforations of the membrane make up from one to two per cent. of all ear cases. In some instances, a fracture of the skull is found to be continued directly upon the tympanic membrane. In one case quoted, the perforation was caused by diving. "Boxing the ear," was a cause of the lesion in the great majority of all the examples. Medico-legally, these latter cases raise two questions: (1) Is the disability produced to be regarded as a permanent one; (2) was the ear, injured by the blow, previously healthy? The author doubts if it is the diseased membrane only that is liable to rupture by a blow upon the ear. It is not easy, however, in his opinion, to judge of the state of the membrane before

<sup>1</sup> *Gazette Med. de Paris*, September 13, 1890.

<sup>2</sup> *New York Medical Record*, September 27, 1890.

<sup>3</sup> *The London Medical Opinion*, 22, 1891. "David C. L., is quite smart, but the sound is still open and continues to weep more or less daily."

<sup>4</sup> *Medical Standard*, September 1890.

<sup>5</sup> *Amer. Jour. Med. Sci.*, January 1891, from *Archives of Otolaryngology*, April and July, 1890.

the injury in any case; ears which hear well will often show an abnormal appearance of the membrane. It is stated by him that the sound-perceiving parts of the ear can be simultaneously affected in most cases of rupture of the membrana tympani.

The rupture heals generally in from three to six weeks, according to Treitel. The cicatrix may remain visible as long as seven months, although this must be regarded as exceptional; as a rule, no cicatrix is visible.

#### DEATH BY DROWNING.

*Condition of the Eyes in those Dead by Submersion.*—Seydel describes what he regards as a new proof of death by drowning.<sup>5</sup> He found the appearance about the eyes of twelve persons who were drowned and whose bodies he examined. The deaths occurred in spring and summer and the corpses were inspected whilst quite fresh. The eye-lids were sometimes of a bluish-red color and slightly swollen, sometimes they were unchanged and partly open. On that portion of the cornea which was uncovered, twelve or fifteen phlyctenular elevations, the size of hay-seed, and of a gray color, were observed. In the less recent cases, the epithelium over these spots had been destroyed, and the surface of the corneal tissue was shown. After enucleating the eye-balls, it was seen that the portion of cornea covered by the eye-lids was clouded and covered with a swollen epithelial layer. These appearances were more clearly seen when the eye-ball was placed for some hours in fifty per cent. solution of alcohol. The conjunctiva was injected, especially in its periphery. The color of the injected membrane varied from pale red to dark violet, according to the length of time during which the body had been exposed after removal from the water. In two cases, star-like, blue-red ecchymoses were seen under the injected surface. Whether similar appearances are to be found in bodies drowned in winter is uncertain, but, if so, probably a longer time would be required for their development than in warm weather.

*A Case of Extraordinary Recovery.*—The following case is recorded in the *Lancet*.<sup>6</sup> "The body of a man who had been capsized from a sailing-boat on the Thames, was picked up by a boatman, who towed it ashore behind his boat. A medical man saw the body on shore, and confirmed the boatman's view that life was extinct. Two bystanders, however, who were more sceptical and more sanguine than the others, immediately commenced the vigorous application of restorative treatment. In two hours, their diligence was rewarded by visible signs of returning animation in the man. Further treatment was pursued and the man is now alive. The obvious warning cannot be too often reiterated, that those engaged in the resuscitation of the apparently drowned should not be easily discouraged in their efforts."

#### PERSISTENCE OF THE HYMEN THROUGH PREGNANCY.

Destarac has collected forty recorded cases of this abnormality.<sup>7</sup> He has been careful to include those cases only in which the ostium vaginae was so thoroughly occluded by the hymen as to resist effectually any penetration in intercourse. In the majority of the instances cited, the hymen, though presenting a minute orifice, so fully closed the entrance to the vagina that the ac-

coucheur, called to the woman in labor, found this tough membrane in the way of a digital examination.

French law makes a distinction between a rape and an indecent assault, the rupture of the hymen, or defloration, being the differential distinction according to which the assailant is accused and, if convicted, is punished. These cases of persistent hymen show the error of this arbitrary classification, which is made to depend not only on the amount of unlawful force exercised by the assailant, but also on the resistance offered by a more or less fibrous membrane. Garimond proposes to apply the term rape (as the English and American authorities do), to all kinds of violence exercised upon the female sexual organs, whether much or little is accomplished, the intent being the same in all cases.

#### ABNORMAL DURATION OF PREGNANCY.

Ingley-Mackenzie<sup>8</sup> reports a case of prolonged gestation. The woman was thirty-two years old, a primipara, married ten years, and had always menstruated regularly. Her last menstruation previous to her confinement was April 28th. She felt the fetal motion in September. She had false pains in January. She was delivered March 8th, after a labor of sixty-six hours, her pregnancy having continued three hundred and fourteen days.

Pürkhauer<sup>9</sup> records a similar case. A married woman, aged twenty-six, of small stature, the mother of two children, had menstruated regularly every twenty-eight days and had had her last catamenia April 28th. She felt fetal movements at about September 15th. These movements ceased in December, although the fetal heart-sounds were distinctly audible. On the thirteenth of March the woman was delivered of a living male child, weighing eight pounds twelve and a half ounces, and measuring nearly twenty-one inches in length. If the fifth of May be taken as the date of conception in this case, the duration of the pregnancy was three hundred and sixteen days.

#### PRECIPITATE LABOR AND INFANTICIDE.

Haidenham<sup>10</sup> relates the following case: An unmarried woman was seized with labor pains in the middle of the night, and got out of bed to obtain a light. She alleged that while she was doing so, the child was suddenly born and fell upon the floor, the umbilical cord being broken at the moment the child fell. The mother returned to her bed and fainted, remaining unconscious for a time and when she came to herself the child was dead. The post-mortem examination of the child's body showed that it was at full term, that it had breathed and that the cause of death was inter-cranial hemorrhage resulting from mechanical injury to the skull, especially the left parietal bone. Haidenham regards with suspicion the stereotyped report of fainting after the birth of illegitimate children, and the continuance of unconsciousness in the mother until the infant is dead. He compares such cases with cases of labor among married women. Of three thousand labors which he has verified, in one only was there post-partum fainting, and that was in a delicate young primipara, who had lost much blood. He regards true precipitate labors, in which the child is expelled without warning, as very unusual, especially so in primi-

<sup>5</sup> Vierteljahrsschrift f. Gerichtl. Med., April, 1890; Medical Chronicle, June, 1890.

<sup>6</sup> *Lancet*, December 13, 1890, p. 1262.

<sup>7</sup> *Journal de Med. et de Chirurg.*, August, 1890.

<sup>8</sup> British Gynaecol. Jour., February, 1890.

<sup>9</sup> Friedrich's Blätter f. Gerichtl. Med., heft 3, 1890.

<sup>10</sup> Vierteljahr. f. Gerichtl. Med., October, 1889; Med. Chron., July, 1890.

paræ. He also thinks that the position of the fracture of the skull is suspicious, when the jerk which would be given to the body at the moment of rupture of the umbilical cord is taken into consideration. On the other hand, the limited nature of the injury to the skull is in favor of the woman's account, as infanticide is usually attended with greater violence. The opinion given is that the child lived a short time after birth, the full expansion of the lungs being in favor of a more prolonged period of respiration than would transpire in the act of falling from the mother to the ground; and that the umbilical cord was torn across by the hands, the injury to the head being subsequently produced by intentional violence.

### Clinical Department.

#### A CASE OF SPINA BIFIDA.

BY WM. H. LATHROP, M.D., LOWELL, MASS.

THE child whose photograph I send you herewith was born December 19, 1890, in Lowell, Mass. The parents are healthy, and have three other perfectly formed and healthy children.

The occipito-frontal circumference of the child's head was at birth twelve and a quarter inches, while the circumference of the tumor was thirteen and three-quarter inches, so that the tumor was slightly larger than the head. The contents of the tumor seem to be entirely fluid. The pedicle is thick and large, its largest diameter being two and one-half inches.

The child was born naturally, though the labor was rendered somewhat difficult by the fact that the tumor threw the head into a face presentation, the chin forward. The child is well nourished, nurses well and is otherwise perfectly formed.

A case very similar to this occurred in my practice at the Wayne County (Mich.) Almshouse in 1873, and was then reported in the *Western Medical Advance*. The woman was a primipara, twenty years old. There was no instrumental interference though the face presented. The tumor was somewhat larger than this recent case, it being fifteen inches in circumference; the pedicle, however, was only two inches in circumference. The tumor was removed and the parts stitched to-

gether, taking care to avoid the brain meninges, which extended into the tumor about an inch. The child was not strong and gave little promise of life in any case. It died in about twenty-four hours after the operation. The autopsy revealed an opening at the centre of the occipital bone, oval in shape, three-eighths of an inch in its longest diameter. This opening was undoubtedly

at the "centre of development" where in early foetal life there was a space between the four parts going to form the occipital bone.

The accompanying cut is taken from a photograph, the head having been stuffed with cotton to preserve its shape.

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, December 8, 1890, Dr. W. L. Richardson in the chair.

DR. ABBOT reported a case of

#### EXTRAORDINARY FÆCAL ACCUMULATION.<sup>1</sup>

##### A PIN IN THE LARYNX.

DR. HOOVER: Last month a woman came to me from Fall River, stating that five weeks previously, while eating dinner, she had swallowed a bone. She was quite hoarse, and had had constant pain on swallowing. With the laryngoscope I saw what looked to me like a pin, which was directly across the larynx from before backwards, one end of the pin sticking into the middle of the inter-arytenoid space, and the other end just above the vocal cords. There was considerable inflammatory swelling about the arytenoid cartilages, and in the inter-arytenoid space there was a projection of granular tissue which covered about one-third of what I took to be the pin. The foreign body was seized with the laryngeal forceps, but failed to come away, as the instrument slipped off. At the second trial a firmer hold was taken, and with considerable force I brought away this large-sized pin. You will see that it is slightly bent, owing to the force used in extracting it. The hemorrhage was slight, and ceased in a few moments.

DR. S. L. ABBOT reported a case of  
ESOPHAGEAL OBSTRUCTION DUE TO A PIECE OF  
LETTUCE.

Dr. Abbot said that a few years since he had a

<sup>1</sup> See page 109 of the Journal.

call from an elderly gentleman who told him he was unable to swallow, as a piece of lettuce which he had eaten at lunch a few minutes before had stuck in his throat. He declared that nothing else which he had eaten could possibly have caused the obstruction. It gave him no pain. He added that a similar accident had occurred to him once before.

The statement seemed incredible, but when he attempted to drink water it was seen to be immediately regurgitated. Nothing abnormal could be detected in the throat. A probang was easily passed down to the stomach and gave no special kind of resistance in its progress. Immediately afterwards deglutition was easy and painless. It seems probable that a piece of lettuce had got pressed flatwise against the side of the œsophagus, causing a spasm of the tube in its attempt to force it down, which produced the obstruction. Dr. Abbot asked if Dr. Hooper had ever met with a similar case, and he replied he had not.

Dr. S. J. MIXTER reported

**TWO CASES OF EXCISION OF THE THIRD DIVISION OF THE FIFTH PAIR OF NERVES AT THE FORAMEN OVALE FOR NEURALGIA.**

These cases were turned over to me by Dr. Homans at the Massachusetts Hospital, and both had been operated on previously by other methods. One had been trephined, and the other had had the nerve taken out, I think, at the dental foramen. In both these cases the pain returned, and the question of more radical operation came up, and Dr. Homans asked me to operate. The method of operating was to make a curved incision through the skin, and then through the temporal muscle, raising the temporal muscle from the fossa, sawing through the zygoma and gradually working under the base of the skull until the foramen ovale is reached just behind the pterygoid plate. This I did in both cases. The operation is rather long and difficult as the space is rather contracted. I saw Dr. Richardson do one, and I think another since that time. In the first, at any rate, he did not cut through the temporal muscle. It seemed to me that the space acquired for operating was very much greater by cutting through the temporal muscle, and I think in all cases I should do it instead of trying to pull it aside. In any case the amount of room obtained is very small. In both these cases the nerve was found without any great difficulty after the hemorrhage had been checked by pressure. In one case there was considerable atrophy of the nerve on account of previous excision of its terminal branches.

Dr. J. HOMANS presented a report of

**TWO CASES OF PELVIC HÆMATOCELE TREATED BY INCISION PER VAGINAM.<sup>2</sup>**

Dr. CABOT said that he was very much interested in these cases, and thought that they were important at this time, when surgeons are mostly inclined to approach tumors of the pelvis from the abdominal side, in that they showed how safely these blood tumors can be attacked through the vagina and with what good results. He said that in the past summer he had had one such case, in which he had made the opening through the vagina with a perfectly successful result. He drew attention also to the fact that occasionally an aspiration of one of these tumors removing a small

portion of the fluid would be followed by the absorption of the rest of the fluid, and the cure of the patient. He cited a case in support of this view.

Dr. WARREN: I had a case of retro-uterine hæmatocele two years ago, which was opened and drained by the vagina, the cavity being washed out with antiseptic precautions. The patient made a slow, but uneventful recovery. The blood that was removed was in a fluid state and had rather a foul odor. There was some rise of temperature, but no very great consequent disturbance. On first examining this case I found a marked swelling in Douglas's cul-de-sac, and by bi-manual palpation fluctuation could be detected. In cases of sacs containing fluid which are pointing distinctly in Douglas's cul-de-sac I should favor doing this operation. All the cases I have had have done well; and in one or two cases in which recovery has been slow — I am speaking now not of blood collections alone, but cases of abscess — I have found that general measures have been sufficient to set the patient on the right track. I have in mind one case where a pus cavity was opened and drained by tube, and the patient did well at first, but began later to have high evening and low morning temperature and emaciation. The question of laparotomy came up and was decided negatively, and instead she was put in the open air several hours a day, although it was mid-winter, and she began to pick up rapidly. In another patient, on whom the question of laparotomy came up after such an operation was performed by one of my colleagues this fall, the same treatment had the same result.

Dr. MIXTER reported

**A FATAL CASE OF PERINEAL SECTION FOR RUPTURE OF THE URETHRA.**

The patient was a young man who fell from the seat of his bicycle which had the large front wheel and small hind one, striking on the small hind wheel. There was only a little pain, not much swelling and a very slight amount of blood. He was seen by a physician, who advised him to go home, and was seen either that night or the next morning, when it was found that he had retention, and on trying to pass a small rubber catheter only a small amount of blood could be obtained, the catheter apparently not going into the bladder. I was sent for, and not being able to get into the bladder did a perineal section. At that time the perineum was very slightly distended. There was apparently no urine in the tissues, but considerable space was dissected up by a blood clot. The end of the urethra near the bladder was discovered without very great difficulty, and a catheter was tied in. From that time the case progressed without the slightest trouble for nine days. The wound in the perineum closed entirely, and the patient was in first-rate condition. On the ninth day he had a very severe hemorrhage, and I think then that stopped after a little pressure. On the tenth day he had a more severe hemorrhage, and I was sent for. On taking out the catheter — I think it had been changed once — there was a severe hemorrhage, but on putting in a fresh catheter and washing out the bladder the hemorrhage stopped entirely. I then went off on my vacation a day or two afterwards, and was telegraphed for, and saw the boy again about five days after the first hemorrhage. At that time he was feverish, the temperature being over 100°, and there was a distention of the bladder. The physician said he had not been able to get any urine. On pass-

<sup>2</sup> See page 110 of the Journal.

ing the catheter—he had been aspirated over the symphysis and a certain amount of bloody fluid drawn off—it went into the bladder without the slightest trouble, but only brought a small amount of fluid, and a very offensive clot in the eye of the catheter. I found the bladder was nearly filled with a very offensive blood clot, and I gave him a small amount of ether, opened the wound again, which was entirely closed, introduced my finger into the bladder and swept out a large amount of very offensive blood clot, and tied in a large tube. At that time I was able to feel a marked tear apparently on the left side, off to one side of the urethra, much deeper than the original tear in the urethra. This I imagine was the point of the hemorrhage. At any rate it had bled back into the bladder instead of coming out; and this clot had become septic. For a day or two he did well, and although the wound in the bladder gave no trouble, a large tube having been tied in the bladder, he developed septic symptoms, and had tremendous swelling of the parotid and submaxillary glands, and died of septicæmia.

I think the case is an interesting one as showing that we can have a secondary hemorrhage from such a tear so long a time after the original injury, and the production of a very severe form of sepsis by the breaking down of a blood clot. It is practically impossible I think to keep the bladder perfectly aseptic after such an operation. You can keep it nearly so, but with such an enormous blood clot as this it was very easy for it to become septic, and that gave rise to the general symptoms.

DR. CABOT: Is Dr. Mixer sure that this damage in the prostate was not made by the subsequent passage of instruments?

DR. MIXER: I am very positive it was not anything of that sort. It was a deep tear to one side of the prostate unlike anything I have ever seen. We could get no autopsy; and the urethra had entirely healed at the point of the perineal section.

DR. M. H. RICHARDSON read a paper on

#### LAPAROTOMY FOR CYST OF THE PANCREAS.\*

DR. FRIZ: I am much indebted to Dr. Richardson for the opportunities he gave me for seeing this case, and it seemed to me to be a tumor, probably malignant, connected with the stomach or pancreas. In looking up the matter of cysts of the pancreas, however, I find that they are more common than might be inferred from what Dr. Richardson says. I have references to some eighty cases, twenty of which have been operated upon. These tumors have been of all sizes from those holding a few pints to those holding several gallons, and have existed for intervals of a few weeks or several years. They occurred in persons of good general health and in some of poor general health. In one case diabetes was present. In one case laparotomy was performed because there seemed to be acute intestinal obstruction.

With reference to the diagnosis of the nature of these tumors it may be said that in comparatively few instances, and those especially of late years, has an accurate diagnosis been made. The possibilities of making an accurate diagnosis are simply relative. They are based in the first instance upon the determination of the cystic nature of the tumor, and in the second upon the nature of the contents. So far as

the cystic nature of the tumor is concerned in this case, I think no one was able to recognize any fluctuation. Certainly the wall was so tense, and the tumor so deeply seated that a uniform resistance was offered; hence, by palpation, it was not possible to determine whether the tumor was solid or fluid. In a considerable number of cases the tumor is sufficiently large and becomes sufficiently superficial, in the course of time, for fluctuation to be made out with distinctness. In order to determine the nature of the contents of these tumors a test, which has been applied successfully, is exploratory puncture. In most of the cases the fluid which comes is a hemorrhagic fluid. It is a special characteristic of these tumors that the fluid is likely to become hemorrhagic. If, on puncturing, a bloody fluid is obtained it is possible that it may come from a hemorrhagic peritonitis in this region, so that the presence of blood is not of as much importance as considered by many. More stress has been laid upon the resemblance which the fluid presents to the pancreatic secretion, and this resemblance is based upon the properties of this fluid in emulsifying fat, and in saccharifying starches, the former being of more importance. The fluid in pancreatic cysts does not always emulsify fats, and as to saccharifying starches other fluids will do this, so that there are no means by which an absolutely correct diagnosis is to be established except by a surgical operation.

DR. WARREN: I believe I belong to that class of "other surgeons" Dr. Richardson speaks of who made the correct diagnosis. My diagnosis was a snap diagnosis, but was based upon one peculiarity I had impressed upon my mind in looking up the matter in connection with my lectures, and that was the outline of the abdomen, which was characteristic as seen in the books. The outline of his abdomen as he lay upon the table was strikingly like that which illustrates the appearance of abdomens affected with such tumors as this. Of course, that might be the result of the growth of a solid tumor or malignant growth. Whether malignant growths are likely to grow from the retro-peritoneal region in the upper abdominal cavity as in the lower I am not able to say from experience. From my own experience they are in the lower rather than in the upper part of the abdominal cavity. You get these solid growths from the mesentery or retro-peritoneal glands. Those I have seen are generally below or beneath the umbilicus rather than above. At any rate the outline of this case was strikingly similar to that of a diagram I had in my mind.

DR. CUTLER: I saw this case through the kindness of Dr. Richardson, and was very much interested in it. In blowing up the stomach with air, and also filling it with water and blowing up the gut, and filling that with water, it was found that the tumor was distinctly behind both stomach and colon. The position it occupied was such as to suggest some disease in the neighborhood of the pancreas. It seemed to me I got distinct fluctuation in the tumor, and it also seemed so to the house-officers who were present at the second examination; and in view of that sensation and the position of the tumor, it seemed that it must be either a cyst of the pancreas or perhaps one of those soft myxomatous affairs such as Dr. John Homans once removed from a man's abdomen. A thing which occurred to us as a possibility was cyst of the supra-renal capsule or lymph cyst of the omentum. The position of it, however, and the size excluded the latter two, so

\* See page 111 of this Journal.

that it was reduced to the consideration, so far as I was concerned, of entertaining the idea as to whether it was a cyst of the pancreas or an echinococcus cyst or this myxomatous affair, and the position was strongly suggestive of the two first. In the examination of the urine no sugar was found. The faces were examined and no fat found. There were, however, a good many little bundles of muscular fibre, but not many more than would be seen in any ordinary examination. The gastric juice was examined very carefully twice, and the digestion of those articles which are digested in the stomach was carried on so well, and the patient had not shown much of any emaciation or cachexia, so that it was considered that there was no disease in the stomach itself. It seemed to me that one of the two first, either a cyst of the pancreas or an echinococcus cyst, was the most likely; and in the absence of the symptom which is spoken of, the hydatid thrill, which I have never had the opportunity to verify, and the rapidity of the growth, I thought it was most likely to be cyst of the pancreas. As Dr. Fitz has said, quite a number of these cases have been diagnosed, I believe something like thirteen, and these have been operated on, some of them successfully. In all those cases I believe they had an opportunity of examining the fluid before the operation was done, that is, a simple needle was inserted and some of the fluid withdrawn and subjected to examination. As far as the digestion of albuminous matters is concerned, it is, I believe, the case that these fluids quite frequently do not digest food. The emulsifying property is more common, and the change of starch into sugar is still more common. The hæmorrhagic condition which is seen in the fluid from pancreas cyst has been described by quite a number of writers, and is thought to be either a rupture of blood-vessels from the original traumatic condition, or to a digestive action which the pancreatic juice exercises on the broken-up pancreatic organ. This is the first case of the sort I have ever seen, although I think I may have seen one at an earlier date and not recognized it. As far as the size is concerned, no case hitherto has been observed or reported where the tumor was as large as here from the occlusion from a stone. The largest one reported was by Recklinghausen, and the tumor was considerably smaller than this.

**DR. RICHARDSON:** In regard to the diagnosis I think dilatation of the gall-bladder has to be considered in this locality as well as hydatid cyst.

As far as my sense of touch was able to go I could not detect any fluctuation whatever, and I think this case illustrates the value of exploratory laparotomy in obscure cases. I certainly did not expect to accomplish anything by this operation, and others were of the same mind; but bearing in mind that these cysts may rupture into the peritoneal cavity or into other organs with or without hæmorrhage, and that rupture may be fatal, I thought it was very wise to perform the operation. I did not believe that a tense cyst inside of the peritoneum ought to be tapped. I think that is especially true of any cyst which may by extravasation of its contents cause a fatal peritonitis. I think that is true of dilated gall-bladder, cyst of the pancreas or hydronephrosis or any of those cysts that are made up of mucous membrane. In this case the use of the smallest needle was followed by a stream of fluid which came right up out of the wound, the tension on the cyst was so great; therefore I think the

use of the needle in this case would have been very unwise indeed, and I dare say fatal. When diagnosticians differ radically about the diagnosis of the tumor, one looking upon it as a malignant growth, and another as a thing that may be remedied, I believe we ought to perform an exploratory laparotomy.

#### THE NEW YORK NEUROLOGICAL SOCIETY.

MEETING of January 6, 1891.

The President, Dr. L. C. GRAY, in the chair.

#### THERAPEUTIC EXPERIMENTS WITH NITROGEN MONOXIDE.

**DR. W. R. BIRDSALL** related the results of a number of experiments made with this gas, for the purpose of testing its therapeutic value. The speaker had thought it advisable to begin his investigations on the class of cases in which the symptoms, such as pain, spasm and some morbid mental states, called for immediate relief, rather than to watch its effects upon the general course of a chronic disease. In all of the sixteen cases where the gas was administered for the relief of certain symptoms, the action, as a therapeutic agent, had proved valueless. The chief cause of the failure, in the speaker's opinion, was the transient effect of the gas due to its rapid elimination. The extensive series of experiments published by the Odontological Society of Great Britain, showed that the average time required for the production of anaesthesia, was only eighty-one seconds, and the time from the beginning of anaesthesia to recovery of consciousness, but one hundred and fifteen. The various theories of the physiological action of nitrogen monoxide gas were reviewed by the speaker, who then concluded from deductions from other observers' work and his own experiments, that this gas seemed to be an agent which during its inhalation interfered, by displacement, with the normal supply of oxygen to the tissues. And as the cortical functions were the most readily disturbed by imperfect oxygenation, the most striking effect was shown in the marked cerebral disturbance following its administration. That rapid elimination prevented prolonged effects after the supply was cut off, and that the first effect of the gas was on the higher cerebral functions. The long continued and repeated inhalations of the gas, could only be of service when it was desired to deprive the system of oxygen. The inhalation of a gas that produced marked sensations which were sometimes of a startling character, might prove a powerful agent for suggestion, particularly when coupled with verbal suggestion by the physician. In fact, the speaker was inclined to attribute the beneficial effects obtained with hypochondriacal and hysterical patients to this element in the nitrogen monoxide gas. Finally his view, based on physiological and clinical observations, was, that the uses of nitrogen monoxide for medical and surgical purposes, were restricted to its effects as an anæsthetic or as a placebo.

**DR. R. L. PARSONS** said that his experiments with the gas had not given very satisfactory results. He had administered it in a case of melancholia with insomnia. It had produced a feeling of comfort and well-being during the time of inhalation, but the effects were very transient. In another case of opium habit and alcoholism, in which there existed intense muscular

pain and insomnia on withdrawal of the opium, he had given the gas in the hope that it would compensate for the drug. During the administration the patient was fairly well pleased, but had become dissatisfied because the results were not permanent, and were sometimes disagreeable.

DR. W. M. LESZYNSKY said he had taken the opportunity to test this gas in asylum practice for cases of melancholia of mild type, but without any beneficial results. The gas required to be rapidly increased. He hardly thought the cylinder exhibited by the reader of the paper would hold gas enough to do much good.

DR. W. J. MORTON, DR. C. L. DANA, and others spoke to the question, the general opinion seeming to be that nitrogen monoxide was not likely to rank very high as a therapeutic agent.

#### A STUDY OF THE RELATION OF INTERCURRENT ACUTE DISEASES AND SERIOUS INJURIES TO RECOVERY IN TWO THOUSAND CASES OF INSANITY.

DR. W. D. GRANGER read a paper with this title. He thought that the close attention paid to all of the details relating to the life and surrounding comforts of the insane, had much to do in reducing to a minimum the intercurrent of acute diseases in this class of patients. In two thousand cases, extending over an observation period of eight years, the author had never seen acute articular rheumatism, but three cases of pneumonia, three of typhoid fever, and one of diphtheria. Sore throat was abundant, as it was usual in all aggregations of people. Erysipelas appeared from time to time. Epidemics were likely to appear. In spite of a common idea, and the reports of other observers, there was little to be told about the influence of disease on insanity. The simplest common affection from which they suffered was pain, often sudden and severe. Toothache was often added, followed by alveolar abscess. It seldom produced fever. He had never seen more than temporary improvement from pain, though he believed severe toothache might produce recovery. Pain might increase all the mental symptoms, making the mania more active, melancholia deeper, and even dementia more pronounced. Often it had no effect whatever, and often the severest pain seemed to be borne with indifference. Sometimes active mania was quieted, and a rational and self-controlled condition approached. Melancholic patients of a decided type most often bore pain uncomplainingly, but sometimes showed marked mental improvement. In some sore throats, especially the ulcerative varieties, mental improvement of a temporary nature was always expected. The conditions were like those observed in pain, though as a rule more pronounced. In some chronic cases of mania, with confusion and incoherence, the patients talked rationally, while the violent were quieted and often rational. Melancholia was less affected. Dementia was almost always brightened. The expression changed, the mind was more active, the symptoms of venous congestion might partly disappear. In the cases of pneumonia observed, mental improvement occurred in one case only, but in that the change was remarkable; as soon as the disease waned the patient relapsed into his old demented state. In pneumonia the improvement was only temporary. Out of seventy-seven cases of dysentery only four could have been said to have improved mentally. The author thought that his observations should teach

how little truth there was as to the beneficial influence of intercurrent diseases and their effect upon insanity. Considering severe injuries upon insanity, there was much more to be said in favor of the theory. The histories of six cases, in which the patients had jumped from heights of from twenty-five to forty feet from the ground, some sustaining injuries and others not, but with marked mental improvement in all, were fully detailed. To attempt to explain the reason for improvement or recovery after either disease or injury, would be, the speaker said, to involve oneself in an almost hopeless problem, unless further research revealed more definite data upon which to work.

DR. PARSONS said that he had seen a few cases of intercurrent disease, in which the patients previously insane, had become entirely rational, but his experience was the same as that of Dr. Granger, that these results were not permanent. There was no doubt that in some cases of insanity, associated with epilepsy, surgical interference or other traumatism, would retard the explosious for some time. He had seen one case in which counter-irritation by means of a seton was kept up for some years without any recurrence of the fits, upon the healing of the outlet an attack of acute mania had supervened.

DR. E. D. FISHER thought that the idea propounded by Dr. Granger was the correct one. If it were a fact that there was no pathological lesion in mental disease, it could hardly be urged that intercurrent maladies could have any curative effects. But in the functional forms, he could understand how an acute lesion, either from an injury or discharging sore, might have an effect by directing illusions or hallucinations into other channels. But in chronic disease, such as general paresis or mania, or other mental disease with a known pathology, he did not believe the intercurrent diseases would have any lasting effect.

#### A CONTRIBUTION TO THE DIAGNOSIS OF RAYNAUD'S DISEASE.

DR. G. W. JACOBY read a paper on this subject. Although a great deal had been written upon the subject of local asphyxia and symmetrical gangrene since Raynaud first drew attention to this disease, and very many new cases of the affection had been described, the knowledge at the present time of all of its features, except, perhaps, the purely clinical ones, was hardly any more advanced than it was at the time of Raynaud's writing. Etiologically we had in a certain sense, made some progress, for now we realized that other causes than those which Raynaud believed to be the only admissible one, might have a supplementary productive action. As it was recognized that the symptoms of local asphyxia and symmetrical gangrene were often due to unrecognizable states of disordered blood mixture, the author simply touched upon this point. He said that upon the question of anatomical nerve disease as a cause of symmetrical gangrene, there could not be any uncertainty. That the nerves did exert a certain amount of influence upon the production of gangrene, either indirectly, by effecting a contraction of the vessels, and thus suppressing the nutrition of the part (Raynaud), or by producing it independently of the vascular system, could not be denied. According to the assertions of Quensy, section of the nerves was said to produce gangrene of those parts in which they took their course. This assertion had been made repeatedly since then, but the

proofs were wanting on account of the impossibility of completely cutting through all the nerves of a part and leaving the arteries uninjured. On the other hand, a clinical proof of this dependence was found in the fact that gangrene of an extremity occurred after ligation of an artery, more easily if the nerve had been injured than if this was not the case. As stated, in order to make a diagnosis of symmetrical gangrene in Raynaud's sense, we must be able to exclude gross nerve disease. This could not be done in many cases. The class of cases which the speaker dealt with were those cases which came under the caption of gangrene due to pathological changes in the blood-vessels. It was a *sine qua non* for the diagnosis of Raynaud's disease that the lumen of the vessels should be free, and that their walls be found in a healthy condition, so that vascular disease might anatomically be excluded as a causal agency in the production of this affection. If, with this in mind, we reviewed the various cases reported, we would find that although pathological examinations had not been frequently made, still in a number of cases in which this had been done, the condition of the arteries did not fulfil the required obligations. All cases of spontaneous gangrene, symmetrical or unilateral, would require careful attention and examination. In many cases we would be able to discover some local change in the arteries of the affected parts, while in others some general affection of the arterial system would explain the gangrene. Many cases would, however, always remain in which, no matter how careful the examination, no such explanatory conditions could be detected. There were, however, still other cases, which in view of the fact that many of the so-called cases of Raynaud's disease were not symmetrical, and might be ascribed to nerve influence, which were better explained by the assumption of an obliterative endarteritis. It was well known that syphilis produced upon the arteries a periarteritis which gradually encroached upon their entire diameter, finishing as an endarteritis and thus narrowing or even totally obliterating the calibre of the vessel. It was also well known that many cases of spontaneous gangrene, resembling Raynaud's disease in every particular, were often due to such affection of the arteries. What was known about the symptomatology of syphilitic affections of the superficial arteries, as revealed by a study of the few published cases, was as follows: Two phases of the pathological changes found a clinical expression, and obliged us to differentiate a stage of induration, with preservation of the lumen of the artery, and one of obliteration of the artery with all its consequences. In the obliterative stage we had symptoms of ischaemia progressing in extent according to the seat of the affected arteries, and according to the difficulty encountered in the establishment of the collateral circulation; if the terminal arteries of the extremities were affected, the disorders would be very marked, consisting in edema, slight cyanosis, reduction of temperature, and finally, we might also have gangrene of the parts. If, however, small arteries were affected whose collateral ramifications could be replaced, then the symptoms would be transient or entirely wanting. From a consideration of the various data, from the nephritic as well as from the syphilitic cases, we were unavoidably forced to the conclusion that those authors who admitted that an affection of the small arteries, be this arteritis obliterans or other change, did produce a sim-

ilar clinical picture to that found in Raynaud's disease, herein were right, but that these same authors were wrong when they contended that a differential diagnosis between the two affections could always be made. The points which were adduced by the various writers for the purpose of making this differential diagnosis were the following: Gangrene occurred in some cases of Raynaud's disease in places where endarteritis obliterans had thus far never been described; the lesion in many cases of Raynaud's disease was confined to the superficial layers of the cutis, and this never occurred in endarteritis obliterans; the absence of those etiological movements that produced vascular disease, as syphilis, absence of all palpable anatomical changes in the vessels; and, finally, the occurrence of symmetrical gangrene in neuropathic individuals only. That these points were invalid and some of them erroneous, became clear when we considered that it was probable that arteritis obliterans occurred in the vessels of the skin, a condition which had been pointed out by Klotz and Hutchinson. From these facts we were justified in concluding that the differential diagnosis between Raynaud's disease and anatomical disease of the arteries could in many cases not be made intravivam, or, in other words, many of so-called Raynaud's disease were really cases of arteritis.

#### MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH.

The first annual meeting of this association was held in Boston on January 21st. The discussion was mainly confined to two topics — ventilation and rabies; but, before these subjects were brought up, the business usually necessary to such an organization was disposed of.

Soon after the meeting was called to order, the following list of officers was presented and unanimously elected: President, Dr. H. P. Walcott; Vice-Presidents, Dr. S. H. Durgin and Dr. S. W. Abbott; Secretary, Dr. L. F. Woodward; Treasurer, Dr. J. B. Field; Executive Committee, Dr. J. E. Clark of Medford, Dr. W. H. Chapin of Springfield, Dr. W. K. Knowles of Everett, Dr. E. A. Sawyer of Gardner, W. S. French of Newton, Dr. C. H. Morrow of Gloucester, George F. Babbitt of Boston, Dr. M. R. Donovan of Lynn, Dr. G. L. Tobey of Clinton and Prof. L. E. Kieneutt of Worcester.

Then the subject of a legislative committee was brought up, Dr. J. Arthur Gage of Lowell said that better laws were needed on several health matters which he enumerated, but particularly concerning impure milk and tainted meat. He confined his remarks chiefly to milk and Dr. Durgin followed with brief remarks, chiefly on meat.

The motion for a legislative committee was passed, and President Walcott appointed upon it, Dr. S. H. Durgin of Boston, Dr. J. Arthur Gage of Lowell, James C. Coffey of Worcester, Dr. E. R. Cutler of Waltham and Dr. E. A. Sawyer of Gardner.

The matter of placarding houses for infectious diseases was introduced by Dr. J. H. McCollum, of Boston. The doctor explained how the cards were used in this city, and was followed by the representatives of a number of other towns, the consensus of opinion being unanimously in favor of the use of placards. This fact being very evident, Dr. Durgin moved that the practice of placing placards upon houses

in which were cases of infectious diseases be approved by the association, and that it be recommended that these cards remain until the premises are thoroughly disinfected. The motion was unanimously carried.

Dr. A. N. Blodgett, Secretary of the clinical section of the Suffolk Medical Society, was given the floor to invite the members of the health boards to the meeting of the Society in the evening.

Mr. Frederick Tudor read a paper on ventilation. He began by showing the futility of the patent ventilators, and how commissioners and building boards were liable to be deceived by agents who presented only one side of the subject, and that resting on a false basis. He mentioned the hot-water system of heating in the new court-house, and said that everything, even ventilation, had been sacrificed to it. It was the damage resulting from half knowledge of the subject that he emphasized. Too many people thought ventilation was only a matter of an open window or a hole in the ceiling of a room. Fortunately, scientific men had given some definite information on the subject. The demand had been fixed at fifty cubic feet a minute for each individual, which was little enough. The ordinary graded school has a capacity of 10,000 cubic feet, and, with the usual number of scholars, the air must be entirely changed every six minutes to meet the requirements of the standard. The speaker expatiated at some length on the uncertainty and uselessness of what was called natural ventilation, but which is really accidental ventilation, dependent, as it is, on wind and temperature. He then described in detail various artificial methods of ventilation, basing his remarks upon his own experience, and citing as examples, Sever Hall at Harvard College, and the lecture hall of the Institute of Technology, in which he was speaking.

Dr. H. C. Ernst presented a treatise on the subject of rabies, and Pasteur's method of treatment, with the results of his own investigations. Of Pasteur's patients only one per cent. had died, as compared to fifty per cent. previous to the discovery of inoculation.

Dr. Peters followed with some interesting statistics on rabies in Massachusetts, and some new facts of the epidemic that has seemed to attack Massachusetts during the last few years, resulting in fourteen human deaths in 1889, and perhaps more in 1890, although the record for the latter year is not yet obtainable. He advocated the shooting of dogs not muzzled as the best method of getting rid of the disease.

### Recent Literature.

*On Double Consciousness. Experimental Psychological Studies.* By Alfred Binet. Open Court Publishing Company. 1890. 8vo, pp. 93.

This monograph, a collection of recent essays from the pen of a prolific, but always interesting, writer, gives in a small compass the main facts bearing upon double consciousness in its different aspects. One is surprised to find, not only how various are the methods of research and possibilities involved, but also the extended experimental, clinical and laboratory work its investigation call for, and is receiving particularly from the French, chiefly Binet, Janet, Richet, Charcot and the writer. Although pathology has furnished to

psychology the most recent and numerous results, this branch of scientific work — pathological psychology — which is peculiar to France, is practically overlooked in favor of the comparative and physiological aspects as studied in England and Germany.

The experiments are made upon a hysterical subject, one of whose hands, which is completely anæsthetic, is concealed from her view by a screen. Double consciousness is thought to be demonstrated by the fact that a name once written by guiding a pen placed in the insensible hand is, not only repeated by it unaided, but a mistake also in its spelling, intentionally made by the operator, is on a second writing corrected by the patient. The experiment is elaborated to even more remarkable results in the chapters on "The Relations between the Two Consciousnesses," "The Graphic Method and the Doubling of Consciousness," "Suggestion in Double Consciousness," etc. A chapter on "The Hysterical Eye" is striking in its revelations. In the chapter on "Double Consciousness in Health" the writer reaches conclusions which seem hardly warranted by the few insignificant experiments undertaken. The influence of habit in unconscious acts is, moreover, largely ignored, and double consciousness appears as the familiar unconscious cerebration revamped.

While the book is of much interest and perhaps, scientific value, there is an unfortunate absence of detail as to precautions and control of experiments, such as one expects and usually finds in accounts of scientific experiments, and which are all the more necessary, in view of the proclivities of hysterical patients toward deception of themselves and others, as well as the general and quite natural scepticism which exists regarding marvellous and "occult" conditions. Moreover, to instance as corroborative evidence, planchette writing, which has never stood the test of competent investigation, tends to lower the value of the writer's conclusions. We take exception also to his views of the analogy between certain acts due to double consciousness and the impulses of the insane, and very much doubt that a "flood of light" is to be thrown upon the mechanism of insanity, a far different process, by a better knowledge of this dual state as found in a few phenomenal hysterical subjects. We are also given historical instances of dual existence, and if nothing in this line is proven, there is certainly a growing credence among scientific men in the fact of such phenomenal natures. One point at least seems established: the essentially morbid character of all such manifestations.

*Sterility in Women, including its Causation and Treatment.* By ARTHUR W. EDM. M.D., London. Philadelphia: P. Blakiston, Son & Co. 1890.

This small volume of 112 pages while it presents nothing new is a concise and fairly complete treatise on this important subject. The author is judicious in what he recommends in the way of treatment, and his advice may be safely followed. A number of illustrative cases at the end add to the value of the book.

THE Vice-President of the French Society against the Abuse of Tobacco, has made a statement to the Academy of Medicine, that after exhaustive study of the subject, the members of the society have concluded that smoking is the real cause of France's depopulation.

THE BOSTON  
**Medical and Surgical Journal.**

THURSDAY, JANUARY 29, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 233 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,  
233 WASHINGTON STREET, BOSTON, MASS.

THE SEARS LABORATORIES OF THE HARVARD MEDICAL SCHOOL.

It will be gratifying to all friends of a higher medical education to learn that the increased facilities for the study of pathology, pathological anatomy and bacteriology, offered to the Harvard Medical School by Dr. Henry F. Sears, one of its recent graduates, are now in actual use, entire or in part.

It was Dr. Sears's wish that a suitable and convenient building should be erected exclusively for such study with the hope of its promotion. In particular it was desired that investigations relating to the pathology of disease might be fostered among physicians who might lack the needed encouragement and opportunities while engaged in a more or less laborious medical practice.

It has been too much the custom for the physician, in general, to rely upon a more highly trained intelligence for information wholly within his own powers. He is thus led to forget what he has already learned, when, with a little practice, he might readily acquire still further specialized knowledge in subjects with which he is already familiar. But few physicians, after graduation, make even a simple chemical and microscopical examination of a pathological fluid. To correctly classify an anatomical specimen seems often impossible, while the histological diagnosis of a tumor is not even to be thought of. To be able to find tubercle-bacilli in the sputum may be more important than to discover casts in the urine, yet many physicians readily make competent to find each, are unwilling to trust to their own observation.

The Sears laboratories are distinctly intended for the encouragement of such investigations. Physicians who can take but a few weeks, perhaps, only days, or even hours from a more necessary occupation, are at liberty to review what they have already seen and may search for what they wish to see. Some may desire to test the fluid from the stomach of a patient with reference to the quantity of free hydro-chloric acid present, or to its digestive power. Others may wish to learn the characteristics of a pathological fluid, obtained perhaps

from the chest or abdomen, in order that its clinical significance may be more fully determined. The application of so simple a test as the diazo-reaction in typhoid fever, or the effect of chloride of iron in diabetic urine may have been forgotten at a time when the results are most needed, and the pathological laboratory will furnish means for their recognition.

But there are other physicians who desire still further opportunities of study. They may wish to try the various methods of differential staining. They are, perhaps, interested in mitosis, especially in pathological tissues. They would seek for psorosperms or for the fuchsin bodies in cancer. They may desire to follow the course and results of bacteria in the various organs and tissues of the body. Such inquirers will find place and material for their needs.

The other class of workers who have time and talents and a desire for studying unknown problems will be offered all the hospitality the laboratories are able to afford, and it is their work, in particular, which is to make the influence of the laboratory felt beyond its immediate surroundings.

In another column may be found a description of the building, and of its internal arrangements.

ANOTHER ANTIVACCINATION TIRADE.

THERE is a small, but opinionated and blatant minority of scientific men, reinforced by some professional cranks who regularly spread themselves in the newspapers, and by the entire army of antivivisectionists, who have gained notoriety by their vehement opposition to vaccination. There are a few of this guild in the United States, but they have never exerted much influence, while in some parts of Europe they constitute a "League" with its headquarters in Paris, which not only opposes legislative enforcement of vaccination, but is creating a strong sentiment against vaccination among the common people, in some instances, as at Leipsic for a series of years preventing the vaccination and re-vaccination of multitudes of citizens, to the detriment of the city during the small-pox epidemic of 1872, according to Leon Colon.<sup>1</sup>

In Great Britain, the most influential leaders of this movement are, doubtless, Charles Creighton, Edgar Cruikshanks, Alfred Russel Wallace, Allanson Picton, and William J. Collins.

Alfred Russel Wallace (and here we must distinguish between the two aspects of this great man. It is the Wallace of astrological speculation and of spiritualism, rather than the Wallace of science and the coadjutor of Darwin that has espoused the cause of the antivivisectionists), is said "to have applied the tests of genuine scientific scrutiny to Jenner's device, and found it to be, and proved it to be, from the highest official and authentic records, nothing more, nothing less, than sheer delusion."

Edgar Cruikshanks has written a work in two vol-

<sup>1</sup> Traité des Maladies Épidémiques, p. 74.

umes which has been styled "a most important addition to the vast literature of vaccination," "The History and Pathology of Vaccination." His conclusion is "that vaccination is futile, seeing that there is nothing in common between variola and vaccinia."

Collins is chiefly known as an antivaccinationist by his partisanship before the British Royal Commission, whose sessions we have before noticed,<sup>2</sup> and Allanson Pictou, by articles in certain secular English journals and the *Westminster Review*.

Charles Creighton, M.D., is the author of the notoriously one-sided article on vaccination in the "Encyclopædia Britannica." He has still more recently given expression to his views in a long article in a review magazine published in Boston (the *Arena*); title, "Vaccination: a Scientific Inquiry."<sup>3</sup> In brief, his objections are as follows: The vaccine disease has nothing to do with small-pox, being an entirely different disease, and, therefore, cannot protect from small-pox. Cow-pox is a strictly local ailment, whereas small-pox is an eruption of pustules all over the body, attended by fever, and spreading by contagion. Jenner, "a man of quick fancy and very considerable poetic gifts," "took it into his head to become a serious man of science and a practical benefactor of mankind" stumbled at certain analogies and "verbal resemblances," made the greatest scientific blunder of the century, and was not only fooled himself, but has continued to fool a large part of the medical profession. Dr. Creighton marshals statistics to support his contention and repeats his familiar assertions that most, if not all, the cases of vaccine-syphilis are merely bad cases of cow-pox.

In calling attention to this article, we have no intention now to attempt to answer the arguments. The arguments have, in our opinion, been answered by a series of impregnable facts, and every physician has in his own experience and in his library, the means which will enable him to arrive at a calm and rational judgment on this point. The protective efficacy of vaccination has been proved over and over again, on the large scale and in individual instances, and the mass of medical men the world over would as soon think of doubting the Copernican System of Astronomy as doubt that vaccination, if properly performed, with suitable material, and sufficiently often repeated, is a nearly absolute prophylactic against a disease which, a little more than a century ago, caused a mortality of one-tenth of the whole population of Europe, a mortality which, since Jenner's time has been reduced to a fraction of one per cent. This discovery was promulgated by Jenner in 1798, as the fruit of a series of observations and experiments which had occupied his attention for twenty years; and on looking over the original records we are struck by the care and exactness of those experimental observations, and of the tests which were subsequently applied by the various scientific commissions in Great Britain and in other parts of Europe.

<sup>1</sup> *Encyclopædia Britannica*, 9th ed., Vol. 1, p. 200.  
<sup>2</sup> *Am. Med. Rev.*, September, 1889.

We deprecate the publication of such articles as Dr. Creighton's in popular periodicals where they are sure to attract the attention of multitudes of lay readers who will easily thereby get a prejudice against vaccination, perhaps to their serious detriment.

#### A STATE INSTITUTION FOR DRUNKARDS.

At present, in the State of Massachusetts, persons who fall into the hands of the police for being habitual drunkards are for the most part sent to the reformatory, prison or houses of correction, as criminals. A very few are referred to physicians and committing judges, and by them are committed to insane asylums as inebriates or dipsomaniacs. Theoretically, the choice between the two depends in a degree on whether the accused is, apart from being a drunkard, otherwise a criminal. Practically, it may, in certain cases, depend on the influence of friends. About two years ago a bill was passed by the Massachusetts Legislature, laying the foundation for what, as far as we know, is unique as a State institution, if we except the State Asylum for Inebriates, as it was a number of years ago at Binghamton, N. Y. The statute incorporates this institution, giving \$150,000 for 200 beds, and provides that certain habitual drunkards, or, in the words of the law, dipsomaniacs and inebriates, may be committed to it in a manner similar to the present commitment of the insane to insane asylums. It may be considered as between a prison and an asylum. Although legally an asylum, or rather, in the words of the statute, a hospital, it is regarded by the trustees as medically a prison. Any person there confined, except voluntary patients, may be held as long as the trustees think best, within limitations similar to those in force in regard to inebriates in insane asylums.

The trustees have bought a farm near Foxborough, with about thirty acres of good farming land, and have made contracts for the erection of buildings on the cottage plan. In the buildings attempts have been made to avoid herding, and the rooms are all small, for the purpose of separating the patients as much as possible. As much liberty as is compatible with good discipline will be given, and the farm is large enough to give employment to many. It is hoped and expected to have everything ready in eighteen months. The State Board of Lunacy and Charity have the power and will, at their discretion, to transfer patients there who are now in the State asylums as dipsomaniacs. Dr. Marcello Hutchinson, for the past fourteen years assistant physician in the Lunatic Hospital at Taunton, has been made superintendent.

Two of the serious obstacles to the good working of the institution at present seem to be—in the first place, a question as to whether sufficient work can be found to keep the patients busy; and in the second place, a more serious problem, that the bill as it now stands, provides for the commitment of women as well as men. There is no doubt that if women who are habitual drunkards are to be provided for in the

same institution, a much stricter discipline will be necessary, and much less freedom can be allowed.

The experiment of sending drunkards to insane asylums has not been a great success. The number who after leaving have proved themselves permanently reformed has been, as far as can be learned, very small. The promoters of this enterprise hope that a step in the right direction has been taken in founding such an institution. If the results are not what they expect, the buildings, it is said, will be well adapted for use as an insane hospital.

#### MEDICAL NOTES.

**OFFICIAL EXPERIMENTS WITH KOCH'S "LYMPH."** — The President has presented to the Marine-Hospital Bureau two vials of the Koch "lymph" with instructions to make a careful test of its merits. The instructions have been prepared and will be published next week.

**PHILADELPHIA POLICLINIC.** — The new building of the Philadelphia Polyclinic and College for Graduates of Medicine, which has recently been opened, is constructed of brick and terra-cotta, with a frontage on Lombard Street of ninety-six feet and a depth on Naudain Street of 143 feet. In the southwest section is the temporary lecture-room, with a seating capacity of seventy-five, which, upon the completion of the rear portion, will be used for dispensary purposes. The structure has been built to meet the requirement of combining in one institution a hospital and a place for practical teaching.

**A SCHOOL FOR HYGIENE.** — It is stated that Mr. Henry C. Lea, of Philadelphia, has given \$50,000 to the University of Pennsylvania for the erection of a building for hygienic instruction. The plan proposes an institute, where all kinds of food will be analyzed. Apartments are to be provided where tests will be made as to the effect produced by steam heat when applied to mills and dwellings, the evil effects arising from exposing garbage and other offal; and similar questions.

**DR. DUNCAN'S SUCCESSOR.** — On January 8th, Dr. Champneys was elected Physician-Accoucheur and Lecturer on Midwifery at St. Bartholomew's Hospital, and Dr. Walter S. A. Griffith, Assistant Physician-Accoucheur.

**AN IMPERIAL WEDDING PRESENT.** — Dr. F. Brannan, Professor of Surgery in the University of Halle, who in the absence of Professor v. Bergmann performed tracheotomy on the late Emperor Frederick, was married recently, and received on the occasion a patent of hereditary nobility as a wedding present from the reigning kaiser.

**ENGLISH HONORS FOR MEDICAL MEN.** — Her Majesty has been pleased to confer the dignity of a baronetcy of the United Kingdom upon Richard Quain, M.D., F.R.S. Sir Richard Quain is well known as Treasurer of the General Medical Council, and as

Extraordinary Physician to Her Majesty. Professor George Murray Humphry, M.D., F.R.S., Professor of Surgery at Cambridge, has received the honor of knighthood.

**EARLY MARRIAGES IN INDIA.** — The Government of India has decided to legislate on the subject of the age of consent by a simple amendment to the penal code, substituting the age of twelve for that of ten. It has been wisely determined to couple the announcement with the assurance that no interference with social or religious customs affecting early marriage is contemplated.

**HOSPITAL FOUNDED IN A HURRY.** — It is reported that the quickest foundation of a hospital on record is to be credited to Denver. A physician from that city who was in Berlin found that it was impossible, under the German law, to obtain "lymph" for any other than hospital purposes. He did not represent any hospital, but cabled to Denver to establish a hospital at once, which was done under the auspices of the State Medical College, and then he came on to London, where he found enough citizens of Denver to sign his credentials as the authorized representative of the new institution.

**DIPHTHERIA AND CATS.** — The Marine Hospital Bureau publishes the news that diphtheria is reported as having become widely prevalent over the State of Iowa and in several localities epidemic. Two instances have been reported where the disease could be traced to no other source than to cats. The family was so situated that infection was deemed impossible by exposure from other persons. A distant neighbor's cat and the family cat were sick about the premises with all the symptoms of diphtheria, and finally died. Soon after, the children had the disease. In another case, three dead cats were found under the floor. The premises were isolated. It was remembered that prior to the disappearance of the cats they were sick several days. They were removed, and the disease subsided. The sanitary surroundings and water-supply of the premises were unusually good, thus fixing the cats as undoubtedly the source of the disease. The cat will be found a source of this disease to a much greater extent than has been hitherto supposed. The record of investigation shows that not only cats, but chickens, are peculiarly susceptible of this disease.

**SITTING BULL.** — The fact that Sitting Bull was what is called a "medicine man" has been stated in all the notices of his death. Every tribe had, and still has, many medicine men, some of whom are chiefs, all of whom are important persons. The term medicine is a white man's expression which the Indians have adopted. It was applied to the priests of the tribes — for that is what they really are — because the first white men often found them making their incantations at the side of the sick, the wounded, or the dying, where in reality they were propitiating the evil spirits of disease or death. The medicine man is a conjurer, a magician, a dealer in magic, and an intermediary between the men of this world and the spirits of the other. He may know something of the rude phar-

macopœia of his fellows, and may prescribe certain leaves or roots but that is not his business, and such prescriptions are more apt to be offered by the squaws or by any member of the patient's family. The medicine man begins when medicine fails, and continues until death is seen to be certain, when among most of the tribes, the sick or wounded man is abandoned to meet his fate. Those who have followed Sitting Bull's history know that his tribe have long been divided as to his power. One contingent has held that his "medicine" was no good, by which they meant that if he ever had genuine power to converse with spirits that power had left him.

#### BOSTON AND NEW ENGLAND.

**BOSTON STREET DEPARTMENT.**—The Mayor of Boston is said to be having a bill prepared to be presented to the legislature, asking for a consolidation of the street and sewer departments—for so much of the duties of the superintendent of sanitary police as apply to the cleaning of streets; for a repeal of the statute providing that the street commissioners shall be elected by the people, and the passage of an act giving the mayor authority to appoint street commissioners.

**BOSTON LYING-IN HOSPITAL.**—At the recent annual meeting of the Trustees of the Boston Lying-in Hospital it was reported that all but \$3,000, of the \$100,000, which it was decided last spring would be needed for the proposed alterations, had already been subscribed. A large part of the work has already been done, and it is hoped that the building will be completed before next summer. The capacity of the hospital will be nearly doubled; the building will be provided with the most approved appliances for drainage, ventilation, etc.; and will contain an amphitheatre, a series of labor wards, and many other conveniences. We see from the daily press that some members of the community think that the sex of the staff should be changed.

**LUNACY AND CHARITY.**—The annual report of the Massachusetts State Board shows that there were 895 juvenile offenders in custody on the 30th of September. Evidence continues that there is an increase of insanity in this State out of proportion to the increase in the general population. The actual number of cases under observation September 30, 1890, was 5,652. Never have our State lunatic hospitals done so large a year's work. The five lunatic hospitals and Worcester asylum were built to accommodate 2,950 patients; they contain now more than 3,500. Out of 1,663 cases admitted, 192 were said to have become insane through intemperance, while in 121 there was a hereditary predisposition to insanity; 103 persons were committed under the habitual drunkard and dipsomaniac act. The board recommends early legislative action providing for the immediate erection of buildings for the new asylum at Medfield. The board also recommends that such action be taken as will prevent persons from other States and Countries becoming a charge of this State.

**PROPOSED REMOVAL OF THE MAINE MEDICAL COLLEGE TO PORTLAND.**—President Hyde, of Bowdoin College, the professors of the Maine Medical School and representatives of the boards of trustees, overseers and visitors of the Maine Medical Association issue an appeal to citizens of Maine and other friends of the medical school for \$50,000 to build and equip a new medical building in Portland, and an equal sum for laboratory work or endowments, the money to be paid to the president and trustees of Bowdoin College, to be expended at their discretion for uses and purposes of the medical school.

#### NEW YORK.

**MEETING OF THE AQUEDUCT COMMISSION.**—At a meeting of the Aqueduct Commission held January 22d, it was decided to have constructed a new large dam on the Croton River at Cornell's. The estimated cost of this immense work is \$4,750,000, and it will take several years to build; but the capacity of the reservoir will be raised to 30,000,000,000 gallons.

**AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.**—The American Electro-Therapeutic Association was organized at the New York Academy of Medicine on January 22, 1891. The officers elected were as follows: President, Dr. G. Betton Massey, of Philadelphia; Vice-Presidents, Drs. W. J. Morton and A. H. Goelet, of New York; Secretary, Dr. William H. Walling, of Philadelphia; Treasurer, Dr. George H. Robé, of Baltimore; Executive Committee, Drs. H. R. Bigelow, of Philadelphia; F. H. Martin, of Chicago; William H. Hutchinson, of Providence, R. I.; and B. D. Palmer, of Cincinnati.

**ANNUAL REPORT OF THE DEMILT DISPENSARY.**—The annual report of the Demilt Dispensary shows that during the past year 33,778 patients were treated by its physicians, 28,320 at the dispensary, and 5,458 at their own homes. There were in all nearly 75,000 medical consultations, and 65,891 prescriptions were put up. In rendering the work of the dispensary more complete the female visitor of the Society for Ethical Culture made 2,722 visits to the homes of the patients, distributing clothing and sick-room delicacies and comforts, and the Diet Kitchen distributed large quantities of milk, beef-tea and other supplies on the requisition of the visiting physicians. There are now fifty-six on the medical staff of the institution.

**ACQUITTALS ON THE GROUND OF INSANITY.**—A bill is about to be introduced in the legislature providing that whenever, upon the trial of any indictment for any capital offense, the jury shall acquit the defendant on the ground of insanity, such insanity shall be presumed to continue, and the court in which such acquittal shall be had shall make an order that the person so acquitted shall be confined in the State lunatic asylum for a period of not less than ten nor more than twenty years, and until it shall be proved in the manner provided by law that the defendant has been restored to sanity. The governor is given pardoning power in such cases.

## Miscellany.

### A DESCRIPTION OF THE SEARS LABORATORIES OF THE HARVARD MEDICAL SCHOOL.

THE building for these laboratories was designed by William Whitney Lewis, of Boston, who has very satisfactorily carried out the demands made upon him. It was desired that as much room and light should be obtained as the gift, thirty-five thousand dollars, would permit; and it was agreed that the finishing should be of the simplest possible nature. The length of the building, which is of brick, is eighty-eight feet, the width thirty feet. It consists of three stories and a basement. It faces to the north, and its length is equally divided into window-space and wall-space. The upper story is also lighted by a large window in the roof. Each floor is divided by transverse wooden partitions, and the rooms thus separated are lighted from the south as well as from the north. The brick walls are left bare, the floors are of heavy timber supported on transverse beams which span the space between the walls. The rooms are heated by the indirect method. Each stack of steam-pipes, encased in a galvanized iron box, stands against the wall, and receives its independent supply of fresh air through an opening in the wall just behind the stack. A ventilating chimney on the south side of the building provides an exit for the air. An iron staircase, encased in a brick well, furnished with tinued doors, between the medical school building and the Sears building, furnishes the means of reaching the laboratories.

The first floor is on a level with the students' study, through which general admission to the Sears building takes place. The second floor is on a level with the physiological and chemical laboratories, and may be entered directly from the former. The third floor is a few feet below that of the museum, which may be entered by a way beneath the seats of the amphitheatre. This freedom of communication makes the Sears building a part of the medical school building, with which it is immediately connected.

The basement is divided into rooms for the care of animals, a cold room for the bacteriological laboratory, and a room for storage. A lift ascends in the well to the top of the building from this floor, and a doorway opens from the well into the basement of the medical school building.

The first floor is a bacteriological laboratory, and is under the charge of Dr. H. C. Ernst. It is intended for the use of advanced students in this science, the undergraduates being provided for in the bacteriological laboratory on the same floor in the main building. The new laboratory contains several small rooms in each of which one or two workers may carry on investigations with the least possible interference. One room is provided for the sterilizing ovens, another for the storage of cultures, while the constant temperature apparatus is under observation in the largest room from which the others open. An operating room is provided, also a chemical laboratory for the study of ptomaines, and a special room for the cleansing and storage of glass-ware.

The second floor is divided into two large laboratories, both under the immediate charge of Dr. W. F. Whitney, and are intended for the use of special stu-

dents in pathology and pathological anatomy. The laboratory first entered has wall-tables for twelve persons, and opportunities for as many more can be furnished, if needed. This room contains a chemical hood, a hooded-sink and a large central table. The latter and the wall-tables are furnished with drawers and lockers. A doorway leads into the second laboratory, which is of equal size, and is occupied by Drs. Whitney, Gannett and Sears. It contains the library of the laboratory, the nucleus of which was given by Miss Lucy Ellis from the library of her brother, the late Dr. Calvin Ellis, whose interest in the school where he was for so many years a professor, and especially in the study of pathological anatomy, was most devoted. Dr. Sears has added his own medical library to the Ellis collection, and it is intended that an efficient working-library shall be one of the features of the laboratory. Two small adjoining rooms are fitted up, one for an assistant, the other as a work-room in which the coarser kinds of mechanical work are to be carried on.

The third story is open throughout the greater part of its length, being designed for the use of the entire class, a hundred, more or less, of undergraduate students in pathology and pathological anatomy. Demonstrations are held in this room twice a week. Practical exercises in pathological histology are given on two other days. Special instruction is also given here to classes of fourth-year students and graduates who wish to continue their study of pathological anatomy without devoting a considerable amount of time to the subject. Students are at liberty to use this room at any time.

Connected with this class-room is one extending the width of the building and intended for photographic purposes. The north windows are sheets of plate-glass, and there is a vertical window in the roof. Three dark rooms are partitioned off, in which every convenience is to be had for the treatment of negatives.

It will be seen from this brief statement that the Sears Laboratories offer facilities for more or less advanced study in pathology, pathological anatomy and in bacteriology. Not only is ample provision made for the beginner, but it is intended also to offer every encouragement to those who desire to know something more than everybody knows. In particular it is hoped that special workers may be attracted to the laboratory, and by their investigations help to extend its efforts in promoting exactness in the study of disease.

### A SIMPLE MEANS OF JUGULATING CEPHALALGIA AND FACIAL NEURALGIA.

NAEGELI<sup>1</sup> reports that he has repeatedly cut short different forms of cephalalgia and odontalgia by raising the hyoid bone, or, which amounts to the same thing, the larynx, and keeping it raised for sixty or seventy seconds. Several *séances* are sometimes necessary, often but one, to obtain complete control over the various neuroses of the cranial nerves, and the cephalalgia resulting from excessive drinking. For the explanation of this phenomenon the author refers the reader to the anatomist or the physiologist.

<sup>1</sup> Cor. Bl. für Schweiz. Aerzte, June 15, and Satellite, December, 1890.

## INJECTIONS OF PYOKTANIN IN CYSTITIS.

DR. LEON NENCKI,<sup>1</sup> of Warsaw, reports four cases of exceedingly obstinate chronic cystitis, three of gonorrhoeal, one of rheumatic origin, in which, after ordinary measures had completely failed, the injection of a 1 in 1000 and 1 in 500 solution of blue pyoktanin, repeated twice daily, was followed by cure in from ten to fourteen days. In every one of the cases, a very marked amelioration with decrease in turbidity of the urine and disappearance of alkaline reaction and pain, etc., took place in a couple of days after the beginning of the treatment.

## THERMO-PALPATION.

As an aid to physical diagnosis Benczur and Jonas<sup>2</sup> call attention to the differences in temperature of the skin of the thorax and abdomen corresponding to the underlying organs. With a little practice, by passing the hand lightly over the skin the authors were able to map out the areas of splenic and cardiac dulness, the upper line of pleuritic effusions, etc. The region of dulness is described as being always cooler to the touch, whereas over organs containing air, the skin is relatively warm. The results were confirmed by specially constructed thermometers.

## PERIODICITY OF PHYSIOLOGICAL FUNCTIONS IN WOMEN.

PROFESSOR OTT<sup>3</sup> has recently made a study of the laws of periodicity of the physiological function in the female organism. He made his researches through the careful observation of fifty-seven women during sixty-eight menstrual periods; these women were all observed daily by Professor Ott. The subjects of special investigation were: radiation of heat, muscular force, respiratory capacity and force of pulmonary expiration, and, lastly, the patella reflex. The result proved that the energy of the functions of the female organism increases before the beginning of the menstrual period, and diminishes immediately before or at the appearance of catamenial hemorrhage. Abundant researches have shown that the pulse, temperature, and blood-pressure in little girls between eight and thirteen, and in women between fifty-eight and eighty, do not undergo periodical oscillations such as are observed during the age of sexual activity.

## TREATMENT OF EPILEPSY BY THE COMBINED USAGE OF ANTIPIRYNE AND BROMIDE OF AMMONIUM.

AN English physician, Charles Potts, reports the success in treatment of forty-three cases of confirmed epilepsy by the combined usage of antipyrine and bromide of ammonium, according to the method first suggested by Dr. H. C. Wood.

Three times a day five or six grains of antipyrine are administered, and from ten to twenty grains of bromide of ammonium in solution. Under the influence of this treatment, the epileptic seizures become less and less frequent and severe, and in many cases disappear altogether.

## SILK RIBBONS FOR DRAINAGE.

A SYSTEM of drainage which has been in use in Nussbaum's clinic for some time, is described by Fessler.<sup>4</sup> Common protective silk is cut into ribbons of from a third of an inch to two inches in breadth, and kept in a 1 to 1000 solution of corrosive sublimate. These strips are laid in the wound so that one end protrudes a short distance, and is covered by the dressing. When the dressing is changed the silk is pulled out a short distance, and the outer end cut off. Drainage by this method is said to be perfect, the smooth surface of the silk aiding the flow without in the least irritating the wound. The advantages over a stiff drainage-tube are many. The ribbons are easily rendered aseptic, dressings are easily applied over them, and fistulae never remain after the drainage is removed.

## STERILIZATION OF RUBBER CATHETERS.

DR. ALAPY<sup>5</sup> describes a new method of effecting the sterilization of these instruments, which possesses, he asserts, the merit of being very effective, easy to carry out, and harmless to the instruments. After drawing attention to the effects of various antiseptics, such as carbolic acid, sublimate, etc., and heat as ordinarily applied, he goes on to describe his own plan, which practically consists in wrapping up the instruments, not more than three or four in a packet, in ordinary blotting paper, the ends of which are just twisted up. These packets are then placed in glass tubes, the mouths of which are sealed with a plug of cotton wool. The glass tubes are exposed for half an hour to ordinary steam, that is to a temperature of 100° C. The packets of blotting paper are then removed, and kept in a drawer or box till they are required for use. They remain sterilized for any length of time, provided the paper is not opened, as is shown by the fact that they are incapable of infecting either sterilized bouillon or sterilized urine.

## SUBCUTANEOUS INJECTIONS OF ETHER IN HEPATIC COLIC.

KUMS, a few months ago, published a paper describing the successful results of this method of treatment in various forms of neuralgia. He has since found,<sup>6</sup> in two cases, that subcutaneous injections of ether are most effectual in relieving hepatic colic. In one of these cases, two injections over the region of the liver, one administered at mid-day and the other in the evening, and repeated next day, caused great relief. The symptoms of jaundice, however, persisted, and fifteen days later a fresh attack of hepatic colic occurred. Under the influence of fresh injections of ether, the pain entirely ceased, the jaundice disappeared, and no further symptoms had occurred two months later. In the other case, the treatment was even more quickly successful. Injections, administered morning and evening for two days, were quickly followed by complete disappearance of pain and of jaundice. Kums recommends the use of Hoffman's anodyne (the *spt. etheris B.P.*, a mixture of sulphuric ether, and alcohol in

<sup>1</sup> Münch. med. Wochenschr., No. 21, 1890.

<sup>2</sup> *Annal. des Mal. des Organes Genito Urin.*, July, 1890, and *Brit. Med. Jour.*, November 8, 1890.

<sup>3</sup> *La Semaine Medicale*, October 8, 1890.

<sup>4</sup> *Archiv. f. Klin. Med.*, 1890, 1.

<sup>5</sup> *Brit. Med. Jour.*, 1890, 1, 4, 16, 18, 19.

<sup>6</sup> *Brit. Med. Jour.*, December 6th.

equal parts, instead of pure ether, as he believes that it is more easily absorbed by organic tissues containing water when mixed with alcohol, than when injected alone, and that it therefore acts more rapidly.

### THE BARKING COUGH OF PUBERTY.

SIR ANDREW CLARK calls attention to what he describes as the barking cough of puberty (cynobex hebetis), previously alluded to by him, and somewhat differently by Sir Morrell Mackenzie. This peculiar cough occurs generally in nervous subjects, about the time of puberty, and more commonly in girls than in boys. It is not an ordinary nervous cough, not the ordinary cough of local irritation, of related pathological changes, of reflex action, of pneumogastric trouble, or of mere hysterical disorder, but possessed of certain distinguishing characteristics, existing always in the same general environment, and occurring almost exclusively within the range of those physical and psychological changes which mark the advent of puberty and accompany the final evolution of sex. It has a well-defined individuality of its own, and claims the right of separate consideration and naming. A case is given: A boy, aged fourteen, was the subject, for several months, of an incoercible convulsive cough. The parents belonged to a nervous family; he was himself nervous, and whilst under examination was odd in movements and restless in manner. Careful examination brought to light no sign of special structural disease. The paroxysm consisted of a succession of loud, dry, clanging, convulsive coughs, varying in intensity and duration, broken into irregular bars or phrases, and resembling at one time the barking, and at another the howling, of a dog. During the continuance of the paroxysm the patient appeared to be much distressed: his face was swollen and faintly livid, the eye-balls became prominent and congested. At the close of the paroxysm, which lasted over a minute, the patient appeared to be a little dazed, and was somewhat giddy. Recovering himself in a few minutes, he passed a quantity of limpid urine.

Although generally seen in nervous persons, it may occur in those that are not. No local adequate changes are to be found in the pharynx, in the larynx, or in the lungs, the cough and other disturbances of the respiratory movements are rhythmic and paroxysmal, no structural degenerations follow in the wake of the malady, and it disappears with, or shortly after, the complete evolution of sex. We cannot justly doubt that this convulsion or barking cough of puberty is a malady of nervous origin, character, course, and issues.

Concerning the prognosis of the malady, all the cases as far as known, although usually tedious and always somewhat prolonged, have ended eventually in complete recovery.

The patients are generally plainly overfed. Improvement has almost invariably followed the enforcement of a simple, but liberal, dietary arranged into three, or at most four, meals a day, abstinence from alcohol, cold or tepid sponging, warm, but not too warm, clothing, active outdoor exercise, early hours, and general discipline.

Of local applications to the interior of the throat,

only two have done good service; the first is glycerine of borax with oxychloride of bismuth and morphine, and the second is the same combination with the substitution of cocaine (10 per cent.) for morphine.

Among the internal remedies there are also two; the one is a syrup of the bromide of quinine and iron, with small doses of arsenic, and the other is a pill of reduced iron, valerianate of zinc, belladonna, and nuxvomica.

### PRESCRIPTIONS.

SACCHARIN. — A solution of saccharin corresponding to simple syrup may be made as follows: <sup>1</sup>

R Saccharin . . . . . 2 grammes.  
Aque destil. . . . . 250 grammes. M.

From the same saccharin syrups may be made, as

R Tinct. aurantii amari . . . . . 10 parts.  
Sol. saccharin simp. . . . . 70 parts. M.

LACTIC ACID IN INFANTILE DIARRHŒA. — Thomas <sup>2</sup> uses the following not only in the green diarrhœa of infants, but also in cases of gastro-intestinal dyspepsia without fever.

R Acid lactic. . . . . 2 parts.  
Syrup. simp. . . . . 15 parts.  
Aque . . . . . 85 parts. M.

One teaspoonful should be given from a quarter to half an hour after each meal; if given sooner the acid is liable to cause rapid coagulation of the milk in large solid curds. In mild cases five or six doses a day are sufficient, but in acute cases it should be given much more frequently.

TERPINE HYDRATE IN WHOOPING-COUGH. — Of all the new remedies, Talamon <sup>3</sup> would give the preference to terpine, especially if the pertussis is accompanied by an abundant catarrhal secretion. The following formula is recommended:

R Terpine . . . . . gr. xv to xxv.  
Antipyrin . . . . . gr. xv.  
Syrup of orange peel . . . . . 3 jss.  
Linden water (or nuxlage) . . . . . 3 ii. M.

Dose, from one to two teaspoonfuls several times a day to a child of from one to four years of age.

## RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, JANUARY 17, 1891.

Cities.	Estimated population for 1890.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from				
				Infectious diseases.	Acute lung diseases.	Typhoid fever.	Diphtheria and croup.	Scarlet fever.
New York	1,622,237	78	285	18.08	27.84	.48	6.56	3.52
Chicago	1,129,000	—	—	—	—	—	—	—
Philadelphia	1,064,277	433	126	9.66	10.58	2.07	5.29	1.38

Deaths reported 2,432; under five years of age 823; principal infectious diseases 426; small-pox, measles, diphtheria, croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 233; acute lung diseases 426; consumption 296; diphtheria and croup 143; scarlet fever 48; typhoid fever 18; measles 29; diarrheal diseases 21; whooping-cough 18; cerebro-spinal meningitis 10; erysipelas 10; malarial fever 6.

From diarrheal diseases New York 9, Philadelphia and St. Louis 3 each, Washington 2, Brooklyn, Boston, Nashville and Newton 1 each. From whooping-cough New York 12, Brooklyn 2, Philadelphia, St. Louis, Boston and Lowell 1 each. From measles New York 18, Brooklyn 4, Boston 3, Nashville and Fall River 2 each. From cerebro-spinal meningitis New York and Quincy 2 each, Brooklyn, Boston, Washington, Lowell, Lynn and Salem 1 each. From erysipelas New York 3, St. Louis and Boston 2 each, Brooklyn, Nashville and New Bedford 1 each. From malarial fever New York 3, Brooklyn 2, Cambridge 1.

In the twenty-eight great towns of England and Wales with an estimated population of 10,010,424, for the week ending January 10th, the death-rate was 28.1. Deaths reported 5,394; acute diseases of the respiratory organs (diphtheria) 291, measles 183, whooping-cough 131, scarlet fever 51, diphtheria 46, diarrhoea 40, fever 28.

The death-rates ranged from 15.7 in Derby to 39.8 in Portsmouth, Birmingham 27.1, Bradford 22.7, Hull 20.2, Leeds 28.6, Leicester 22.4, Liverpool 27.9, London 29.1, Nottingham 18.8, Sheffield 25.7.

In Edinburgh 30.1, Glasgow 30.2, Dublin 26.0.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 17, 1891, TO JANUARY 24, 1891.

By direction of the Secretary of War, Captain FRANK J. L. is assistant surgeon, relieved from temporary duty at Ridge Agency, South Dakota, to take effect when his services can be required by the commanding officer of the troops there stationed, and will then return to New York City and resume his office of assistant surgeon, S. O. 17, Par. 9, A. G. O., Washington, January 17, 1891.

By direction of the Secretary of War, Captain EDWIN F. GAYLORD, assistant surgeon, is relieved from duty at Pine

Ridge Agency, South Dakota, and will proceed, without delay, to Fort Riley, Kansas, and report for temporary duty to the commanding officer of that post. S. O. 17, Par. 10, A. G. O., Washington, January 21, 1891.

## OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 24, 1891.

REMIUS C. PERSONS, surgeon, ordered to the U. S. S. "Concord," February 10, 1891.

## SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held, at 19 Boylston Place, on Monday evening, February 2d, at eight o'clock.

Readers: Dr. J. B. Swift, "Some Observations on Anteflexion of the Uterus"; Dr. J. Orne Green, "A Case of Abscess of the Brain with Chronic Middle Ear Disease."

T. F. SHERMAN, M.D., Secretary.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a meeting of this Section, at 19 Boylston Place, on Wednesday evening, February 4th, at eight o'clock.

Dr. Paul Thorndike will read a paper on "Kraske's Resection of the Rectum for Malignant Disease." Dr. W. J. Otis will give a demonstration of his method of High Rectal Inspection; in connection with which Dr. E. L. Parks will show Leiter's Latest Electric Lamp; Dr. F. S. Watson will show a case of Skin-Grafting by Thiersch's Method.

GEORGE H. MONKS, M.D., Secretary.

## DEATHS.

A. H. Chessmore, M.D., President of the Vermont State Board of Health, Surgeon of the Fifth Vermont Regiment, died, January 27th, aged fifty.

Piercen Rector, M.D., of Jersey City, N. J., died, January 21st, aged fifty-two.

Dr. Friedrich Wiegner, Professor of Internal Pathology in the University of Strassburg, died recently at the age of seventy.

George Gulliver, M.B., F.R.C.P., senior assistant physician, and demonstrator of morbid anatomy at St. Thomas's Hospital, and physician to the London Fever Hospital, died, January 11th, aged thirty-nine.

## BOOKS AND PAMPHLETS RECEIVED.

The Physician's Hand-book for 1891. New York: G. P. Putnam's Sons.

Thirty-seventh Annual Report of the Trustees of the State Almshouse at Tewksbury.

Transactions of the Medical Society of the State of West Virginia. Twenty-third Annual Session. 1890.

Use and Abuse of the Obstetrical Forceps. By Eugene Prosper Bernarly, M.D., of Philadelphia. Reprint. 1890.

Forty-third Annual Report of the Trustees of the Massachusetts School for the Feeble-Minded, for the Year ending September 30, 1890.

Two Cases of Prostatectomy. By J. William White, M.D., Professor of Clinical Surgery in the University of Pennsylvania, etc. Reprint. 1890.

Medico-Chirurgical Transactions. The Royal Medical and Chirurgical Society of London. Volume LXXIII. London: Longmans, Green & Co. 1890.

A Practical Treatise on Fractures and Dislocations. By Frank Hastings Hamilton, A.M., M.D., LL.D. Eighth edition, revised and edited by Stephen Smith, A.M., M.D. Philadelphia: Lea Brothers & Co. 1891.

Structure of the Central Nervous System. Twelve Lectures for Physicians and Students. By Dr. Ludwig Edinger, Frankfurt. Second edition. Translated by Willis Hall Vitum, M.D. Edited by C. Eugene Riggs, A.M., M.D. Philadelphia: F. A. Davis. 1890.

An Illustrated Encyclopaedic Medical Dictionary, being a Dictionary of the Technical Terms used by Writers on Medicine and the Collateral Sciences, in the Latin, English, French and German Languages. By Frank P. Foster, M.D. New York: D. Appleton & Company. 1890.

Cranietomy for Microcephalus. The Later History of a Case of Excision of the Head-Centre for Epilepsy. A Clinical Lecture delivered at the Jefferson Medical College Hospital, November 19, 1890. By W. W. Keen, M.D., Professor of the Principles of Surgery. Reprint. 1890.

## Address.

EARLY DIAGNOSIS OF SOME SERIOUS DISEASES OF THE NERVOUS SYSTEM; ITS IMPORTANCE AND FEASIBILITY.<sup>1</sup>

BY E. C. SEGUIN, M.D., PROVIDENCE, R. I.

## II. DEMENTIA-PARALYTICA.

THIS, the passive form of general paresis, so-called, is often seen by the general practitioner at its earlier stages, and the gravity of the symptoms is almost never appreciated. Even by neurologists the diagnosis of nervous prostration or cerebral fatigue is often made and a delusive prognosis given. Rest and change are advised, when an active medication and seclusion from excitement should be prescribed.

The symptoms by which an early diagnosis can be made are as follows, in order of importance:

(1) A change in the patient's moral character; ethical changes. Ethical development is the last and highest phase of action or function of the cerebrum in mammals, and more strikingly in man; it is the least instinctive or organic function, a sort of delicate efflorescence; and, consequently, it is not surprising that it should be the first to retrograde when the cerebrum is undergoing widespread degeneration of slight degree. The alteration, allow me to repeat, is a positive *change*, not an accentuation to a morbid degree of the patient's previous faults of character, as is observed in various forms of insanity. Diminished regard for decorum, slovenly habits, in dress and at table, slight deviations from truthfulness, an inclination for, or relish for, ribald or obscene jokes, actual indecency in language and acts, indulgence in stimulants, lascivious familiarities and visits to houses of prostitution, etc., in a man who previously never lapsed in such matters, should always cause the greatest concern and lead to a suspicion of beginning diffused encephalitis.

Irritability or abnormal anger might be included in this list, but this increased reaction to external stimuli is a symptom more characteristic of cerebral neurasthenia, hysteria, etc., and seldom means a change in character. Indeed, in my experience, good nature and abnormal pliability are more frequent than irritability in dementia. The same remarks apply to the abnormal emotions shown by victims of this disease: they laugh or cry "hysterically" on the slightest provocation. This state, however, only means that we have an abnormally sensitive brain and diminished self-restraint before us—conditions fully as frequent in simple cerebral neurasthenia as in dementia-paralytica.

Not rarely these symptoms, though appearing very early, are not known to the physician because the patient cannot tell of them, and his relatives are ashamed to reveal them. They must be sought for; consequently, although these ethical symptoms are of great importance, they cannot be designated as striking or as leading symptoms, except to the family physician, who, of course, has peculiar opportunities for noting these changes, even before the family is alarmed.<sup>2</sup>

Often it is believed by laymen and physicians that the alcoholic and sexual irregularities of the patient are causes of subsequent symptoms, but this is, most authorities agree, an erroneous and dangerous view.

<sup>1</sup> Delivered before the Providence Medical Association, December 1, 1896. Continued from Vol. CXXIII, page 608, of the Journal.

<sup>2</sup> I have sometimes first heard of these symptoms some time after the consultation, from associates and friends of the patient; the family having carefully concealed them.

Doubtless minute changes in the brain precede the ethical degradation.

(2) Mental dulness and inaccuracy. The patient often complains of these himself; he is becoming "lazy," mental exertion is onerous; he feels dull and even drowsy during business hours; he is conscious of doing everything slowly and laboriously. He notes mistakes in his calculations, failures to keep appointment, and other evidences of failing memory and impaired power of attention. Many cases—those in which a slight degree of exaltation appears early—are unaware of these faults and energetically deny them. Yet it is astonishing how long professional or old habitual acts continue to be performed with tolerable exactness, even after many symptoms have appeared. Such mental operations as have by long practice become almost automatic or semi-instinctive resist the disease remarkably.<sup>3</sup>

(3) Motor disturbances. These are often the first which are complained of by the patient. Difficulty and slowness of articulation; awkwardness of the fingers for delicate movements; impaired handwriting; visible tremor; a general loss of muscular force are often perfectly evident to the patient in those cases where exaltation has not set in. I have notes of several cases in which the patient came to me spontaneously for difficult articulation (this appearing to him the only symptom).

In very rare cases impaired articulation with slight tremor of the hands, are really the first symptoms. I have notes of one such case, in which I made the diagnosis at that stage; the patient dying in Germany several years later with all the symptoms present.

As tremor underlies the faulty speech (or dysarthria) and the awkwardness, allow me to speak of it at some length. Different cases present tremors, which I am in the habit of classifying as coarse and fine. Sometimes it requires the closest scrutiny to detect them, or they may be almost choreic in form. Always these tremors appear only on exertion; they are not, strictly speaking, fibrillary contractions, nor are they at all like the rhythmical or quasi-rhythmical movements of paralysis agitans, senile or alcoholic trembling. Consequently you will have to seek for this symptom by bidding the patient to do certain things. "Sitting quietly he appears free from tremors; bid him frown, and the muscles of the upper part of the face show tremulous action; bid him show his gums, the tremor appears in all the lower facial muscles; bid him protrude the tongue, and that organ appears filled with fine tremulous contractions, or is agitated as a whole by coarser tremors; make the patient hold out his hands, and various degrees of non-rhythmical tremor are apparent to your eye or to your fingers (if you hold his fingers within yours). Tell him to speak, and the aerial waves are broken by the irregular muscular contraction, producing various forms of faulty articulation. Emotion, which in almost all persons is accompanied by unconscious muscular movements in various parts, also brings out the tremors. At once when the patient begins to tell you his ailments or replies to your questions, the faulty speech reveals the tremors, and to the experienced ear foretells the man's doom.

<sup>3</sup> I have known of physicians who attended to ordinary practice fairly well (but were suspected of drinking by their clients) for a long time after the diagnosis was clear; and two years ago I made a diagnosis of dementia-paralytica in a popular actor who "starred" about the country with diminishing success for several months afterward.

For, gentlemen, if there is a pathognomonic symptom in all semeiology, it is the peculiar faulty speech of the early stage of non-delirious dementia-paralytica. It is as valuable for the diagnosis of this disease as fulgurating pains are for that of tabes. Yet a similar speech (or at least one that seems like it), is met with once in a while in a generally tremulous patient who has not cortical degeneration. So rare is this that I have record of but one example; so that the value of the symptom remains very great.

The fundamental character of the speech in paresis (to use the ordinary short name for the disease) is non-rhythmic vibration. This leads to a jerky irregular utterance, and a still further degree of muscular tremor (or as some wrongly say of incoordination), causes the hardly perceptible sounding or the omission of syllables in long words. It is a mistake, in my opinion, to consider this omission of syllables as the characteristic fault. It is not present at the early period when I would wish my *confères* to diagnose the disease. It is almost impossible to describe by words the characteristics of speech so altered. Last spring I made experiments with the phonograph, hoping to obtain cylinders which might be used to demonstrate to students the faulty speech of this disease, and others, but found that the instrument was not yet delicate enough for that purpose. It requires a good speaker to make a useful record on the machines now in market.

Allow me to repeat that the speech of paresis is tremulous, jerky yet often slow; some syllables are spoiled and some are omitted from long words. No other disease causes this.

(1) Pupillary symptoms. Here we see an indication of the close relationship of posterior spinal sclerosis and dementia-paralytica. In point of fact one disease is sometimes complicated by the other and *vice versa*. The pupillary symptoms to be observed are:

Contraction, with loss of passive dilation in the dark. The pupils are often so small as to deserve the appellation of pin-head pupils shading the eyes or placing the patient in a dark room causes no expansion. They are in a state of spasm as German writers call it.

Inequality is very frequent; it may be difficult to detect, but few cases in my experience have not presented this peculiarity.

In some rare cases (probably truly of syphilitic origin), the pupils are motionless and unequal but wide. Thus we may say that in dementia-paralytica and in posterior spinal sclerosis we meet with unequal, Argyll-Robertson pupils; much more often small in the former disease. Atrophy of the optic nerves is rare.

(5) The patient's manner is very suggestive, quite early in the disease. The patient seems confused in taking a chair, or trying to leave the room; he looks at various objects in your office regardless of the fact that you are questioning him; he looks from his friends to you in a stupid, helpless manner; and tolerates that they answer for him. Frequently he interrupts his friends to deny the symptoms they relate. When once seen, it is a behavior never to be forgotten.

As a part of this confusion some patients appropriate objects which do not belong to them, under the idea

that they do. This leads to arrests for shop-lifting, etc.

The psychological mechanism of these symptoms is that the patient's perceptions are fleeting and imperfect; his will power diminished; his power of attention impaired; he labors under a sense of unreality and uncertainty.

(6) Varying degrees of exaltation, or morbid optimism. With slow, tremulous, broken speech the unfortunate patient will tell you that he "feels first-rate," "was never better in my life," etc., in shocking contrast to the obvious mental and physical decay. In some cases pretty early, in others later this exaltation grows to extraordinary proportions; the patient claims herculean strength, unmeasured wealth, limitless sexual power (when impotent), supernatural powers, etc. This constitutes the "exalted delirium" with which asylum physicians are best acquainted. But I beg of you not to consider this as a pathognomonic symptom, as some writers would have you believe. Many cases of dementia-paralytica never get beyond "feeling very well," some others are neither exalted nor depressed, and a small number have depressing hypochondriacal delusions. In pleading for the early diagnosis of this disease I refer to cases in which exaltation and maniacal excitement, as well as epileptiform and apoplectiform attacks have not yet appeared.

(7) The reflexes are as a rule greatly exaggerated. Extremely strong knee-jerk, sometimes ankle-clonus, and nearly always wrist-jerk can be demonstrated. In cerebral syphilis and some cases of cerebral neurasthenia we meet with equally high reflexes. The explanation is to my mind simple. I still believe that knee-jerks, etc., are reflex spinal acts (though by far the most rapid of all reflex actions). The healthy cerebral cortex constantly exerts a restraining or inhibitory effect or influence upon the spinal centres. If the cerebral cortex be diseased, by internal inflammatory changes as in paresis, by wide-spread arteritis as in syphilis, or by simple (?) functional exhaustion, this inhibitory influence is reduced or almost lost; hence the increased reflexes,<sup>11</sup> and the unrestrained emotional manifestations. These are the symptoms from which a early diagnosis of dementia-paralytica can be made by the practitioner; nay, should be made by him.

(1) A positive diagnosis can be made, I believe, from the speech alone,<sup>12</sup> but perhaps it is too much to ask the general practitioner to risk so much on one symptom. Impaired speech with unequal motionless pupils, high reflexes, and slight mental symptoms should, however, oblige the physician to make a diagnosis, and remove the patient from business.

(2) Fixed, small or unequal pupils with changes in character, increased reflexes, and confusion in manner, should lead to a suspicion of dementia-paralytica. Even the small fixed pupils alone should, I think, excite suspicion, and lead to careful observation of the patient.

(3) Mental slowness and inaccuracy, with any one of the symptoms referred to should cause a strong suspicion of incipient "paresis." The same is true of inexplicable changes in the moral character of a subject above twenty years of age.

<sup>11</sup> Two years ago I saw a perfectly healthy patient presenting tremor, imperfect speech, unequal pupils, conscious failure of memory, etc., on taking leave of him, he put the few, which his wife had handed him, into his over pocket, and at the door shook hands with her. The poor lady, who has since died, was instantly aware of these errors and laughed heartily at them.

<sup>12</sup> In a small minority of cases the knee jerk is absent or much reduced and the patient describes sharp pains in various parts of the body. These are cases in which the posterior columns and roots of the cord are affected by sclerosis; it is yet a question whether this is a coincidence or whether it is an extension downward of the cerebral changes.

<sup>13</sup> The foot note on this page refers to such a case, brought to me by Dr. Conrad of New York.

(4) Dementia-paralytica is, I might add, much more frequent among women than is generally held by authorities. They can more easily cover up signs of mental failure, and they seldom exhibit exaltation. Guided by the points I have given as of great diagnostic value, you will be able to recognize a good many female cases.

(5) A general character of great value is the gradual slow onset of symptoms. When an adult rapidly becomes demented (foolish in manner, inattentive to his person, even to the point of not controlling his evacuations), has unequal pupils, and large quasi-choreic ataxic tremors with early convulsive seizures, it is possible that the case is one of cerebral syphilis, which may be cured by heroic treatment.

(6) You should not be discouraged in your diagnosis by an apparent return to health after a few months, because extraordinary remissions, lasting several months, occur in the course of dementia-paralytica.

### III. CEREBRAL TUMOR.

I had intended saying a good deal about the early diagnosis of cerebral tumor, but the subject is so large that there would not be time for its careful consideration this evening. Let me just enumerate the following principal symptoms of encephalic tumor, namely:

*Headache*, local or diffused.

*Paralysis* of various distribution, and almost invariably progressive in development.

*Convulsions*, usually having the same distribution as the paralysis; occasionally general spasm. Either of these symptoms may precede the other, and no special value attaches to the order of precedence.

*Opisthotonus*.

*Vomiting*, usually without nausea.

*Anæsthesia*, very rarely; usually of same distribution as the motor symptoms.

*Mental dulness*, stupor, and even transitory coma.

*Aphasia*, amnesia, sensory or motor.

*Hemianopsia*, dark half-fields on side opposite the tumor, and on same side as the motor and sensory symptoms. If the optic nerves are normal, the papillary reaction is completely preserved.

*Choked disk or neuro-retinitis*, with hæmorrhages in the retina; succeeded by

*Atrophy of the optic nerves*, but this symptom may appear primarily.

*Paralysis* of one or more cranial nerves independently of body-paralysis.

*Increased temperature* of scalp over supposed site of tumor.

*Localized tenderness* to percussion over supposed site of tumor. Both these symptoms are unusual and of uncertain value.

*Slow pulse* occurs when the intra-cranial pressure is much increased, and often is co-occurent with deep stupor lasting hours or days. Repeated attacks of stupor with slow pulse during the course of a case of encephalic tumor, are very strongly indicative of distension of the ventricles by fluid.

Unfortunately none of these symptoms is pathognomic; not one has nearly the value that fulgurating pains have in tabes, or defective speech in dementia-paralytica.

At one time it was hoped that choked disk would prove of greater value than any other single symptom, but we have known for ten years that many cases even

of enormous tumors do not present choked disk, and that, on the other hand, this ocular lesion occurs in persons who have no intra-cranial disease. Indeed, in my experience as regards tumors of the hemispheres the rule is, that the optic nerves are normal. When the tumor is situated in any other part of the encephalon, choked disk seldom fails to appear; often very early.

A diagnosis must consequently be made by studying the grouping and the mode of progress of the symptoms. The latter I believe to be most important. For instance, the co-existence of recurring localized spasm (Jacksonian spasm) with a progressively increasing paralysis of the same part as that which is convulsed (let us say one arm or one leg for example), may sometimes justify the diagnosis of cerebral tumor, even if all the other symptoms are absent.

Local or Jacksonian spasms, occurring in a previously healthy adult patient, should always excite suspicion of brain tumor. The same is true of choked disk alone, (when Bright's disease can be excluded).

With reference to the value of localized spasm it should be added that there are a few cases on record which would seem to indicate that they may occur in hysteria—very rarely of course. Besides, if the paralysis following the spasm (of one forearm let us say) is only slight or transient, we must remember that a superficial or cortical lesion, not a tumor, may cause the symptoms. I have reported such a case in which a patch of localized meningitis over the facial centre was diagnosed during life and verified post mortem.<sup>13</sup> I should add that the diagnosis of cerebral tumor may now be made so early (that is, when the tumor is very small) that immediate surgical interference may be of no service. In a case of mine operated by Dr. R. F. Weir, the tumor was deeply seated in the white substance, and was not larger than a small almond. It seems a miracle that we detected (by palpation) this small sub-cortical sarcomatous mass.<sup>14</sup> Recently Dr. Joseph D. Bryant operated on a case in which I had (in conjunction with Drs. Fuller and Wolff, of Hartford) diagnosed a tumor under the motor centre for the left leg. The operation failed to reveal the tumor, though most careful palpation was practised and incision made through the cortex. A careful autopsy made on the partly hardened hemisphere revealed a gliomatous mass about half an inch in diameter, just about in the anticipated location. The tumor being of about the same consistency as the surrounding white substance, could not be detected by palpation. Again, about a year ago, Dr. Weir operated in a case in which I felt quite sure that there was a tumor. None was found at the operation, and we were naturally much disappointed. A regular autopsy was not allowed, but Dr. Weir removed the whole of the right hemisphere with his fingers, through the large trephine aperture, without finding a tumor. However, judging by my last case, the one operated in Hartford, I feel quite certain that a small sub-cortical glioma or sarcoma did exist in this case, and the coarse post-mortem examination could not have revealed so small a mass. It is highly desirable that in all such cases the brain should not be cut in pieces at the time of the autopsy, but placed in hardening fluid for more careful study later.

<sup>13</sup> Journal of Nervous and Mental Diseases, vol. xiv, June, 1887. (Case 1.)

<sup>14</sup> American Journal of the Medical Sciences, July, August and September, 1888.

The practical conclusion to be drawn from these three cases is, that surgical interference may be attempted too early, that is, when the tumor is too small to be recognized, especially if it be sub-cortical.

(To be continued.)

### SUPRA-PUBLIC CYSTOTOMY FOR THE REMOVAL OF FOREIGN BODIES WITH REPORT OF A SUCCESSFUL CASE.<sup>1</sup>

BY HOMER GAGE, A.M., M.D.,  
Surgeon to Worcester City Hospital and to Memorial Hospital.

INCREASED familiarity with the use of the lithotrite has made cystotomy for the removal of foreign bodies from the bladder as much the exception now, as it formerly was the rule. Of the 240 cases collected by Denucé there were, prior to 1830, 27 extractions and 109 cystotomies; between 1830 and 1856, 22 cystotomies and 101 cases of extraction. Poulet's figures, brought up to 1879, show substantially the same proportion; and there can be no doubt but that these later results represent a genuine and permanent advance in the management of these very annoying cases. Whenever the foreign body is small and can be easily crushed like a stone, or whenever there is reason to believe that it is so small and flexible that it can be easily withdrawn from the urethra, the case admits of no argument. Extraction by means of the lithotrite is then the safest and quickest as it is always the most brilliant procedure. But there are many cases in which the nature and shape of the foreign body, or the existence of urethral or prostatic obstruction makes extraction the more dangerous and cystotomy the more conservative method.

The problem of choosing between these operations lately presented itself to me in the case of a young man in whose bladder a piece of soft rubber catheter had been broken off six weeks previously, and it is to a brief consideration of those cases in which the whole or a piece of a catheter or bougie constitutes the foreign body to be removed that I wish particularly to call your attention. Such cases generally result from the use of defective or worn out instruments, although the large proportion which follows their use in the hands of patients themselves would indicate that unskillful or careless manipulation add much to the probability of their occurrence. The jointed silver catheter becomes unlocked at the joint, a silver catheter which has been once broken and soldered is very liable to refracture at the old place, and in one of the cases which will be found in the accompanying table (Mr. Heath's) an old man succeeded in leaving two fragments of a metallic instrument in his bladder. Such accidents are, however, far more common from the use of silk gutta-percha and soft rubber instruments. They crack easily, especially when old and dry, and when once cracked are easily broken.

From the records at my disposal I have collected the following cases in which a piece or the whole of a catheter or bougie has been removed from the bladder. They go back only to 1879:

#### EXTRACTIONS.

(1) A small piece of a silver catheter removed from a patient seventy-one years old, after being retained twenty-four hours,

<sup>1</sup> Read before the Worcester District Medical Society, November 15, 1890.

by means of lithotrite. A second piece, one and three-eighths inches long, after failure with lithotrite, was removed by perineal cystotomy. Heath: *Lancet*, 1879, i, 478.

(2) A No. 10 gum-elastic catheter which had been retained in the bladder of a man seventy years old for seven months. Abbe: *New York Medical Record*, xx, 705.

(3) The whole of a soft rubber catheter which had been retained twenty days. Cheine: *Edinburgh Medical Journal*, xvii, 741.

(4) A No. 4 pilot bougie, twelve inches long, which had been retained two days in case of stricture. Edwards: *British Medical Journal*, 1882, i, 816.

(5) A No. 3 pilot bougie passed for relief of stricture. Harrison: *British Medical Journal*, 1882, i, 816.

(6) A gutta-percha catheter extracted after incision of urethra. Lediard: *British Medical Journal*, 1882, ii, 889.

(7) Five inches of a soft rubber catheter retained sixteen hours, extracted after incision of urethra. Porter: *Boston Medical and Surgical Journal*, cxv, 399.

(8) Whole of a soft rubber catheter retained twenty-four hours. Extracted by means of a wire bent over a steel sound. Osborn: *Journal American Medical Association*, 1883, i, 717.

#### PERINEAL CYSTOTOMIES.

(1) One-half of a fine bougie which was being used as a guide. Teevan: *Lancet*, 1879, i, 478.

(2) A gutta-percha catheter. Bryant: *Lancet*, 1879, i, 478.

(3) Three and three-quarter inches of a No. 13 English silver catheter retained three weeks in a patient who had retention complicating cancer of sigmoid flexure. Lediard: *British Medical Journal*, 1882, ii, 889.

(4) One inch of a gum-elastic catheter. Lediard: *British Medical Journal*, 1882, ii, 889.

(5) One-half of a gum-elastic catheter after being retained one year. Fayer: *Lancet*, 1883, i, 545.

(6) Four and one-half inches of a No. 22 Nelaton catheter retained four days. Evacuator failed to remove it. Keen: *Philadelphia Medical Times*, March, 1888.

(7) Two or three inches of a soft rubber catheter retained six or eight months. Three calculi removed, each containing bit of catheter. Halsted: *New York Medical Journal*, xxxix, 227.

#### SUPRA-PUBLIC CYSTOTOMIES.

(1) Piece of a jointed silver catheter, the bladder was not sutured. Hyatt: *North Carolina Medical Journal*, December, 1883.

(2) Whole of a No. 14 elastic bougie. Bladder was sutured but leaked for one week. Orłowski: *Deutsch. Zeitsch. f. Chir.*, December, 1885.

Among these 17 cases there are eight extractions—seven by means of the lithotrite and one by means of a wire bent over a steel sound, seven perineal cystotomies, and two supra-public cystotomies. For this particular class of foreign bodies the cutting operation seems to have been resorted to relatively more often than one would have expected from the earlier and more comprehensive tables of Denucé and Poulet. The introduction of antiseptics and the safer technique secured thereby have undoubtedly done much to contribute to this result. Of the 17, all recovered but one—a man seventy years old with cancer of the sigmoid flexure, who succumbed seven weeks after a median perineal operation to pyæmia. Of the eight extractions three were attended with great difficulty, and in one of them the procedure failed. Mr. Heath (Case 1) succeeded in withdrawing a small bit of the end of a silver catheter through the urethra, but his lithotrite failed to remove or crush a second piece which perineal cystotomy proved to be only one and three-eighths inches long.

In Mr. Lediard's and Dr. Porter's cases pieces of a gum-elastic and of a soft rubber catheter respectively, were extracted only after incising the anterior urethra. In Mr. Keen's case (No. 17) extraction by means of an evacuator had to be abandoned in favor of cystotomy. These cases recovered promptly, but they suggest certain dangers and difficulties attendant upon extraction. Laceration of bladder or urethra must be avoided if possible—if unavoidable it is better that it should be by incision from without so that the extent of the damage may be under the direct

control of the surgeon. Whenever the foreign body is a fragment of a metallic instrument, the lithotrite is at a great disadvantage. It can only extract it when the direction of the long axis of the fragment corresponds to the long axis of the instrument. Such a correspondence can be secured only by repeated trials. With each trial there is beside the risk of catching the bladder-wall, the resistance of which it is difficult to distinguish from that of the foreign body, the additional risk of injuring the bladder with the fragment, one end of which is usually ragged and sharp. In all such cases, therefore, the cutting operation is to be preferred. With gutta-percha, gum-elastic, or other flexible instruments, it is somewhat different. Experience has proved and our table illustrates that even a whole catheter or bougie may be withdrawn with but little difficulty even when doubled on itself. The same uncertainty about catching the bladder-wall must, however, be taken into account with the added risk of lacerating the urethra. If the instrument has not remained long enough to have rendered the urine ammoniacal, or to have become encrusted with a calculous deposit, so that it presents a comparatively smooth surface, and if the urethra is of normal calibre, extraction by means of the lithotrite is certainly the simpler and safer operation. A foreign body, however, which has been in the bladder so long that cystitis with ammoniacal urine has resulted, and has become covered with a rough and sharp crystalline deposit can hardly be withdrawn from the urethra without considerable risk. Dr. Abbe (Case 4) has successfully removed a No. 10 gum-elastic catheter which had been retained seven months and was everywhere encrusted. It can probably be done again. But surely any one would hesitate to introduce a catheter from without which presented a rough, ragged surface, and was covered with foul decomposing urine lest it should cause urethral laceration and septic infection. The same reasoning applies with greater force when a stricture makes urethral laceration by division or internal urethrotomy a necessary preliminary to the introduction of the lithotrite. Upon these grounds, in my own case, I rejected extraction and preferred cystotomy.

Then came the necessity of choosing between the perineal and supra-pubic operations. The revival of an operation which has once been condemned after fair trial, can be justified only by the disappearance of the causes which led to its abandonment. In the case of supra-pubic cystotomy these were chiefly two. First, the danger of wounding the peritoneum and opening the peritoneal cavity, and second, the increased danger of urinary infiltration and septic infection. The former has been happily removed by the experiments of Garson, Peterson, Strong and others, which have been confirmed by a large and increasing experience with a technique founded upon their observations. Distension of the bladder with or without simultaneous distension of the rectum lifts the anterior reflexion of the peritoneum far enough above the pubes so that it can be easily avoided and need not be seen during the operation. The dangers of urinary infiltration and septic infection have been diminished by the use of antiseptic irrigation and the open treatment of the external wound, so that the probability of their occurrence is no greater than after the perineal incision. Its immediate dangers are then no greater, and it has the advantage of avoiding entirely what is a rare

but sometimes very troublesome complication of the perineal operation, namely, hemorrhage. The plexus of veins in the prevesical fat can often be dragged one side with the finger, or if not, is perfectly accessible, and can be easily secured. The supra-pubic incision possesses the further advantage of making the bladder much more accessible, and of enabling the operator when necessary to see as well as feel. A foreign body which has been partially encysted or whose sharp ends have caused ulceration or thinning of the bladder-walls can in this way be removed with very much less danger of rupture — moreover it can always be removed even when from the perineal wound it may be inaccessible. The low operation has besides, certain rare, but possible sequences which cannot be wholly disregarded. Greig Smith says: "In this Bristol district, where stone is rare, I have seen in the last nine years five operations for perineal fistula following perineal lithotomy, and I have been concerned in the treatment of one case of stricture and one of fistula from the same cause. . . . Stricture, fistula, sexual incompetence — separately or combined must be admitted to be rare sequences of perineal lithotomy." Such accidents are as likely to follow the removal of a piece of catheter as the removal of a stone and the supra-pubic operation appears to be free not only from these but from any other complications. I, therefore, selected it in the following case.

R. D., a French-Canadian, twenty-three years old, had gonorrhoea two years ago, and has had a slight gleet discharge ever since; has never had retention, but has observed that the size of the stream was slowly diminishing. In August last, while in Canada, he was induced to go to a hospital for the relief of stricture. On his return toward the end of the month, he had a well-marked purulent urethritis. There was pain at the end of micturition, and the last drops of urine were decidedly bloody. He was obliged to get up two or three times to pass water at night, but there was no increased frequency by day. Such was his condition when I saw him about September 1st. He said that while at the hospital a bougie had broken off in his bladder, and that he thought his trouble resulted from the retention of a fragment. I thought his story highly improbable, and gave it little attention. The gonorrhoea soon stopped, but the pain and blood continued, and he began to complain of pain and distress in the perineum. Accordingly he entered my service at the City Hospital, October 2d, at which time I searched the bladder under ether but found nothing. His urine at this time had a specific gravity of 1,016, was cloudy, alkaline, and contained a trace of albumen with a sediment of pus, blood and considerable mucus. Blistering the perineum and irrigation of the bladder were alike of no effect. Finally, in answer to my inquiry I heard from the Canadian hospital that a piece of a No. 11 soft rubber catheter was probably responsible for his trouble. It had been in the bladder now about seven weeks, and on October 21st after distending the bladder with about eight ounces of boroglyceride solution, I made an incision in the median line two and a half inches long extending from the top of the symphysis pubes upwards. The recti were held apart, their attachments to the symphysis partially divided, and the bladder-wall incised for about one inch. The piece of catheter was then withdrawn with the fingers, and the opening closed with an interrupted silk suture. A drainage-tube was

placed in the external wound and a catheter tied in the urethra and connected by a rubber-tube with a bottle hanging by the bed. The wound was dressed with a dry antiseptic dressing. There was no leaking from the bladder wound until the sixth day, when the catheter was left out. On the next day it was replaced, and except some suppurative about the sutures of the external wound no further trouble occurred. The catheter was permanently removed November 4th, and on the 6th, sixteen days after the operation, he was discharged well.

The fragment removed was doubled on itself at the upper end of the eye, and was covered with a crystalline phosphatic deposit. It was two and a half inches long and weighed thirty-one grains.

There are two points in connection with the operations which demand at least a moment's consideration, namely, the value of rectal distension and the advisability of suturing the bladder. I followed Greig Smith in not using the rectal bag. Its advantages are of course, that it lifts the peritoneum further out of the way, and that it raises the floor of the bladder into a more accessible position. The latter is a great advantage when operating upon tumors of the bladder or prostate; for the removal of foreign bodies that lie within the cavity, it is unnecessary. The experiments of Strong show that the peritoneal reflexion is a little higher when both bladder and rectum are distended, than when the bladder alone is filled. The difference, however, is slight and unless it can be shown to possess some very positive advantage, it seems to me that the chance of injuring the rectum makes the use of the rectal bag quite inadvisable.

The propriety of suturing the bladder is still *sub judice*. König in his report before the International Medical Congress of 1886, absolutely condemned it. Eigenbrodt, from an experience of thirty-eight cases in Trendelenberg's clinic, regarded complete closure by suture as not yet justifiable. Sir Henry Thompson rejects it, and Jacobson thinks "the risk run is greater than any advantage gained." The record of eight deaths and seventeen failures out of forty cases collected by Meyer in 1884, was not encouraging. On the other hand it cannot be denied that when primary union of the bladder wound can be secured, it not only prevents septic infiltration, but adds very greatly to the comfort of the patient, as well as to the rapidity of his convalescence. Even if not uniformly successful, still if it can be done without increasing the danger, suture is surely worthy of trial. Of 100 cases collected by Watson in 1889, suture was successful in thirty-five, certainly an encouraging showing. Moreover, he found that whenever serious results had followed suture it was because the outer wound had been closed. Accordingly, he follows Kraske, Eltzmann and Meckel in recommending that the outer wound be left open. It may be packed with iodoform gauze or partially closed around a drainage-tube. Managed in this way it is difficult to see what harm can be done by attempting the closure of the bladder wound except where it is desired to leave it open for purposes of irrigation or drainage. In applying the suture the edges of the wound must be turned in, and the outer surface of the bladder on either side of the incision brought into close and accurate apposition. Very little of the edge is to be turned in, not more than one-sixteenth of an inch if possible, but the careful turning in of that little and the accurate adjustment

of the sutures, will be found to be two of the chief elements of success. A third will be found in taking advantage of the submucosa in placing the sutures. Each stitch must include something stronger than the muscular walls else it would not hold. It must not penetrate the mucous membrane or it would become encrusted with salts or form a channel for urinary infiltration. As was pointed out by Halsted and Mall in intestinal suture one can readily familiarize one's self with the sense of resistance which the submucosa makes to the passage of the needle, and so strong is this tissue that if only a few fibres are caught sufficient strength is given to the suture to allow of its being firmly tied. In sewing up the bladder in my own case precisely the same sense of resistance was encountered in the submucosa that I have felt in experiments on intestinal suture, and precisely the same advantages are, I think, to be derived from making use of it. The uninterrupted square suture of Cushing or any of the various forms of intestinal suture may be adopted. If the interrupted form is used, the stitches must be applied as closely as possible, for accuracy and closeness of adjustment are of much more importance than the kind of suture. Either catgut or silk may be used. I prefer silk because it admits of a finer needle. I had a No. 8 straight milliner's needle such as I have used in intestinal suture, but found it so long that I had great difficulty in applying my sutures. The wound in the bladder lies below the surface of the abdomen, and a needle more than one inch long can only be used at a disadvantage. On this account I failed to secure an absolutely accurate adjustment of the edges of my wound, and to this I attributed the slight leakage which subsequently occurred. I am, however, satisfied that my suturing, imperfect as it proved to be, made the period of convalescence very much shorter than it would have been had it been left undone.

#### THE NECESSITY OF AN EMERGENCY HOSPITAL IN THE BUSINESS DISTRICT OF BOSTON.<sup>1</sup>

BY GEORGE W. GALVIN, M.D., BOSTON,  
Surgeon for Old Colony and New York & New England Railroads.

THE subject for discussion this evening is one which I have had under consideration for the past eight years. Believing, as many medical men do, that in order to become a successful general practitioner, it is necessary to locate yourself in a thickly populated place, I selected the South Cove district. In all large cities the cream of the practice goes to the physicians and surgeons who have established themselves in the confidence of the public by their excellent work, and their connection with the various hospitals and medical schools, while the younger men content themselves with the overflow from their seniors in the profession and an occasional emergency case which may bring them into more or less prominence.

It has been my good fortune to receive a large share of the patronage of the latter class. The past five years have demonstrated to me, and a few colleagues who have been associated with me, that the time has arrived when something should be done for the great number of casualties occurring in the business district, requiring immediate surgical or medical aid.

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, November 19, 1890.

The following are the different classes of cases which come under observation:

(1) Railroad injuries to employees of the three southern railroads.

(2) Casualties from machinery, elevators, chemicals, etc.

(3) Immediate medical assistance to the employees and people taken suddenly ill in the large stores, warehouses, depots and in the streets.

(4) The fourth class is one whose number is yearly increasing in every district of the city, namely, those unfortunate beings who become suddenly insane and require immediate restraint.

Before considering the different classes mentioned, I wish to say that I have no criticism to make of any hospital in this city. The two general hospitals are famous, both in this country and abroad. The demands made upon the different staffs during their time of service is enormous. The best part of their lives and their most valuable time is given to the institutions with which they are connected. Many of the surgeons and physicians of this city are famous from one end of the continent to the other, in consequence of the brilliant work performed in and out of the hospitals. We will take of the first class mentioned, namely, Injured Railroad Employees of the New York and New England Railroad, Old Colony, and Boston and Albany Roads. The great distance that the three railroad stations mentioned are from the Massachusetts General and Boston City Hospitals, show to a medical man how much valuable time must be lost in transporting the injured across the city. The shortest possible time in which the police ambulance can be obtained is twenty minutes. The trip to the hospital, if the going is to be made with ease, will occupy from twenty to thirty minutes more. The wait in the accident-room, (for the arrival of the surgeon) if the patient arrives in the afternoon or evening may be nearly an hour, rarely less than half that time. You can readily see that the time occupied in waiting for the ambulance, conveyance to the hospital and the wait for the arrival of the attending surgeon, consumes from one hour and a half to two hours of most valuable time to the patient. The long ride over rough and uneven pavements, I have frequently observed, to be more trying and exhausting to the injured one, than a journey by rail from a distant town to this city. With prompt and efficient surgical service stationed at a small hospital in the South Cove district, much of the suffering of injured railroad men could be quickly relieved, hæmorrhage effectually controlled, shock combated, broken bones properly adjusted, and after the patient had sufficiently rallied to be removed to the Massachusetts or City Hospital, the journey could be made both with ease and safety. So much for the railroad man who has received a grave injury.

By far the larger number requiring the services of a surgeon are those suffering from mangled fingers and toes, fractures and dislocations of the shoulder, fore-arm and ankle, scalp wounds and moderate concussion of the brain.

When this class goes to the hospital, they are treated in the out-patient department. Oftentimes the injury is received early in the morning. He goes to the hospital, awaits his time to be treated, which is much longer than if his injury is a severe one. It may not be known to the profession that all railroad superintendents make it a point to give light work to those who have been hurt, but are able to go about, without

a loss of pay; but again the time consumed in going to the hospital, waiting for treatment and return home, occupies most of the forenoon for a man working, or residing in this district. Consequently he is laid off, very frequently without pay until his wounds are healed and he is able to return to duty. Four or five years ago I interviewed the general managers of the Old Colony, New York and New England Railroad and Boston and Albany Railroad, as to the feasibility of establishing an accident-room in the United States Hotel. My idea was to have two surgeons and an assistant, so that aid could be obtained at any time of the day or night. Cases requiring immediate entrance to the hospital would be taken there on the ambulance by the surgeon. Should an accident occur on the road, he was to be telegraphed to hasten to the scene of the accident with authority from the road to call upon men who were competent to assist him. All the minor injuries were to be attended to at the accident-room.

Thanks to Mr. J. R. Kendrick, of the Old Colony Road, through whose influence with the managers of the other corporations, my idea was adopted. A course of emergency lectures was given by me to the employees of the different roads; and, for a time, nearly all of the cases came under my observation, or for treatment. In a measure, the New York and New England Road send employees to me. The Old Colony referred all cases to the accident-room at the time of the late Quincy accident. My office was made the headquarters for all necessary surgical supplies, and for the disposition of many of the cases. Of the three large railroad corporations in this district, the Old Colony is the only one which makes proper provisions for its employees and the travelling public.

The second class of cases I mentioned, are those injured by machinery, elevators, chemicals, etc. Very few would believe that they form the largest number mentioned, but when we consider the thousands employed in this district, it is not surprising that the number yearly reaches into the hundreds. My experience has taught me that this class, as a rule, do not care to enter the hospital as indoor patients, much preferring to receive temporary treatment, and later consulting their own physician. They are liable to demand surgical or medical assistance on the spot. The time lost in waiting for a doctor to respond from Park Square or Boylston Street is invaluable. As proof of this, I can recall several cases where I have been obliged to amputate limbs in order to remove them from an elevator or machinery.

The calls for a doctor from the large stores, warehouses, depots, and people taken suddenly ill in the street, form a large class. The only way for them to obtain quick relief, is to have a place in that neighborhood, where the public can obtain a rapid response to their call.

The last class, of which I will speak, are those of acute mania.

What Boston needs more than an emergency hospital, is a place of detention for those unfortunates who, without a moment's warning, become violently insane, and call for immediate restraint, for safety to themselves and the public at large. At any time of the day or night, a physician may be summoned. If the services of an emergency expert in mental disease, or the judge, cannot be found to sign committal papers, the person is taken to the tombs and detained until the mental condition is looked into by two phy-

sicians, the judge passes upon their decision, and the institution designated to which the patient is to be transferred.

It is hardly necessary to state that this is a deplorable condition of affairs, when you consider that any resident of this city, a stranger from a distant State, no matter what his social standing may be, is obliged to be associated with criminals of every class.

## Clinical Department.

### A CASE OF ANEURISM OF EACH CAROTID, ONE INVOLVING THE INNOMINATE.<sup>1</sup>

BY W. F. TEMPLE, M.D.

ELLEN O'D., age sixty, came to America, thirty-seven years ago. Her family history is good; so far as known there has been no case of heart disease or any constitutional taint. She is the mother of several children, all of whom are well and strong. Mrs. O'D. herself is a very well-preserved and intelligent woman. Her life has been remarkably free from sickness, for with the exception of subacute rheumatism, from which she suffered some twenty years ago, she has never been ill.

She was questioned and the history of this attack of rheumatism carefully sifted; it seems that when about forty years of age this sickness occurred; there was pain and swelling of both feet and ankles, no other joints affected, continuing for ten weeks; she was not confined to the bed, and never suffered in any other part of body. Since then she has never had a recurrence or suffered from rheumatic pains, even in damp weather.

The present state of health is good; she does the ordinary work about the house with exception of washing and ironing. Appetite good, and all the functions of the body regular.

Ten years ago noticed a slight beating in left side of neck, which became apparent to others only about two years ago. For this palpitation consulted a physician. Came to the Clinic at the Boston Dispensary some three weeks ago, complaining only of nervousness and the palpitation which is now quite marked, and, has also when excited, a motion or agitation of the head which is only observed after one has conversed with her for some time.

She has never been affected with dyspnoea or dizziness, has never fainted in her life, has noticed a sudden slight blur before the eyes for a few seconds at times during the past year and a half.

Physical examination: Pulse 100, strong, wiry hammer-like (so-called Corrigan's pulse). About the middle of the left side of neck, corresponding to position of the middle third of the left carotid artery, a pulsating tumor was noted about the size of a pigeon's egg, globular in form; on manipulation, lateral expansion and a distinct thrill to the touch were recorded; on auscultation, heart sounds very loud, a peculiar bruit, low in pitch and musical in character. The agitation of the head was very noticeable during the examination, occurring with every heart beat.

On examining the right side of the neck pulsating tumor was visible, commencing at the interclavicular notch, extending upward and outward about the size of a hen's egg, ovoid in form, the upper portion somewhat fusiform, as in the other tumor expansion, and there was noted also on auscultation the bruit which was also heard over the subclavian artery.

The heart was enlarged. Over second interspace to right of sternum, a double murmur was detected also heard over the axillary and brachial arteries on the right side over a circumscribed area. At the apex the murmur was also detected, and was traceable directly back to the second interspace, where it was much more distinct than at any point of examination. There was no atheromatous condition of arteries. There is then an aneurism of the middle third of left carotid; an aneurism of lower third of right carotid involving the innominate and possibly a portion of the subclavian.

The consideration of treatment was not called for in the case.

It has seemed to me worthy to be put on record for the following reasons:

(1) Multiple aneurisms are rare. In the History (Medical & Surgical) of the War, I was unable to find an account of any such.

(2) The extensive pathological changes which existed and had existed for seven years without causing any more serious trouble.

(3) To note the freedom from anxiety which the patient displayed and to emphasize the fact that very grave lesions may not be fatal for years, or eventually the person die from some other cause, and that one cannot be too cautious in giving a prognosis in chronic though serious cases; so that the patient may be as free from unnecessary suffering as possible. Hence we can all bear in mind that we are not executioners.

The crumpled and crushed form of the human ear is accounted for by Professor Garrison as a result of the habit of lying on the side of the head, which habit has been induced by the increasing weight of the brain.

<sup>1</sup> Read before the Massachusetts Medical Society, Suffolk Division, at a meeting for Clinical Medicine, Pathology and Hygiene, November 19, 1890.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOL- OGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

REGULAR meeting, Wednesday, November 19,  
1890, DR. E. G. CUTLER in the chair.

#### PATHOLOGICAL SPECIMENS.

DR. E. W. CUSHING showed

AN EXTRA-UTERINE FETUS AND PLACENTA, REMOVED AT THE NINTH MONTH BY ABDOMINAL SECTION.<sup>1</sup>

He also showed a uterus containing a polyp and other myomata, removed by supravaginal hysterectomy, and made the following statement in reference to the case:

This case I wish to show because it is rare to have such a concatenation of symptoms or conditions as there was here. The woman was sent from Maine to the Charity Club Hospital with the history that she had been bleeding for about a year, and had been bed-ridden about two years, and more or less of an invalid for many years. She was forty-one years old. In the vagina a large mass presented and filled the whole passage. Above, there was an indistinct mass in the abdomen. It seemed pretty plain that the mass in the vagina was not cancerous, but myomatous; it felt hard and smooth, and going far up behind it the cervix could be felt constricting it.

She was a chronic invalid, much more so than this mass in the vagina would account for. I opened the abdomen, and the first thought was that the thing was malignant. It was adherent, but I made out some of these knobs, showing clearly that it was a fibroid. The right ovary and tube were adherent, and the latter was dilated and full of pus; these were enucleated with a good deal of difficulty. The left tube was a pus-sac, and so degenerated that when it was torn off it was difficult to stop the hemorrhage, which was accomplished by passing a needle and silk ligature under the insertion of the tube.

The myomatous mass in the vagina was removed by traction and torsion; it was necessary to incise the perineum in order to deliver it. The uterus, meanwhile, was steadied by the hand on the inside of the abdomen.

On the whole it seemed safest to remove the uterus by supravaginal hysterectomy, although the patient was very fat, and this was done in the usual manner, with a rubber constrictor and crossed pins, a glass drainage-tube being used.

She is now doing well three days after the operation, but it is impossible to say whether she will recover or not. It is quite rare to have a myomatous polyp and also other myomata in the walls of the uterus as is the case here which makes this specimen worthy of consideration. Mr. Tait says: "The cases in which we can diagnose and remove a uterine [myomatous] polypus, where there are at the same time other intramural myomatous growths, are so rare that I have never met with one; whilst, on the other hand,

I have removed a very large number of myomatous polypi, in which there were no other growths."<sup>2</sup>

DR. JOHN HOMANS, 2ND: I think it is to be regretted that there are not more members of the Section here to see the first specimen, that of extra-uterine pregnancy. Any one, I think, at all interested in abdominal or general surgery must congratulate Dr. Cushing on the success, on the skill in operating and the result of treatment. A case of that sort marks a distinct step in advance; and it is also interesting as bearing on the point now under discussion whether cases of that sort should be treated by electricity, or surgically. In New York and Chicago there are quite a number of gentlemen who are strongly in favor of using electricity, and who say that the knife should never be used, or at least very rarely. This case goes to show that used properly and with skill, the knife is in many cases, and, I believe, is in almost all cases preferable to electricity; electricity not affording by any means as great a chance of recovery for the patient, and sometimes even if it does result in recovery, this is achieved only after months of suffering with more or less fever and general disturbance.

DR. A. N. BLODGETT: What course would Dr. Cushing pursue or recommend in a case of this kind provided the woman showed no alarming symptoms at the normal termination of pregnancy, and experienced no trouble afterwards, supposing, of course, that the diagnosis of extra-uterine foetation had been or might be established; what course would be pursued in such a case provided no indications of labor were present and that no symptoms of septicaemia or any other trouble occurred?

DR. CUSHING: There are two factors in such a case: Whether the child, at what ought to be the termination of pregnancy, is dead or living. If the child is living, it has certain rights which might impel one to perform an operation immediately, with the hope of saving the child. If that is done there will be much greater danger in attempting to deal with the placenta. It is a very serious matter to remove the placenta while the circulation is still active. If the child is dead, or if the community and the family do not admit the imperative need of interfering to save the child, I think there is very little doubt that the mother's chances are better after the child has been dead a while, in order that the placenta may be diminished as to its circulation, as in this case. Given the fact of an extra-uterine foetation, and everything going on comfortably a month or more after the child is dead, the question is, whether then it ought to be removed or left alone. I should say by all means an operation was indicated for this reason: a great many women die with cases of this kind by sloughing, by slow supuration, or by decomposition of the contents of the sac, and the cases on record where such a child has been carried for years or for life, are very few, perhaps twenty in all. There have been a number of operations of necessity, when an abscess had already formed, so that the question is, whether it is better to perform the operation comfortably and before an abscess has formed, or to take the chances, at a later period. When we can only say that some twenty women in the civilized world, during the last two hundred years, are known to have lived through this, and carried their children a long period; and can easily count up twenty times that number, who have died of this affection, that is, of the

<sup>1</sup> See page 39 of the Journal.

<sup>2</sup> Diseases of Women and Abdominal Surgery, Am. Ed., p. 176.

presence of a dead extra-uterine foetus; it seems to me that the removal of the sac is clearly indicated, as you would remove any other tumor; and it is not so particularly difficult either, I fancy, at least, it was not in this case.

There was a case under the care of the same physician, Dr. Frost of Peabody, some years ago, which went through the same course, was apparently doing well, but finally counsel was urged and he was advised to dilate the uterus, and did so. Septic infection occurred, and she died within ten days, whether or not owing to the treatment, has remained a mystery. It was the result of that case of *expectant* treatment that led the physician and family to make up their minds to operation in this case.

DR. W. F. TEMPLE reported

A CASE OF ANEURISM OF EACH CAROTID, ONE INVOLVING THE INNOMINATE.<sup>3</sup>

DR. JACKSON: I have nothing to add to the history of the case which Dr. Temple has given. I first saw the woman in July, and she made several visits at the Dispensary during my service. She came complaining of headache, and made no mention of any dyspnoea, and did not speak of the swellings in her neck, though she knew of their existence, and apparently considered them of no great importance. The chief symptom as I said, was headache. She was able to get about perfectly well. She came from Chelsea, I think, to the Dispensary alone with no apparent trouble, every week in the summer. I think that the condition of the heart was interesting in one way, and that was, that I felt very sure that there was a double lesion of the aortic valves as the murmur was transmitted to the superficial arteries. I think if the murmur had been simply transmitted from the aneurism that the sound would not have been heard in the arteries as in aortic regurgitation, a short, sharp sound. I did not consider that the innominate was affected on the right simply because I did not find any difference in the rate of the pulse in the two wrists. There need not necessarily be any difference if the innominate is affected. Most people consider that rare cases are apt to come together. Within a week after this woman appeared a second case of aneurism came in. I have only the fragmentary notes I took at the time. She was seventy years of age, had acute rheumatic fever seven years ago. Short of breath four years. Good deal of cough. She noticed a beating in her neck five years ago, and she was of the opinion that the beating had not increased. Over the aortic valve there was a double murmur. The heart was much enlarged in area, apparently dilatation and not hypertrophy, as the sounds were weak. In the first portion of the right carotid there was a swelling. Over this tumor there was a murmur and lateral expansion. The superficial veins of the neck and chest were considerably dilated. She came to the Dispensary on account of cough and dyspnoea. The lungs were full of fine rales, apparently oedema secondary to the cardiac trouble, and she was at the time very sick, hardly able to leave her bed. After a time she was able to be about and do her housework. Now she is unable to leave her bed.

DR. F. M. BITTORS said that he saw this first case, and that he had seen a very similar case in one of the London hospitals. The aneurism was single, and they

were attempting to cure it by the pressure of a shot-bag with a hole in the centre over the aneurism. This would seem to be a pretty dangerous thing to do. I should think if the person's general health warranted it, operation would be safer than pressure, especially as any thrombi which might be torn off during that treatment, would go directly to vital centres.

DR. J. A. JEFFRIES: I was interested in what Dr. Jackson said of the patient who came in with headache. In the last eighteen or twenty-four months two patients have come to me, complaining only of headache, which I have not been able to cure; and on careful search in each case I found a small aneurism apparently at the base of the right carotid. On this account it is interesting that there was headache as the principal symptom. One of the two cases I have followed up since, and the growth of the aneurism though gradual is certainly very slow. By measurements I know it has grown a little. If it keeps up this rate it will last a long time.

DR. BLODGETT: I would like to ask the reader if any hope of permanent benefit or relief for distress can be placed in medicinal treatment by means of large doses of iodide of potassium or other remedies, by rest in bed, or any other external method or internal treatment?

DR. TEMPLE: In reading over the history of the treatment of aneurism, I have found various methods of treatment advised and tried, but to my mind without any satisfactory result. The idea of diminishing the diet and increasing the amount of fibrin in the blood in the hope of producing a condition in the sac that would tend to do away with the cavity and fill it with a solid mass, is erroneous, as by that method you reduce your patient and create a condition of anaemia and poor blood, rather than a condition that would favor the occlusion of the aneurism. The treatment by the iodide of potassium applies as much as any treatment if you are going to give anything. It seems to me the treatment should be largely symptomatic and that we must rely more upon the natural treatment than upon iodide of potassium or starvation. About the surgical treatment of aneurism I know but little.

DR. G. W. GALVIN: In a case of aneurism of the innominate, which Dr. Ingalls saw with me last summer, I think there was no difference in the pulse of the two radials. The man was confined to the house only about three weeks before his death. He was a carpenter and had done much hard work.

DR. G. W. GALVIN read a paper on

THE NEED OF AN EMERGENCY HOSPITAL IN THE BUSINESS DISTRICT OF BOSTON.<sup>4</sup>

DR. G. H. M. ROWE: I have been much interested in Dr. Galvin's paper, and in his work at his Emergency Hospital on Kingston Street. Dr. Galvin is entitled to credit for his work in filling what he considers a gap in the South Cove district. The subject of the relations of public health, and the relief offered to it by the public and private hospitals, dispensaries, and various charities of our city, is not brought to the front as often as it might be, in the good interest of all concerned. Generally, the primary impetus given to private relief, comes from private sources, such as a beneficiary fund or legacy. Public relief should come from public sources, and in the special subject under

<sup>3</sup> See page 136 of the Journal.

<sup>4</sup> See page 131 of the Journal.

discussion (emergency hospitals), no class in our community is better informed, and appreciate the needs better than the medical profession. It is therefore, fitting that the medical societies should become mouth-pieces for the expression of the various views held, and recommendations desirable.

It may be interesting to many of the members of the Society to know something of the progress made in other cities in the way of providing emergency hospitals. In New York, previous to the abandonment of the old New York Hospital on Lower Broadway, there was then no emergency hospital in the then down-town portion of that city. When the new hospital was built on 15th Street, the absence of a hospital that could be used for emergencies was much felt. It was a long way from the Battery and the docks to 15th Street. Therefore, owing to the marked demand for places to receive emergency cases, the New York Hospital established a branch on Murray Street, near the City Hall, and which is generally spoken of as the Murray Street Emergency Hospital. The amount of work done there is quite large. The class of cases received is all emergency work,—maternity emergencies excepted. They have thirty beds. I have seen more than twenty cases in the hospital at one time, many of them severe. All classes of surgery, both minor and capital operations, are taken at this hospital, and the patients are transferred to the New York Hospital as soon as it is safe to move them. It is not intended to retain patients there when they can be moved. They have an out-patient service, which is open day and night. Stimulated by this move, the Sisters in charge of St. Vincent's Hospital on the east side, established an Emergency Hospital, which also was a branch of St. Vincent's Hospital. Therefore, in lower New York there are two emergency hospitals; the Murray Street and St. Vincent's. There is still another, located in upper New York, somewhere near 125th Street, but this, I think, was established with special reference to maternity cases.

The city of Buffalo has two emergency hospitals; one is the Fitch Emergency Hospital. The creation of this hospital does not appear to have been from any apparent necessity, but was the outcome of a legacy left by Mr. Fitch for several distinct lines of work in public charity. Amongst other matters, he specified in his legacy that a hospital should be maintained for emergency purposes. The hospital is well arranged, equipped and officered, and does good work. While the Fitch Accident Hospital has no official connection with the Buffalo General Hospital, the people composing the management of each are also officers in the other. In fact, it might be said that the Fitch Accident Hospital is *practically* a branch of the Buffalo Hospital. The Sisters of Charity have also created another hospital, in the immediate vicinity of the Fitch Accident Hospital, where they have accommodations for about twenty patients. This, also, is a feeder for the main hospital.

Brooklyn has an emergency hospital in the southeastern part of the city, amongst the heavy docks, where there are many heavy accidents. This, also, is an adjunct of the Brooklyn City Hospital.

In Philadelphia, I think I am right in saying that there are no emergency hospitals, strictly as such. The various general hospitals are so located and distributed that they are in a good position to take all

emergency cases. Philadelphia may be said to be in about the same position, in this matter, that Boston is.

I intended, before discussing this topic to take a compass and go over a map of the business section of Boston, in order to see what points were farthest removed from any hospital. This I have not time to do. I am under the impression, however, that one and a half or one and three-fourths miles would cover the most extreme point. The distance from any one point to a hospital is not very great, not being more than fifteen to twenty minutes distant at any one point. In my experience, it seems that it is not a question of *distance*, but a question of the *faulty methods in getting patients to a hospital as speedily as it should be done*. In this matter we are open to much greater criticism, than that there is no Emergency Hospital in this portion of the city. Minor accidents and trivial injuries, it seems to me are fairly well taken care of now. In the forenoon there are seven dispensaries, readily reached from the business part of the city, most of which have a surgical out-patient department, where proper cases can be taken care of. At the general hospitals, out-patients are received at any time of day or night. At the City Hospital, we have had this last year more than 1,200 who have come to the hospital outside of the usual hours, when the Surgical Out-Patient Department is open. The Massachusetts General Hospital has a list nearly as large. It therefore seems that a large number of Emergencies are well provided for. In regard to more serious cases, requiring operations, and special treatment; — while the number of beds is sufficient, the facilities for getting patients to the hospitals are not as prompt as they should be. Speaking of the ambulance system in Boston, I should say that the ambulances were sufficient in number, but without proper system. At the City Hospital there are three, either of which can be had by day or night, for proper cases. Four-fifths of the work done by these ambulances is confined to medical cases. The police take care of nearly all surgical cases. The Massachusetts General Hospital has one ambulance; the Police Department has one in East Boston, one at the North End, one at LaGrange Street, one at South Boston, and two at Roxbury. The Marine Hospital in Chelsea has one, but this could not be counted for use in City work. The Health Department has one, specially for small-pox. The City Hospital ambulance may be called to West Roxbury, Orient Heights, East Boston, to Charlestown Neck, or Milton Lower Mills all in the same half day, and for cases which, under the present arrangement, would not be brought to the City Hospital except by one of its own ambulances. The police endeavor that each ambulance shall take care of surgical cases arising within its own district, and ambulances may be sent outside, on the order of the Superintendent of Police.

In New York the system is entirely different. Practically the whole city is distributed into ambulance sections. All hospitals or ambulance stations are directly connected with the police-signal system. Each ambulance has its own section, and covers a well-defined territory. It responds to calls from boxes, each in its own territory, exactly the same as our Fire Department responds to numbered boxes within defined districts. There is no distinction made between a hospital which is a private charity, or the Bellevue, which is supported by the municipality. The Presbyterian, Roosevelt and New York Hospitals all respond

to calls within their own territory. The runs are short, reducing distance, time, and wear and tear. To the best of my knowledge, the New York system of ambulances is not equalled by any city in the world.

In Boston, as I have already pointed out, a severe surgical injury may obtain an ambulance in a fairly reasonable time; nevertheless, it must be confessed that for want of a properly defined system, more time is consumed than is proper, in removing persons from their place of accident to any hospital. Each and every hospital in Boston doing surgical work, should have an ambulance, and the system should be so well organized and defined that any emergency occurring within that district should be sure to receive an ambulance in a reasonably short time. We have to confess, however, that this is not the case, as matters now stand. Ambulances may be reached at the hospitals at any hour and the Police Department through telephone, but verbal telephonic communications, as we all know, are not reliable, and have the demerit of being less sure, and slower than signal calls. This subject of the deficiency of our ambulance system I have on several occasions pointed out. A perfection in our ambulance system would place us on a much better basis, and create better public service than the creation of more emergency stations, without a change in the ambulance system.

In this connection, I desire to call attention to the fact that large numbers of accidents and heavy cases come to the City Hospital from East Boston especially, as well as from Charlestown. East Boston has an ambulance, and being separated from the City proper by a branch of the Harbor, the time taken in getting a patient to the City Hospital is always long, and in many cases has been to the detriment of the patient. If I were asked to point out the section of the city that stands most in need of what might be called an emergency hospital, I should say East Boston *especially*, as well as (to a less extent) Charlestown. South Boston has the Carney Hospital, but the ambulance in that section is under charge of the police.

I think it should be noted that among the conditions under which an emergency hospital is established and managed, this point should be specially considered; whether or not such a hospital should not be directly and officially connected with one of the *general* hospitals. In all emergency hospitals I have previously mentioned, there has existed a direct affiliation, if not a joint management, between each of the emergency hospitals and a larger one. I think it would be an open question whether the management of any large hospital would be willing to receive cases that had previously been cared for, operated upon, or treated at an emergency hospital that was in no way connected with it. Any one connected with our hospitals, knows that the greatest care is needed to avoid attempts to institute claims for damages, through suits and other methods. The staffs of different hospitals vary much in their surgery, and the details of carrying out treatment. In fact, individual members on the same staff are quite as much as do different hospitals from each other. This condition is verified by the fact that when one member of the surgical staff goes off duty he clears the ward of all chronic and unfavorable cases for his successor. I much doubt whether the management of our large General Hospital would systematically admit or continue treatment, surgical cases more or less severe, which had been operated upon elsewhere in

other hospitals, not under their own control. Unhappy results in any such cases mean a *divided responsibility*. General hospitals should so systematize their work that, running the dangers of complaints and suits, they would not have to assume responsibility for the alleged bad work of cases treated in two different places. Therefore, it seems to me that if an emergency hospital is established, it should be an annex, or at least have some direct affiliation with a general hospital. No doubt this very principle has defined the system of the hospitals that I have mentioned in New York and Buffalo.

DR. A. T. CABOT: It seems to me that the hospitals of Boston are peculiarly well distributed, one being far towards the North End, and the other well in the South End, and I should think that Dr. Rowe's estimate of one and a half miles from any point of the city to one of the hospitals, counting the Carney Hospital as filling the gap in South Boston, was a fair estimate. I do think the ambulance system is deficient. I think one addition to the ambulance service, which I believe they have in New York, and which we have at the Massachusetts Hospital at all events, should be a trained assistant to accompany the ambulance to every case, — a man competent to stop hemorrhage, or to put a fractured bone in the best position for transportation. Such an assistant with every ambulance, and with possibly ether and a small chest of splints and dressings, would, I think, enable the transfer of patients from the place of injury at any point in the city to one of the hospitals with as much comfort as the transfer from one part of the hospital to another.

DR. INGALLS: I think it is a consideration devoutly to be thought of, what shall be done with a person when he receives a serious accident in some parts of the city, and I don't know of any solution but this, that one ambulance or more than one should be placed in the business part of the city, so that the ambulance should be at hand in five minutes and take the injured one to some hospital.

DR. NICHOLS: I should like to express my gratification at listening to Dr. Galvin's paper, and it seems to me that the recommendation he has offered ought to appeal with greater force, because it comes from one who has had a very long and extensive experience in this particular line of practice. It occurred to me that there were certain reasons or causes why accidents in the business part of the city were growing more frequent of late years, and are likely to grow still more common in the future. The first is the congested condition of our narrow streets, and this condition becomes marked at a more rapid degree than the increase of population. This is seen in the very great increase in riding in the electric cars. While the city increases five per cent. in population, the increase in this traffic is ten or twelve per cent., and so likewise the increase in the thronging of the streets; and the more crowded the streets, the more the liability of accidents in crossing. Other causes are rapid and reckless driving by irresponsible herd drivers. This has caused a great many accidents, some of them fatal, in the last few years. Then comes the introduction of electric cars in response to the demand for rapid transit. Rapid transit means serious injuries, all of which call for immediate relief. Still another cause might be cited in the very lofty structures that have been put up in the past few years. With the construction of each one of these buildings a

certain number of accidents occur. All these causes, some of which are quite recent, mean a greater frequency of accidents, and it seems to me wise that some additional provision should be made to take care of them. A small room in the basement of the Old State House, or in the building which will take the place of the present Court House, might furnish as good a locality as could be found, but whatever place may be chosen for the locality, I think that we must all agree that the recommendation which Dr. Galvin makes is a wise one.

DR. OTIS: I understand that Dr. Galvin suggests that the location of an Emergency Hospital, if one is needed, about which there seems to be some doubt, and of which I am not convinced in my own mind, should be in the South Cove. I would make the suggestion that already in that vicinity there exists the starting point for an Emergency Hospital of that kind in the present Boston Dispensary. It seems to me if any such establishment is considered necessary, we could with greater ease than start an entirely new one, add in some way or other to the Boston Dispensary. It is an institution which more than pays for itself, and might take on this additional work, and moreover having already an out-patient department for accidents, etc., there might be a limited number of beds attached to the present out-patient department for these emergency cases as in Chambers Street, New York. A good many cases are brought in, in such condition that they require some temporary operation to put them in condition to be moved to the hospital; and those cases need beds in the place where they are operated upon.

DR. E. W. CUSHING: I do not think Boston has developed its ambulance system in the way it might do. In 1870, when I was in Bellevue Hospital, I sent to Dr. Ingalls a description of the ambulance system as used in New York. This was published, with a drawing, in the *Boston Medical and Surgical Journal*. We had six ambulances there, and there were two internes accredited to the ambulance service, and the rest went when it was necessary. If I am not mistaken I have seen the Boston ambulance going for a patient without any physician with it. In New York every police station was in communication telegraphically with the hospital, and the moment an accident occurred it was telegraphed to the nearest hospital, and an ambulance immediately sent out. The suggestion of Dr. Ingalls seems to me a very good one, and it certainly seems as if some of the assistants at the hospitals could be detailed to be with the ambulance, in the day-time at least.

DR. NEWELL: I think it is quite evident from the discussion that something either in the way of an improved system of ambulance service, or an emergency hospital is needed in Boston. There are two points about which I would like to speak; one is the harm caused by delay, especially referred to by Dr. Rowe. I think it is seldom that a case is fatally affected by the ordinary period of delay, but the longer the delay in the ordinary case, the more injury is done. I think one very important point to which especial attention has been given in the last few years abroad as well as here, although not spoken of to-night, is the *early disinfection of the wound*. A great many wounds have an unfavorable progress after entering a hospital, from the fact that they lie a long while unattended to, and a septic process is thus often rendered unavoidable.

DR. ROWE: Whatever view may be taken as to the further necessities of emergency hospitals in the business section of the city, there is no doubt that the ambulance system requires reconstruction. There is a want, however, which is greater than that of either an emergency hospital or a perfected ambulance system, and that is some scheme which shall relieve the various wants felt by all of those who have to do with public relief. Prominent among these stand *alcoholic cases*, whether in the station-house, under arrest, or in any way demanding public relief. Physicians in any way connected with public affairs, know that patients in an alcoholic condition occasionally die in police stations, with or without head or other injury, under circumstances placing the city both liable to damages, and also under the charge of an alleged want of proper care of such cases. Women of the lower classes, or respectable women who are strangers, are occasionally suddenly confined in improper places. *There is no place*, strictly speaking, suitable for such cases. Persons arrested under suspicion of insanity, or persons under arrest who indicate some form of mental aberration, *have not a suitable place* to be taken. The cumbersome methods now upon the statute books, relating to the admission of emergency cases to hospitals for five days' time, practically prevent asylums being used for emergency cases. Dr. Fisher, of the Boston Lunatic Hospital, clearly points this out in one of last reports. The majority of such cases have heretofore been confined in the basement of the Court House, in the so-called Tombs. The Board of Health *has now no place where they can take cases of suspected contagious diseases, particularly small-pox and typhus fever*. These, and other public necessities, should be met on some common basis, supported under the municipal appropriation and management, which, for want of a better name, we might call a "House of Relief." Such a house should be under the charge of the police as to executive work, because the police are called upon to care for nine-tenths of the cases I have named. The medical management should be under charge of the Health Department, by the City Physician, or one of his assistants. This would place such an establishment strictly under the care of the city, both as to executive work and medical attendance. There need be no conflict of authority, since the Police Department assumes the entire control, the medical care and recommendation for care and disposal of patients alone excepted. Could such a *desideratum* be furnished, it would remove many difficulties, diminish many complaints such as have been made in times past, and render a far greater service in public relief than would an Emergency Hospital, practically limited to a single class of cases.

DR. GALVIN in closing, said: I did not mention anything about the hospital ambulances, but simply about the police ambulance. The distance from the business districts to the hospitals is about the same, but there is a difference in time of about fifteen minutes. The route to the City Hospital is almost direct from the Southern railroads, but to get to the Massachusetts Hospital in the middle of the day requires certainly one half-hour. I think the ambulance service could be very much improved upon if the different railroads would provide the service. I mentioned the fact to Mr. Kendrick of the Old Colony, and he was very willing to furnish it, provided the New York and New England, and Boston and Albany

would bear a part of the expense. The New York and New England would if the Boston and Albany would, but the Boston and Albany did not feel like putting in a cent. I think the matter may be brought about by the coöperation of the steam railroads, the West End Street Railway and the large express companies.

Dr. BLODGETT said that the subject of discussion had assumed so important a character that it would be unfortunate if it should be allowed to drop at the present stage, and he therefore moved that a committee be appointed to take into consideration the subject of Dr. Galvin's paper, and also the Condition of the Present Ambulance System of Boston, with such recommendations or suggestions upon the one point and the other as that committee might find expedient or necessary.

The Chairman appointed as a committee to whom the above questions should be submitted: Dr. G. H. M. Rowe, Dr. W. B. McMichael, Dr. A. T. Cabot, Dr. J. H. McCollom, Dr. W. L. Richardson.

Adjourned at 10.15 o'clock.

#### THE NEW YORK ACADEMY OF MEDICINE. SECTION ON GENERAL PRACTICE.

STATED MEETING, January 20, 1891, Dr. FRANCIS DELAFIELD, Chairman.

##### ELECTION OF OFFICERS.

Dr. FRANCIS DELAFIELD was re-elected Chairman, and Dr. CHARLES E. QUIMBY, Secretary, of the Section for the year 1891.

Dr. R. C. M. PAGE read a paper on  
PHTHISIS, ITS CLASSIFICATION, EARLY DIAGNOSIS,  
AND RELATIONS TO CHRONIC PNEUMONIA.

Since the recent discovery of Koch for the treatment of tuberculosis in general, he said, it was perhaps more important than ever that we should have a clear definition of the disease so far as it affected the lungs, as well as a convenient and proper classification of its various forms, its relation to certain similar affections, and, above all, the best means for an early diagnosis. The term phthisis, as now generally understood, signified pulmonary tuberculosis, the germ of which is Koch's tubercle bacillus, and which is infectious under certain conditions. The two grand divisions of the disease were the acute and chronic varieties.

1. Acute phthisis occurred when the progress of disease was rapid. It might appear to commence as a lobar pneumonia, but its true nature soon became evident. Instead of resolution taking place, as usual, there were signs of softening, followed by excavation, rapid emaciation, and death in the course of a few weeks. Various names had been given to such cases; but inasmuch as phthisis was always and necessarily a tubercular disease, it was sufficient to characterize them as acute pneumonic phthisis.

Acute phthisis might also be a part of that form of the disease known as military, general, or disseminated tuberculosis which affects various organs and tissues throughout the body simultaneously. The physical signs of the pulmonary disease in such cases were simply those of bronchitis; the tubercles being disseminated throughout the lung. This disease was nearly always secondary to one pre-existing tubercular lesion, from

which bacilli in large numbers were absorbed into the circulation. The tubercle bacilli did not proliferate readily in the circulating blood, but might be conveyed by it, to a limited extent, even in ordinary cases of chronic phthisis, especially to such organs as the liver, kidneys, spleen and cerebral meninges, in which the local circulation favored their lodgment. In general military tuberculosis, however, the bacilli entered the blood in large numbers, either through the lymphatics — especially the bronchial glands — or by unoccluded veins. All the varieties of acute phthisis mentioned by authors might be reduced to the two principal forms given, acute pneumonic phthisis and acute disseminated phthisis.

II. Chronic phthisis, likewise, had been described under a number of different forms; but these also might all be reduced to two, according to the tissues chiefly involved, namely, catarrhal and fibroid. These two varieties were not always distinctly separate, but might, and often did, exist together in various proportions. Catarrhal phthisis was that chronic form of the disease most commonly met with, and that which usually appeared first at the top of the lungs. The reasons given for its affecting the apices first were as follows: (1) These parts are the most liable to injury from exposure or strain from coughing or lifting, and, according to Green, injury to the vessels from imperfect circulation and stagnations of blood — conditions tending to produce frequent exudations favorable to the lodgment of bacilli. (2) There is less respiratory motion, with consequent imperfect ventilation and less tendency to the absorption of exudations and disturbance of bacilli.

Beginning in the bronchioles, which became plugged with an inflammatory exudation, and usually limited to a circumscribed area, the disease extended down into the air-cells; resembling in this respect catarrhal or lobular pneumonia. It was, in fact, a tuberculous lobular pneumonia, and this was one of the names by which it was known. The walls of the bronchioles became infiltrated with leucocytes and epitheloid cells, as in ordinary inflammation, and in some cases fibrin and even blood, were found. But, besides these, there were tubercles which characterized the disease, distinguishing tubercular inflammations from all others. Having given a description of the tubercle reduced to its ultimate elements, Dr. Page said that it was not according to Williams, to be regarded as an adventitious growth, but simply a hyperplasia of normal tissue caused by tubercle bacilli which had been introduced from without — usually by means of inhalation — and found lodgment in a favorable soil. These tubercles were also primarily similar, if not identical, in all forms of the disease and whatever locality found; differing chiefly in color and consistency, according to their age and changes they had undergone. So-called scrofula, it was now well-known, was nothing more than tuberculosis of the lymphatics.

As the disease progressed there soon occurred caseous metamorphosis of the tubercles and other products mentioned, together with necrosis of the delicate tissues involved; resolution being impossible. Softening of this caseous material led to the formation of cavities, partly by absorption, but chiefly by expulsion in coughing. The bacilli were found chiefly in the softened contents and on the walls of the cavities, but might also exist in all the affected tissues. In some cases the cavities became closed, owing to arrest of the dis-

ease, and a cicatrix was left. In others, becoming firmly enclosed by connective tissue, their contents cretified. In the majority of cases, however, as was too well-known, the disease progressed and the patients died. In speaking of the mode of extension in this form of phthisis, he said, that the vessels were usually occluded in the ulcerative process, so that it could not spread by absorption into the blood, except under the circumstances before mentioned. It had no predilection for the lymphatics, like fibroid phthisis, but it extended along the air-passages from one point to another, as well as by imperfect virus being sucked back, during inhalation, into parts as yet unaffected.

Intestinal ulcerations were also likely to be formed by the swallowing of virus, and they occurred in about one-half the number of cases both of catarrhal and fibroid phthisis. Owing to the presence of gastric juice ulceration of the stomach did not occur except in extreme cases of emaciation; the virus more readily finding a lodgment in the region of the ileo-caecal valve, the large intestine, and sigmoid flexure. The mesenteric glands and peritoneum then became affected secondarily by absorption. Laryngeal phthisis, spoken of by some authors, was simply tuberculous laryngitis, which was probably always coincident with tuberculosis of the lungs.

The second form of the chronic disease, fibroid phthisis, also began, according to Coats, in the bronchioles; but it extended not by the air-passages, but along the lymphatics to the peri-bronchial, interlobular and sub-plural connective tissue. In very rare instances extension in reverse order occurred from a tuberculous pleuritis. In other words, fibroid phthisis was a tuberculous interstitial pneumonia, and, like chronic interstitial pneumonia, it led to bronchiectasis and shrinkage. Very few bacilli — sometimes none at all — were to be found in the lung tissue; these chiefly existing in the sputa and on the walls of the bronchiectatic cavities. As to the relation between chronic interstitial pneumonia and fibroid phthisis, Dr. Page said that before the discovery of the Koch bacillus they were regarded as the same disease. After this, however, the two affections were separated, and great care was taken to separate them; but during the recent Berlin Congress they were again considered to be one, and the same disease — always a tuberculous one. Even in cases of potter's lung, knife-grinder's consumption and other forms of pneumonokoniosis the tubercle bacillus, according to Williams, was nearly always found.

In chronic phthisis of either form the prognosis depended much on an early diagnosis. As to the earliest signs by which the disease could be recognized, if the top of the left lung were affected, it was much easier to make an early diagnosis than if the trouble were on the right side, since in health there existed on the right side exaggerated fremitus and pectorophony, as well as slight dulness on percussion and rude respiration — from signs of incomplete consolidation met with in incipient phthisis, if occurring on the left side. In addition to these, therefore, some localized adventitious sound was necessary, and as chronic phthisis of either form usually began as a localized tuberculous capillary bronchitis, the first adventitious sound heard was usually the subcrepitant rale. Any localized adventitious sound, in a suspicious case, would, however, aid in the diagnosis of phthisis. Frequency of the pulse and loss of appetite were

among the earliest general symptoms. Of course, hæmoptysis, if it were not explained by the presence of heart disease or other cause, would be almost conclusive.

The question naturally arose, Shall we rely only upon finding the bacillus? Of course, if the bacillus were found, it would be conclusive. But did we find it before the subcrepitant rale was heard, and were we to wait until it was found before we were justified in resorting to improved methods of treatment, involving perhaps the sending of the patient away from his business. The cough of chronic phthisis was at first dry and hacking. Expectoration was scant, and what sputum there was did not contain bacilli, unless in very exceptional cases, because the bacilli were not yet liberated. Examination of the larynx had been claimed as the best method of arriving at an early diagnosis; but, as already stated, primary tuberculous laryngitis was rare, and by the time the disease was apparent there it would already have been recognized in the lungs.

In speaking of Koch's "lymph" Dr. Page said, in conclusion, that time had not yet elapsed sufficient to determine the real value of this reputed discovery. But even if all that could be claimed for it should be true, the importance of an early diagnosis and the prompt application of the remedy was evident; for when loss of important tissue and disease of other organs had occurred, through ulceration and other processes, there still remained pressing considerations regarding treatment, even after the bacillus had been driven from the field.

DR. W. P. NORTHROP read a paper on

#### TUBERCULOSIS IN CHILDREN: PRIMARY INFECTION IN THE BRONCHIAL LYMPH NODES.

He said that the object of the paper was to illustrate and strengthen the theory put forth in the title. In the New York Foundling Asylum the records of 125 post-mortems in cases of general tuberculosis in which the details were sufficiently clear to classify them carefully for the purposes of the paper, furnished the following analysis:

(1) Thirty-four indeterminate cases, in which the lesions were so extensive involving the organs of the thoracic and somatic cavities, bronchial lymph nodes, mesenteric as well, that the point of primary infection could not be determined.

(2) Twenty cases of bronchial node infection; cheesy masses in lungs; general tuberculosis.

(3) Forty-two cases in which only cheesy masses were in the bronchial lymph-nodes; general tuberculosis.

(4) Thirteen cases in which the bronchial nodes were cheesy; the only other tubercles in the body being discrete miliary bodies in the lungs.

(5) Thirteen cases in which all the tubercles of the body were in the bronchial nodes.

The following case was given in illustration: A female three years old; sick six days — measles; diphtheria; croup; intubation; pneumonia; death. At the autopsy tubercles of the bronchial lymph-nodes were found. A half-dozen nodes about the roots of the lungs were enlarged, and exhibited gradations from cheesy masses to discrete tubercles. Bacilli were present in moderate number. The lungs presented the ordinary picture of extensive descending diphtheria and pneumonia. There were no tubercles in

them. This case was regarded as most illustrative. The duration of the illness was so brief (six days), and the lesion was sufficiently advanced (certain nodes being quite transformed into cheesy material) to fairly allow the presumption that this well-nourished child was thriving very well until it succumbed to the overwhelming infection of measles and diphtheria.

(6) A group of three cases standing out in the 125 in which the primary infection was obviously in the mesenteric nodes.

The cases of Drs. H. P. Loomis and Ira Van Giesen were cited in confirmation of the theory. Dr. Loomis tested the bronchial glands of forty-eight persons, dying from accident or acute disease, by triturating the glands in distilled water and injecting the mixture in the pleura of rabbits. The rabbits were subsequently killed, and, in case of their presenting appearances of tuberculosis, the nature of the lesions was still further tested by inoculating other rabbits from them. Only in case of the success of inoculations of this second series was it assumed that the glands used for the first inoculations were tuberculous. In none of the cases used for inoculation were tubercles found in any other organs than the bronchial glands. Eighteen of the rabbits inoculated died too soon to determine as to the success of the inoculation; but of the remaining thirty, eight developed the lesions of tuberculosis, the character of which was confirmed by the success of inoculations on other rabbits. In five of the successful cases death occurred suddenly from accident, while the persons were in apparent health. In three of the cases giving negative results calcareous nodules, and in two others cheesy masses, were found in the bronchial glands, and the failure of the inoculation experiments in these cases was thought to show that the bacilli, in case they had even been present, had died. These experiments seemed to show the possibility of the infection of tubercle remaining latent in the bronchial glands for an indefinite period.

Dr. Northrup inquired if there were any physiological experiments which throw light on this question of infection through the bronchial nodes, and by way of answer quoted some conclusions of Julius Arnold after dust inhalations in animals, showing how dust (ultramarine) was found in the bronchial lymph-nodes (glands) three hours after inhalation; also in what parts of the air-passages the dust was mostly found, and how disposed of after suspension of the inhalation for some time. The writer confessed to have found great satisfaction in the explanations afforded by these animal experiments. Dust-particles were repeatedly found embedded in the walls of the alveoli, in the lymph-canals and the afferent vessels, forming a continuous chain of evidence as to the course travelled by the particles. No dust was ever found in the vessels leading from the nodes; such filter-nodes apparently having the power of collecting and retaining for a very long time the dust-particles brought to them.

Experiments by Dobrovolnsky and Kassakowicz were quoted to show that bacilli can pass through the mucous membranes and develop their brood in the lymph nodes without showing any trace of the point of their entrance.

A summary of the one hundred and twenty-five cases of general tuberculosis at the New York Infant Asylum was given as follows:

Eighty-eight were of primary bronchial node infec-

tion; three were of mesenteric node infection, and thirty-four were indeterminate. Nine cases were added from Drs. VanGiesen and Loomis.

Dr. Northrup believed that in such cases the inoculation cure of Dr. Koch gave hope of its greatest achievement. This latent tuberculosis, he thought, might easily account for some of the accidental temperature experienced in inoculation.

Dr. J. WEST ROOSEVELT said Dr. Northrup's paper was particularly interesting as pointing out the methods of tubercular infection in children. As far as he himself had been able to judge, in adults quite as frequently as in children, the primary infection was in the bronchial lymph nodes. It seemed to him that it was high time that we should give up the idea of infection being caused by direct inhalation of tubercle bacilli. There was no evidence whatever, capable of explaining the existence of tuberculosis in the lung, except as depending primarily on infection of the bronchial glands or other part of the lymphatic system. Infection by *indirect* inhalation, as described by Dr. Northrup in his paper, appeared to him to be the most rational explanation of the disease in all cases of pulmonary tuberculosis.

The probable course of events was somewhat as follows: The bacilli, after being inhaled, were arrested by the lymph glands, which became tubercular. After a time cheesy masses from these glands passed through the thoracic duct, either from the right or the left side, and thence into the vena cava. They thus found a lodgment in the lungs, preferably in the upper lobes, and generally near the pleural surfaces. In a paper which he had read before the Section a month previous he had endeavored to show how impossible it was to satisfactorily explain the ordinary situation of early tuberculous deposits in the lungs on the theory of direct inhalation. The lungs were practically a filter, in which we would particularly expect any materials introduced through the venous system to be gathered up. It was thus that they gathered up tubercle bacilli and also masses of pigment. In conclusion, Dr. Roosevelt spoke of gastro-intestinal tubercular infection and of the danger that on this account arose from the ingestion of milk or other food containing bacilli.

Dr. Wm. H. THOMSON remarked that for a long time past it had seemed to him that on account of the frequency of early tuberculosis in the upper lobes of the lungs there must be some connection between this and the bronchial glands. He had, however, looked upon the matter merely from a theoretical point of view, but it was now easy to understand the relation which these glands bore to infection of the apex of the lung. Signs of the very early implication of the bronchial glands, he said, were not infrequent in the phthisis of adults. One of his first cases of the kind was in a gentleman about forty years of age, who, with a slight cough and dulness at the right apex, was soon troubled with severe dyspeptic symptoms, and then with intractable vomiting. Great hyperaesthesia of the pharynx then supervened, and soon complete aphonia, which could not be accounted for by the appearance of the vocal cords, which were but slightly congested and which were never ulcerated. Between the scapulae, however, the bronchial breath sounds were much exaggerated, and Dr. Thomson pronounced his gastro-laryngeal symptoms as most likely due to enlarged bronchial glands pressing upon the pneumo-

gastrics, and that in time he would regain his voice by the softening of these indurated glandular masses. His voice perfectly and rather rapidly recovered twenty-two months afterwards, and his gastric troubles simultaneously improved; but soon after this he developed a most agonizing sciatica in both legs, which proved to be due to the formation of a psoas abscess, to which he ultimately succumbed.

Since that time Dr. Thomson has met with several cases of similar vomiting before the formation of vomicae in the lungs, occasionally accompanied with palpitation of the heart and laryngeal symptoms, both in private and in hospital practice, and he had accordingly prescribed in his college lectures that the most effective means for controlling early vomiting in phthisis is repeated dry cupping between the scapulae.

The CHAIRMAN said that as regards one point brought forward in Dr. Page's paper, the matter of tuberculous inflammation, it had seemed to him that altogether the simplest way of regarding it was to always think of it as inflammation attended with the presence and growth of tubercle bacilli, whatever other characteristics it might have. The form of the inflammation varied very greatly in different cases, but the tubercle bacillus was always a constant factor. This was seen even in very small foci of tuberculous inflammation, such as the so-called miliary tuberculosis, when, with the very simplest elements, we always had the bacillus.

The paper of Dr. Northrup, he thought, was one of those fortunate productions brought forward at a time when it would be generally regarded as convincing, because the general tendency of thought had been in the direction indicated, and everybody was willing to be convinced. He thought that of late years all our tubercular studies had been tending in this direction. Whether the bacilli were inhaled or swallowed, they were unquestionably liable to make their way first to the lymphatic glands, and this was, therefore, the primary infection. Hence, Dr. Northrup's argument was all the more convincing because one's mind was already prepared to accept it.

THE STUDY OF MEDICINE IN THIBET. — The Buddhist Lamas' University, in the Transbaikal Province of Thibet, has a medical course of ten years. According to *Nature*, a traveller named Puitsyn has returned from that country with a collection of medical books and drugs illustrative of the knowledge and the methods of practice in Thibet. Mr. Puitsyn remarks that he has found over one hundred diseases described in the Buddhist literature, and of these a mythical origin is ascribed to only two. Strictly medical subjects are not studied until the fifth year of the course, the first four years being devoted to the study of the languages and theology. The eighth year is devoted to astrology, and philosophy is studied in the last two years.

*She.* — Please make me up a dose of castor oil.

*Smart Clerk* (after a lapse of five minutes). — Have a glass of soda, won't you?

*She* drinks soda and waits for the oil.

*Smart Clerk* — Anything else, Miss?

*She.* — The castor oil, please.

*Smart Clerk.* — Why, I put the oil in the soda.

*She.* — Well, I did n't want it for myself. It was for my brother. — *Life.*

THE BOSTON

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 5, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

## THIRD REPORT OF THE ROYAL COMMISSION ON VACCINATION.

IN this JOURNAL (Vol. CXXI., p. 564), we noticed the appointment of a Royal Commission on Vaccination, and the weekly sessions of this body, which has now published three reports. The Commission, which has not yet completed its work, consists of fifteen persons, part of whom hold favorable views on vaccination, and part are known as anti-vaccinationists.

The third Report, which has been lately published is regarded as the most important of all, as it contains the evidence of three witnesses who are, perhaps, the most conspicuous opponents of vaccination. Four sessions of the Commission were occupied with the argument and statistics of Alfred Russel Wallace, who was chosen as the leading exponent of the views held by his colleagues.

According to the *Lancet's* report, the veteran scientist, who had made elaborate preparation, was made to appear to no little disadvantage when his voluminous statistics were subjected to criticism: "He was convicted of a series of blunders that would hardly have been expected of a schoolboy." The statistics as to one French department were recorded twice over. The witness had entered that there were no small-pox deaths in the department of the Sarthe, during a long series of years, whereas in the single town of Le Mans, in that department, no less than 1,179 such deaths had been recorded in two out of the years in question. Wherever, owing to the difficulties attendant on the Franco-German war, no official returns could be obtained, and a blank was left, Dr. Wallace had taken upon himself to make an entry to the effect that no deaths had occurred, and this for the very years when small-pox was most fatally prevalent. "Again and again was the witness taxed with inaccuracies of this and an allied sort, and the feelings which were elicited by the fact of his having submitted such evidence to the Commission may be judged of by Lord John Herschell's retort on one occasion to the effect that, 'one does not accept statistics blindfold'; by Sir William Savory's question, Whether the wit-

ness would like his table to go forth as worthy of his scientific reputation, and by a string of questions put by Sir Guyer Hunter, ending in a demand whether Dr. Wallace regarded the data which he had brought before the Commission 'as having the accuracy of a Darwin or a Tyndall'? Happily, after some hours of discussion, Dr. Wallace was constrained to admit 'that the whole thing is valueless,' and he even refused to respond to Dr. Collins's suggestion that some remnant of good might yet have been found in his tables."

In regard to the evidence, from modern statistics, of the enormous diminution of small-pox in children, namely, in the years immediately following vaccination, Dr. Wallace had nothing whatever to say. Modern statistics emanating from Great Britain; and which can be at once verified, were avoided, while returns for a past century and for distant places, the verification of which is well-nigh impossible, were set out instead, the story being preceded by a glowing account as to their scientific accuracy and importance, which the result showed to be altogether unwarranted.

The *Lancet* sums up its estimate of Dr. Wallace's statistics and arguments by the remark that: "if this is all that science can do for the anti-vaccinationists, the scientific value of the operation stands more than ever confirmed."

#### VITAL STATISTICS OF THE JEWS.

In connection with the Eleventh Census a special inquiry into the vital statistics of the Jews in the United States was made under the direction of Dr. John S. Billings.<sup>1</sup> Returns were received from 10,618 Jewish families, including 60,630 persons. These were on the average above the general Jewish population as to social position, health and vitality. A little over one-third of the whole, are reported as keeping no servants, while the remainder, kept one or more servants, and may, therefore, be presumed to have been in easy circumstances, but it is somewhat remarkable that the average death and birth rates were somewhat less in the poorer classes than among those keeping servants. The proportion of males to females was somewhat larger than in the general population, being 109.53 males to each 100 females. Among the males the proportion engaged in occupations connected with commerce is very large.

The marriage-rate is very low — only 7.4 per 1,000 annually, while in Massachusetts the average from 1855 to 1888 was 18.9. The average age at marriage is greater among the Jews than it is among other people. The low marriage-rate and the increased average age at marriage are the main causes of the low birth-rate. The average number of children born to each mother was 1.66, the greatest proportion being 3.63 for Russian and Polish mothers, and the least, 3.56, among mothers born in the United States. The figures, for successive years indicate that the birth-rate is tending to diminish, while the death-rate seems to be

increasing. The birth-rate among Jews is decidedly lower than it is among the average population. The proportion of the births occurring in December and January and June is found to be decidedly greater than it is for the other months. The explanation of the large preponderance of conceptions in April and in September, is that the Jewish holidays of the Passover and of the New Year occur in those periods.

The proportion of deaths among Jews was less by one-third for males, and less by one-fourth for females, of what it was among our average population. From phthisis and other forms of tubercular disease, the lower death-rate of the Jews is well marked. On the other hand, the Jews appear to be more affected by diseases of the nervous system, and especially of the spinal cord, and by diabetes, by diseases of the heart and great vessels, of the digestive system, of the urinary organs, and of the skin than their neighbors. The death-rate of Jewish lawyers from consumption is over five times greater than the average death-rate from this cause among these people. Jewish physicians are twice as liable to fatal diseases of the nervous system as are other Jews. The cigar-makers and tobacco-dealers are especially liable to consumption, to diabetes, to diseases of the nervous system, and to diseases of the heart. Physicians and bankers have relatively heavy death-rates from Bright's disease.

As regards cancer and malignant tumors, we find that the deaths from these causes among the Hebrews occur in about the same proportion to deaths from other diseases as they do in the average population. But as the ratio of deaths to population is less among the Jews, so the ratio of deaths from malignant diseases to population is also less. Among the living population the proportion found affected with cancer among the Jews was 6.48 per 1,000, while of those reported sick by the United States census of 1880 for the general population, the proportion was 10.01 per 1,000.

Dr. Billings concludes that upon the whole, it appears that we must conclude that those Jews who have been in the United States for more than five years have a decidedly lower death-rate and greater longevity than the people of the same class by whom they are surrounded, and that this greater longevity, together with certain peculiarities of immunity as regards some diseases and excessive liability to others, is in part due to hereditary peculiarities or race characteristics, and in part to their somewhat isolated and peculiar modes of life. With prolonged residence in the United States their death-rate is increasing. In past ages the Jews have shown that they can resist adversity, but whether they can also withstand the influences of wealth and freedom, and retain the modes of life which have heretofore given them length of days, remains to be seen.

There are now a little over 7,000,000 persons in the world who may properly be called "Jews," and of these about 500,000 are living in this country. More than one-third of these last have arrived as immigrants

<sup>1</sup> *General Bulletin*, No. 14, and *North American Review*, January, 1891.

from foreign lands within the last ten years, over 120,000 having arrived at the port of New York alone during the five years 1885-89.

#### ANNUAL REPORT OF THE NEW YORK STATE COMMISSION IN LUNACY.

THE State Commission in Lunacy has sent to the Legislature its second annual Report. In it is stated that the whole number of insane persons in custody in the State on October 1, 1890, was 16,002, that the whole number of asylums, public and private, is 30, and that these institutions represent a total cost of \$16,291,600. The total receipts from every source are \$3,151,000, and a total of 2,707 persons were employed in the care of the insane. The various hospitals and asylums are reported to be doing their work well, and their managers manifest a disposition to co-operate with the commission in making suggested improvements. There are eight State hospitals for the insane, including the present asylum for insane criminals at Auburn, which will be available for general purposes, as soon as the new asylum for insane criminals near Fishkill is completed. The total cost of the State hospitals at the close of the last fiscal year was \$8,889,130, and the capacity of these institutions is, in round numbers, for 6,000 patients; thus making the cost to the State per capita about \$1,500. The employees in the State hospitals number 1,369, and the expense of maintenance last year was \$1,105,987.

The Report outlines the history of the State's system of caring for its insane dependents, and shows that the present plan of management is in accord with the policy that has been adopted for the prisons, and other larger interests that require appropriations by the Legislature. To obtain the greatest benefit from the policy entered upon by the creation of this Commission, however, some amendments to the law providing for its appointment and maintenance are deemed requisite, and those suggested are all in the direction of greater uniformity and concentration. Some changes in the matter of trustees for the various hospitals are recommended, and it is urged that the State Commissioner in Lunacy should be the sole medium of communication between the hospitals and the Legislature, while reports should be made to the Commission, instead of to the Legislature, as at present. The Commission has taken steps to bring the State hospitals into uniformity, in several particulars, in which it has authority under the present law, and it is its aim to make as uniform as possible the systems of general management and internal government in all of them.

Under the head of the Curability of the Insane, the percentages of recovery for the following State hospitals are given: Utica Hospital, 19.53; Buffalo Hospital, 29.19; Middletown Hospital, 18.16; Poughkeepsie Hospital, 18.00; Asylum for Insane Criminals, 3.96.

Whether insanity is on the increase or decrease in proportion to the population of the State the report does not assume to speak from trustworthy data, but

the opinion is expressed, based on the best obtainable information, that it is decreasing. The Commissioners say that something definite about this matter will be known when they have brought the entire insane service of the State into a more harmonious system.

A bill has just been introduced into the Legislature making an appropriation for the establishment of a colony of epileptics and epileptic insane. A Commission is to be appointed by the Governor to carry out the provisions of the measure, which are similar to those of the act establishing State care for the insane poor; the idea being to have victims of epilepsy transferred to this institution from the various county poor-houses and asylums.

#### PAROTIDITIS FROM PNEUMOCOCCI.

IN a recent lecture at the Charity Hospital, M. Duplay described a case of parotiditis following an attack of pneumonia. The patient, a man aged forty-seven, had recovered from his pneumonia, when suddenly there appeared an enormous swelling of the left parotid region; this swelling was painful, was attended with fever, and was followed by suppuration. A marked symptom and one that is regarded as pathognomonic, was the early flow of pus by Steno's duct; subsequently external openings formed in the neighborhood of the ear by the bursting of glandular lobules.

The pus was examined and was found to contain the characteristic pneumococci; inoculated in mice it caused their speedy death, and the spleen and liver of these animals were found stuffed with the same micro-organisms.

The theory which was advanced was that the pathogenic microbe in question had gained the parotid gland by way of Steno's duct, passing thither from the mouth. The micro-organisms are naturally inoffensive, occupying the mouth and pervading the saliva. In states of prostration — such as are readily induced by exposure to cold and other causes — the pneumococci penetrate the organism and light upon an organ, like the lung, which has become enfeebled, and falls an easy prey to the spoiler. The microbe may simultaneously or successively invade other regions, as the middle ear by the Eustachian tube, and cause a pneumococcus-otitis; it may find its way to the frontal sinus and cause a troublesome coryza, or to the parotid gland by Steno's duct, and set up a suppurative inflammation; the condition being that the gland shall be a *locus minoris resistentie* at the time of the invasion.

These parotidites invariably suppurate, and the suppuration is often profound and obstinate; it is a frequent thing to see "fuses" of matter extend under the aponeuroses of the neck, and reach the mediastinum; at other times, they gain the pharynx and give rise to a variety of retro-pharyngeal abscess; other results of these deep suppurations are thromboses of the jugulars, fatal hemorrhages from ulceration of large arteries, and destruction of the facial nerves. Death may also take place from pyæmia or from

propagation of the inflammation to the middle ear and cranial cavity. It will be seen that the prognosis is grave, though mild antiseptics may do much to lessen the chances of death, at least from pyæmia. In the treatment of this affection (which seldom or never undergoes resolution), the question arises whether it is better to make early free incisions, or to wait, and open the purulent foci as fast as they form. Duplay insists that parotiditis may take on two principal forms: sometimes it is a canalicular parotiditis in which each glandular lobule suppurates separately and successively. What is the use, then, he asks, to make early large incisions in such cases? The better way would be to apply emollients and to wait the formation of foci of pus, which are to be opened as soon as fluctuation is detected. At other times it is chiefly the periglandular cellular tissue which is affected; here we find ourselves in presence of a sort of diffuse phlegmon of the region, capable of causing destruction by gangrene, and other grave disorders. Here there need be no hesitation, and free incisions should be early made.

#### MEDICAL NOTES.

THE LETSOMIAN LECTURES on "Anæmia, its Pathology, Symptoms and Treatment," were delivered before the Medical Society of London, by Stephen Mackenzie, M.D., F.R.C.P.

DR. KOCH'S REPORT.—It is reported, again by cable, that Dr. Koch acknowledges he has not yet published sufficient details of the preparation of his fluid to enable any one to make it. He is about to start for Egypt for a vacation of several weeks.

DEATHS AFTER TREATMENT BY KOCH'S METHOD.—The patient in New Haven who was the first in America to receive treatment by the new method has died. A death after treatment is also reported from Bellevue Hospital, New York. Both of these cases were suffering from advanced phthisis, but were personally anxious to have the treatment.

THE GOAT'S-BLOOD CURE.—It is reported that much interest is manifested in Paris in regard to the goat's-blood cure for tuberculosis, advocated by Bertin and Picq of the Nantes faculty. They have injected goat's blood into different patients, and now assert that cures can be brought about by renewing such injections every ten days.

A LOW ESTIMATE OF EDITORIAL ARTICLES.—A comment which we had in mind, but had not as yet put into print, appears in the last issue of the *New York Medical Journal*, which says: The *Medical News*, of Philadelphia, in its issue for January 17th, announces that its editorial pages will not hereafter be regularly used for editorial writing, but be given up to selections from foreign medical literature, but "without the laborious verbosity of the French and German writers." The *News* says that that space "is often an excuse for foisting upon a subscriber much useless material, and for this reason the pages usually so

employed" [the *Italics* are ours] "in the past in the *News* will be taken up with notes on current literature." That this is conscientiously stated there can be no doubt, but, viewed as an arraignment of the utility of editorial writings, regularly and constantly worked up, there is large room for difference of opinion.

OFFICIAL EXPERIMENTS WITH THE KOCH LYMPH.—The following instructions were issued by the Surgeon-General of the Marine-Hospital Bureau, January 19th, to Assistant-Surgeon H. D. Geddings: You are hereby placed on temporary duty at the port of Georgetown, D. C., for the purpose of making experiments as to the efficiency, or otherwise, of the recently invented "lymph" for the cure of tuberculosis, by Professor Koch, of Berlin, a supply of which is herewith transmitted. Your method of making the test will be as follows: (1) You will take a photograph of each patient, and the bacilli will also be photomicrographed. (2) The weight and chest expansion will be recorded. (3) You will ascertain the area of dulness on the chest by means of the pleximetre, and mark its limits with iodine, and photograph the chest. (4) The usual clinical record will be kept throughout, commencing from the time of entering the hospital, particularly observing the time of rising of the evening hectic and its duration, and the time of appearance of perspiration. Its relative amount and duration will also be noted. The temperature will be taken at 7 A. M., between 1 and 2 P. M., and 7.30 P. M. Clinical charts similar to those used in the investigations and diagnosis of yellow fever by Dr. Guitéras and Dr. Faget will be used. The time of administration of the lymph will also be noted. The time of appearance of pyrexia, commonly termed "reaction," and of its disappearance, will also be noted. Besides the foregoing, any other clinical symptoms that may occur to you in the progress of the case will be noted. The sputum cups will be labelled for each patient under observation, and the nurse will be cautioned about allowing them to become mixed in any way. The new pattern paper cups will be used. . . . These experiments must necessarily be private, so that the patients may not be disturbed, but all results will be made public at the conclusion, by this Bureau.

MEDICAL EXAMINERS.—It is unfortunate that different States should have adopted the same term to express entirely different offices. When the office of Coroner was abolished in Massachusetts in 1877, the legal medical officer created to take his place was, and still is, known as Medical Examiner. Several other States have passed statutes regulating the practice of medicine and creating boards of so-called Medical Examiners, whose duty consists in examining candidates for registration. This similarity of terms has been the cause of some confusion, and is likely to be so even more in the future.

UNIQUE JUDICIAL DECISION.—A case unique in the annals of litigation was decided in Ireland last week. A lady who was among the survivors of

the disastrous Armagh railway accident, and received £800 damages for the injuries she sustained, brought further action against the railway company in respect to her infant, which was born prematurely after the accident, and so malformed that it will probably be an incumbrance for life. The judges held that the company had entered into no contract to carry the unborn babe. They had issued no ticket for it, and had no knowledge of its being on the train.

**LARIXOLIN.**—A German patent has been issued for a compound named larixolin, which is alleged to be a perfect imitation of French oil of turpentine. It is described as consisting of a mixture in definite proportions of petroleum and camphor oil, and is alleged to not only have nearly exactly the same odor as oil of turpentine, but to be a mixture of hydro-carbons of the turpene series almost identical with the terebinthine of French oil of turpentine. Larixolin is said to be applicable for all the purposes for which turpentine oil is used.

**PRESERVATION OF DEAD BODIES.**—A French physician, Dr. Variot, has recently perfected a method of preserving dead bodies by galvanoplasty. To facilitate adherence of the metallic deposit he paints the skin with a concentrated solution of nitrate of silver, and reduces this with vapors of white phosphorus dissolved in sulphide of carbon, the skin being thus rendered dark and shiny. The body is then ready for the electric bath, which is served by a thermo-electric battery, giving a regular adherent deposit of copper if the current is properly regulated. With a layer of one-half to three-quarters of a millimetre the envelope is solid enough to resist pressure or shock. Dr. Variot further incinerates the metallic mummy, leaving holes for the escape of gases. The corpse disappears, and a faithful image, or rather statue, remains.

#### BOSTON AND NEW ENGLAND.

**A MAGAZINE FOR THE BLIND.**—The Alumni Association of the Perkins Institute have started this year a monthly magazine in the interest of the blind. It is called "The Mentor."

**MEDICAL EXAMINERS TO BE APPOINTED.**—Governor Russell will have the appointment of about forty medical examiners for a seven years' term. The whole number of medical examiners in the State is seventy-three, but there are several who hold over. Under the law of 1877, the terms of a majority of the present incumbents expire this year by limitation.

**LEGACIES TO VARIOUS INSTITUTIONS.**—The will of Mrs. Walter Baker contains among others the following bequests: To the Perkins Institution for the Blind, Church Home for Orphans, and Consumptives' Home, Boston, \$5,000 each; The New England Hospital for Women and Children, \$4,000; The Free Hospital for Women, Boston, \$3,000; The Home for Incurables, Boston, and Massachusetts Home for Intemperate Women, \$2,000 each. By the will of J. Huntington Wolcott, the President and Fellows of Harvard College, receive \$30,000, \$25,000 being for

the general purposes of the college, and among the contingent bequests, legacies to the Massachusetts Charitable Eye and Ear Infirmary, Boston Dispensary and Massachusetts General Hospital. By the will of W. L. Wilcox, the Springfield City Hospital receives \$5,000.

**HOSPITAL AT BANGOR.**—A charter has been asked for the Eastern Maine General Hospital at Bangor. The form proposed provides that the hospital shall be under the direction and management of nine trustees, six of whom shall be chosen by the corporation and the other three by a board of visitors, which shall consist of the governor of the State, the president of the Senate and Speaker of the House. There are forty incorporators.

#### NEW YORK.

**ITALIAN HOME.**—The new Italian Home on Second Avenue was opened with public exercises on January 26th. The President, Signor Cantoni, and Count Riva, Consul-General of Italy at New York, were escorted to the assembly room on the first floor, by the different Italian societies of the city, and were enthusiastically greeted by a large audience; after which several addresses were made. The establishment includes a hospital, a relief bureau for the poor, a bureau for the protection of immigrants, and a school for Italian children, and there is a four-story building fronting on the Avenue, with a two-story annex in the rear. The hospital department contains several small wards on each floor, which are fitted up in a very complete manner, and it is capable of accommodating ninety patients.

**MORTALITY FROM PULMONARY DISEASES.**—The very large proportionate mortality from pulmonary diseases at this season of the year is shown by the fact that out of a total of 748 deaths occurring in the city of New York during the week ending January 24th, no less than 105 were from pneumonia and 111 from phthisis.

**SCARLET FEVER AT A SCHOOL.**—St. Paul's school for boys at Garden City, L. I., has been closed on account of the death of one of the students from scarlet fever, and the taking down of three others with the same disease. There were one hundred and thirty pupils at the school at the time the scarlet fever appeared, and it was deemed best to send the boys, with the exception of the three ill ones, to their homes as promptly as possible.

**LECTURES ON ORTHOPEDIC SURGERY.**—The Trustees of the New York Orthopaedic Dispensary and Hospital announce that Dr. Newton M. Shaffer will give his annual course of lectures on Orthopaedic Surgery, (free to medical practitioners and students), at the institution on Tuesday and Friday afternoons, from February 3d to March 10th.

On January 29th, the receipts from the Annual Hospital Saturday and Sunday collection amounted to \$54,455.

## Miscellany.

### COCOA-NUT OIL AS AN ANTHELMINTIC.

DR. PARISI,<sup>1</sup> of Athens has communicated to the French medical papers his experience with cocoa-nut oil as a tapeworm remedy. As he was travelling in Abyssinia, one day, after eating and drinking the pulp and milk of several cocoa-nuts, he felt quite sick. Soon he had a passage, and was astonished to notice he had expelled a complete tapeworm, head and all, quite dead. On his return to Athens he repeated the experiment on a number of patients, and was successful in all cases; the tænia always coming out entire and dead. The treatment he has adopted as most convenient is as follows: The patient, while fasting, is to take in the morning the milk and pulp of one cocoa-nut. No cathartic is needed, and no particular care necessary. This simple remedy is as efficient as pomegranate-root or male fern, and, for several reasons, preferable to them.

### CETRARIN.

ROBERT<sup>2</sup> has recently contested the statement that cetrarin, the active principle of Iceland moss, produces an increase in the blood-pressure, while further, his experiments on a large number of animals have shown that this remedy increases the peristaltic movements of the intestines, and is therefore of value in the treatment of chronic constipation. It further is stated to increase the number of the red and the white blood-corpuscles, especially when they have been reduced below normal in various chronic diseases, while, finally, it is a mild stimulant to the central nervous system. It would appear from these facts that the employment of cetrarin is indicated in chlorotic individuals in whom there is loss of appetite and constipation; the dose being one and half grains.

### SALIPYRIN.

ACCORDING to Gultmann<sup>3</sup> salipyrin is a combination of salicylic acid with antipyrin. It is prepared by adding salicylate of soda to a weak, hot solution of antipyrin. On cooling, the solution yields crystals of salipyrin, which is a white powder with a slightly sweet taste, and odorless; it is but feebly soluble in water, but freely so in alcohol. The author has used the drug for a great number of patients, and finds the dose to be from one drachm to one and a half drachms, in twenty-hours. It should be given in divided doses, thirty grains being first given, followed by doses of fifteen grains. There is generally obtained in this manner a fall in temperature of  $1\frac{1}{2}^{\circ}$  C. to  $2\frac{1}{2}^{\circ}$  C. The maximum effect is observed after three or four hours, and is accompanied by more or less profuse sweating, but never with rigors. No ill effects have been observed to follow the use of the drug, and only in one case was a slight erythema produced. When used in rheumatism, a decided analgesic effect was produced, as well as a fall in temperature. The author finds that, like antipyrin, the action is more manifest in intermittent than in continued fevers.

### SIR JOSEPH LISTER ON THE SPRAY.

IN his address before the Berlin International Medical Congress on the Present Position of Antiseptic Surgery, Sir Joseph Lister in referring to the use of the carbolic spray, made a very candid and handsome avowal, setting an example which it would be well if scientific investigators could always bring themselves to follow when dealing with their own past errors. It is comparable to Lyell's conversion to Darwin, after he was sixty years old. Sir Joseph said:

"As regards the spray, I feel ashamed that I should have ever recommended it for the purpose of destroying the microbes of the air. If we watch the formation of the spray and observe how its narrow initial cone expands as it advances, with fresh portions of air continually drawn into its vortex, we see that many of the microbes in it, having only just come under its influence, cannot possibly have been deprived of their vitality. Yet there was a time when I assumed that such was the case; and, trusting the spray implicitly as an atmosphere free from living organisms, omitted various precautions which I had before supposed to be essential. Thus in opening the pleura in empyema for the purpose of evacuating the pus, and introducing a drainage-tube, and afterwards in changing the dressings, I had previously applied over the opening a piece of cloth steeped in an antiseptic lotion to act as a valve and prevent the entrance of air during inspiration. But under the spray I omitted the valve and allowed the air to pass freely in and out of the pleural cavity, although I used the spray at such a distance from the producing apparatus that it was dry and transparent with the particles of carbolic solution widely separated from each other. And these particles cannot have been in more than instantaneous contact with much of the dust before it was drawn within the chest and securely protected by the pus or serum from any further action of the antiseptic. It is physically impossible that the microbes in such dust can have been in any way whatever affected by their momentary presence in the spray.

"Yet we did not find our results in the treatment of empyema rendered worse by this false confidence in the spray. . . . If then no harm resulted from the admission day after day of abundant atmospheric organisms to mingle unaltered with the serum in the pleural cavity, it seems to follow logically that the floating particles in the air may be disregarded in our surgical work. And if so, we may dispense with antiseptic washing and irrigation; provided always that we can trust ourselves and our assistant to avoid the introduction into the wound of septic defilement from other than atmospheric sources."

### COMBINATION OF OPERATIVE TREATMENT WITH KOCH'S REMEDY IN PHTHISIS.

PROFESSOR SONNENBURG<sup>1</sup> has published a preliminary report on the results of the combination of operative interference with injections of Koch's fluid in four cases of pulmonary phthisis. The operations were performed in the presence of Koch himself between December 12th and 17th. The object was to test the practicability of treating cavities of the lungs by mak-

<sup>1</sup> *Deutsche Medizin. Wochenschr.*, January 1st, and *British Medical Journal*, January 17th.

ing an opening from the outside through which necrosed tissues might be eliminated, and then applying Koch's method in the usual way. In three of the cases there was a cavity in one apex, the anterior wall of the cavity was firmly adherent over a large surface to the costal pleura, so that the cavity could be opened without any risk of pneumothorax.

The following is the mode of procedure adopted: Chloroform having been administered, an incision is made beginning at the sternum and extending outwards from ten to twelve centimetres, in a direction parallel to, but from one and one-half to two centimetres below, the clavicle. The pectoralis major is next divided, and the soft parts being held aside with retractors, the lower edge of the first rib is laid bare. The periosteum is then detached from the anterior and posterior surfaces of the first ribs with blunt instruments. A broad retractor is then passed between the posterior layer of periosteum and the pleura so as to protect the latter from injury, and an arched segment is cut out of the lower border of the rib with cutting forceps. By this means the intercostal space is enlarged, and the pleura is next exposed by careful separation of the muscular fibres. An exploratory puncture is then made into the lung with a small syringe, which usually enters the cavity, as is shown by the escape of a certain amount of pus. The opening made by the syringe is next carefully enlarged with a fine pointed thermocautery, red hot, which is pushed slowly along the track of the exploring needle into the vomica. When the cavity is reached a little thick muco-pus generally wells up in the bottom of the wound. The opening having been somewhat enlarged with the thermocautery, both the cavity and the wound are stuffed with sterilized cotton.

The three patients with cavities at the apex bore the operation well, and the subcutaneous injections of Koch's fluid were soon afterwards proceeded with. It is too early to judge of the results, but, so far, they do not appear to be very striking. In the fourth case, the lung was not adherent to the pleura, and the opening into the cavity was followed by the development of pneumothorax. The patient, however, recovered from this, and the lung is now fixed to the chest wall by pleuritic adhesions.

### PRESCRIPTIONS.

**HYPNAL.**—Hypnal is not very soluble in cold water, but becomes more so on the addition of a little alcohol, or it may be given in capsules. An excellent formula, as given by Fränkel<sup>1</sup> is as follows:

R Hypnal . . . . . gr. xv.  
 Extract. cannabidis induræ . . . . . ʒ j.  
 Aquæ . . . . . S iv. M.

Half of this may be given at a dose, and repeated if necessary, or the entire amount may be taken at once.

**SALICYLIC ACID FOR CORNS.**—Whelpley<sup>2</sup> recommends the following:

R Acid salicylic . . . . . 9 parts.  
 Extract. cannabidis induræ . . . . . 1 part.  
 Colloidi . . . . . 48 parts. M.

Apply to the corn every night with a camel's-hair brush, and allow it to dry on. The foot must be clean and dry before it is applied.

### METEOROLOGICAL RECORD,

For the week ending Jan. 24, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Brookline . . .	12,676	4	1	50.00	—	25.00	25.00	—

Deaths reported 2,733; under five years of age 1,025; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 379, acute lung diseases 535, consumption 337, diphtheria and croup 135, typhoid fever 53, measles 51, scarlet fever 47, diarrhoeal diseases 37, whooping-cough 26, cerebro-spinal meningitis 14, erysipelas 12, malarial fever 6.

From scarlet fever New York 20, Brooklyn 9, Philadelphia 7, Chicago 5, St. Louis 3, Boston, Cambridge and Newton 1 each. From diarrhoeal diseases New York 11, St. Louis 7, Chicago 6, Philadelphia 1, Boston and Lowell 3 each, Nashville 2, Brooklyn and Washington 1 each. From whooping-cough New York 17, Chicago 4, Brooklyn and Washington 2 each, Lowell 1. From cerebro-spinal meningitis Chicago 6, Brooklyn 1, Boston 3. From erysipelas St. Louis and Washington 3 each, New York and Chicago 2 each, Boston and Salem 1 each.

<sup>1</sup> Bull. Gen. de Therap.; September 20th.

<sup>2</sup> Notes on New Remedies.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 24, 1891, TO JANUARY 30, 1891.

By direction of the Secretary of War, Major WILLIAM H. GARDNER, surgeon, is relieved from further duty in the field, and will return to his proper station. S. O. 19, Par. 2, A. G. O., Washington, D. C., January 23, 1891.

By direction of the Secretary of War, the extension of leave of absence, on account of sickness, granted Major STEVENS G. COWDREY, surgeon, in Special Orders No. 302, December 27, 1890, from this office, is still further extended two months, on surgeon's certificate of disability. S. O. 19, Par. 3, A. G. O., Washington, D. C., January 23, 1891.

By direction of the Secretary of War, Captain WALTER REED, assistant surgeon, is relieved from temporary duty at Fort Kough, Montana, to take effect as soon as his services can be spared by the commanding officer of that post, and will then return to Baltimore, Md., and resume his duties in that city as attending surgeon and examiner of recruits. S. O. 20, Par. 3, A. G. O., Washington, D. C., January 24, 1891.

By direction of the Secretary of War, Captain WILLIAM O. OWEN, JR., assistant surgeon, is relieved from temporary duty with troops in the field, to take effect as soon as his services can be spared, and will then return to Muskogee, Indian Territory, and resume his leave of absence. S. O. 20, Par. 3, A. G. O., Washington, D. C., January 24, 1891.

By direction of the Secretary of War, Captain CHARLES M. GANDY, assistant surgeon, is relieved from temporary duty in the field, to take effect when his services can be spared by the commanding officer of the troops with which he is serving, and will then return to Ocean View, Cape May County, N. J., and resume his leave of absence. S. O. 21, Par. 1, A. G. O., Washington, D. C., January 26, 1891.

By direction of the Secretary of War, Captain ROBERT J. GIBSON, assistant surgeon, is relieved from further temporary duty in the field, to take effect as soon as his services can be spared by the officer commanding the troops with which he is serving, and will then return to New Haven, Conn., and resume his leave of absence. S. O. 22, Par. 6, A. G. O., Washington, D. C., January 27, 1891.

By direction of the Secretary of War, Captain WILLIAM STEPHENSON, assistant surgeon, without delay, from Columbus Barracks, O., to Fort Wayne, Mich., and report in person to the commanding officer of that post for temporary duty, and upon completion thereof will return to his proper station. S. O. 23, Par. 13, A. G. O., Washington, D. C., January 28, 1891.

# OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JANUARY 24, 1891.

R. P. CRANDALL, assistant surgeon, ordered to examination preliminary to promotion.

T. A. BERRYHILL, passed assistant surgeon, detached from "M. Arthur," and wait orders to "Marion."

W. H. JONES, surgeon, detached from "Swatara," proceed home, and granted six weeks' leave.

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE FOUR WEEKS ENDING JANUARY 24, 1891.

BALDACH, P. H., surgeon. Granted leave of absence for seven days. January 12, 1891.

PERMANO, GEORGE, surgeon. To proceed to Pittsburgh and Erie, Pa.; Cleveland and Toledo, O.; Detroit, Mich.; and Buffalo, N. Y., as inspector. December 29, 1890.

CARRINGTON, P. M., passed assistant surgeon. Granted leave of absence for seven days. January 16, 1891.

GILDEROS, H. P., assistant surgeon. To report in person to the supervising surgeon general, January 16, 1891. Detailed for special duty, port of Georgetown, D. C. January 13, 1891.

STEPHENSON, W. G., assistant surgeon. To proceed to New Orleans, La., for temporary duty. January 6, 1891.

# SECTION ON STATE MEDICINE OF THE AMERICAN MEDICAL ASSOCIATION.

Dr. Benjamin Lee, Secretary of the State Board of Health of Pennsylvania, has been appointed Secretary of the Section on State Medicine of the American Medical Association. As the meeting takes place in Washington, May 5th, it is important that all papers intended for this Section should be in his hands by the 5th of April. All members of the Association desiring to be named in the Section, are requested to forward him their names at 1532 Pine Street, Philadelphia.

# LEGISLATIVE HEARING ON THE SPREAD OF CONTAGIOUS DISEASE.

COMMONWEALTH OF MASSACHUSETTS.  
STATE HOUSE, BOSTON, January 30, 1891.

The Committee on Public Health will give a hearing to parties interested in the petition of C. Irving Fisher and others for legislation to protect the community from the spread of malignant contagious diseases, at room No. 16, State House, on Monday, February 5th, at 10.30 o'clock A. M.

GORHAM D. GILMAN, *Chairman*.  
WILLIAM D. HODGES, *Clerk of the Committee*.

# SOCIETY NOTICES.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION. — This Association was organized on January 22, 1891, at the Academy of Medicine, No. 17 West 43d Street, New York, by the adoption of a constitution and by-laws, and the election of the following officers: President, G. Betton Massey, M.D., Philadelphia; Vice-presidents, William James Morton, M.D., and Augustin H. Goebel, M.D., New York; Secretary, William H. Walling, M.D., Philadelphia; Treasurer, Geo. H. Role, M.D., Baltimore. Executive Council, Horatio R. Bigelow, M.D., Philadelphia; Franklin H. Martin, M.D., Chicago; Wm. F. Hutchinson, M.D., Providence, R. I.; Frederick Peterson, M.D., New York; and Channancy D. Palmer, M.D., Cincinnati, O.

The object of the Association, as stated in the second article of the constitution, is "the cultivation and promotion of knowledge in whatever relates to the application of electricity in medicine and surgery."

The Association starts with a strong and vigorous membership, and has every prospect of a most useful and successful career.

The next meeting will be held in Philadelphia, in September, of this year. Wm. H. WALLING, M.D., *Secretary*,  
2005 Arch St., Philadelphia, Pa.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT. — A regular meeting of the Society will be held on Monday, February 9, 1891, at the Medical Library, 19 Boylston Place, at 8 o'clock P. M.

Readers: Dr. W. N. Bullard and Dr. E. H. Bradford, "A Case of Cerebral Tumor." G. G. SEARS, M.D., *Secretary*.

# DEATHS.

W. J. McClure, M.D., of York, Pa., died, January 24th, aged fifty-two.

E. L. Corbin, M.D., died in Washington, D. C., January 16th. He had retired from practice for some years, owing to ill health. During the war he made an excellent record as surgeon of the One Hundred and Fifty-second New York Regiment.

J. Dickinson Miller, M.D., Medical Director, U. S. N., retired, died, January 24th, at Mount Airy, Pa., aged about eighty years. He joined the navy as assistant surgeon in 1836, served in various squadrons, and was put on the retired list in 1872.

Henry M. Martin, M.D., Surgeon, U. S. N., died in Philadelphia, January 16th.

Henry Salvin Gill, M.D., died in New York, January 16th, aged thirty-eight.

Thomas Graham Balfour, M.D., F.R.C.P., F.R.S., Surgeon-general, retired, Honorary Physician to the Queen, etc., died, January 17th, aged seventy-seven.

Giambattista Borelli, M.D., Senator of the Kingdom of Italy, died, January 10th, aged seventy-eight.

J. G. F. Baillarger, M.D., formerly President of the Paris Academy of Medicine, died, December 31, 1890, aged eighty-two.

William Strange, M.D., F.R.C.P., Vice-president of the British Medical Association, died, January 5th, aged seventy-five.

A CASE OF SUCCESSFUL TREPHINING FOR SUBDURAL HÆMORRHAGE PRODUCED BY CONTRE-COUP.<sup>1</sup>BY JOHN HOMANS, M.D.,  
*Visiting Surgeon Massachusetts General Hospital,*AND G. L. WALTON, M.D.,  
*Physician to the Neurological Department Massachusetts General Hospital.*

J. M., a waiter, born in England, twenty-eight years of age, married, was admitted to the Massachusetts General Hospital, May 13, 1890, in the service of Dr. Homans.

He was brought in unconscious, and was said to have been thrown from a horse just outside the hospital, and was supposed to have struck his head upon the cobblestones. His temperature was 98.2°, and his pulse was 60. There was a hematoma, with abrasion of the scalp, at a point corresponding to about the middle of the suture between the right parietal and occipital bones. The right pupil was dilated when the patient was brought in. When seen by Dr. George Eliot, within two minutes after entrance, consciousness was returning, the pupils were equal, and reacted normally. There was no bleeding from the nose or ears; the pulse was slow and full. The hematoma was laid open under cocaine anesthesia, and the finger was introduced. No fracture was made out, although through the swelling there appeared to be a depressed fracture. One stitch was taken. Apparently perfect consciousness returned. There was no paralysis.

May 15th (third day). The patient was quiet, sleeping most of the time until evening, when he became delirious, and got out of bed several times. He was easily quieted. The temperature was 102°. The bowels were moved by calomel.

May 16th (fourth day). The patient is almost comatose. Aphasia has appeared.

May 21st (ninth day). The temperature has gradually come down to normal. The pulse is a little faster, though still slow and full. The general condition has remained about the same as at the last entry. Nourishment is well taken. The patient is not violent, but leaves his room from time to time. He answers "Yes" to almost every question. When asked if he wants anything says, "I want"—but cannot find the word. He apparently understands what is said to him, and is, perhaps, a little brighter this morning. Early in the morning the night nurse chanced to see spasmodic twitching of the muscles of the right side of the face, and especially noticed that the right corner of the mouth was drawn down. The pupils were unaffected. The spasm was limited to this locality, and the convulsion lasted perhaps one minute. Slight twitching of the muscles of the chin on the right side recurred during the day at intervals of several hours. At 10 p. m. convulsive movements appeared in the muscles of the left side of the face. These spasms were similar to those already noted, excepting that the right eyelid was closed, while the left side of the face was twitching. He seemed conscious, though unable to talk. Dr. J. W. Elliot, who was temporarily acting for Dr. Homans, had the patient removed from the general ward, apprehending further cerebral developments.

May 22d (tenth day). At 3.30 A. M., the right side of the face was convulsed as at first. Slight twitchings and similar convulsive movements ensued at intervals of two and three hours during the day, increasing in frequency towards night. The facial muscles and the platysma myoides alone were affected.

May 23d (eleventh day). The convulsions recurred at intervals of ten to fifteen minutes. Dr. Walton was asked to see the case at 10 A. M. At this time convulsions were recurring every fifteen minutes, commencing at the right angle of the mouth and spreading to all the muscles of the face, involving very slightly the occipito-frontalis, and in a marked degree the platysma. The convulsions lasted about one minute, the face remaining drawn to the right for a short time. There was paresis of the right side of the face between the convulsions; no paralysis elsewhere. The patient was unable to protrude the tongue, which appeared to deviate to the right. Some of the convulsions ended suddenly, others gradually; in the latter the angle of the mouth remained convulsed until the last. The patient was apparently conscious of his surroundings to a certain degree, and on being questioned, made attempts to reply. The attempts were ineffectual, partly, apparently, on account of aphasia, and partly on account of lingual paralysis. The pupils were alike, and reacted normally. There was no rolling of the head or eyes. As a result of this consultation with Dr. Walton, immediate operation was decided upon, the convulsions locating the trouble (probably hæmorrhage) at the lower end of the fissure of Rolando, on the left, the side opposite the injury. At 3.30 P. M. the convulsions recurred every three or four minutes, each lasting about two minutes. At this time the convulsion, which began as before, at the right angle of the mouth and in the platysma, spread rapidly to all the muscles of the face, and in several instances to the right arm and leg, then to the other side of the body, and became general. The spasms were generally clonic in character, but in one convulsion the entire body was in a state of tonic rigidity. In the convulsions limited to the face, consciousness was not lost and natural movements were made with both arms, the patient at times crying out and sobbing, with copious tears and salivation, but not frothing at the mouth. The tongue shared in the convulsions, being drawn to the right with clonic spasms, striking against the teeth violently, accompanied by a clucking noise. At 4 P. M., the head and eyes rolled to the right for the first time. The head was shaved and prepared for operation, the fissure of Rolando being carefully marked out with an aniline pencil; the scalp being scrubbed and poulticed with corrosive sublimate, 1 to 2,000. He was now seen by Dr. Putnam, who concurred in the desirability of an operation, as had also Dr. Carter, who saw him earlier. By this time the entire body was in a state of almost continuous tonic rigidity.

## OPERATION (BY DR. HOMANS).

The patient having been etherized, a large semi-circular incision was made about three inches in diameter with the convexity upwards, the fissure of Rolando running across it at right angles to the line between its two extremities. The incision was made down to the bone, the periosteum elevated and the flap retracted. The point of selection was just anterior to the lower end of the fissure of Rolando, where a

<sup>1</sup> Read before the Surgical Section of the Suffolk District Medical Society, December 3, 1890.

large button was removed by a trephine one and one-half inches in diameter. Nothing abnormal was found about the bone. The dura mater was bulging and tense, somewhat yellowish and opaque, non-pulsating and very prominent. Incision through it revealed a dark clot. The opening was enlarged, and the clot partially removed. It was found to extend in every direction under the dura mater. The brain itself was prominent and bulging where the dura mater had been opened, but on removal of the clot the prominence subsided, and pulsation gradually appeared. The trephine opening was enlarged anteriorly and posteriorly with rongeur forceps, and the entire clot turned out. The pia mater was cloudy and discolored, and in one spot (about the size of a five-cent piece) black. This point was apparently just behind the fissure of Rolando in the region of the platysma centre (Fig. 1). Incision through the pia mater at this point revealed a small clot, which was turned out.

FIG. 1. The lighter shading represents approximately the seat of the larger (subdural) hemorrhage; the dark round spot, the underlying (subpial) hemorrhage revealed on turning out the former.

When the trephine opening was enlarged downwards and backwards, a larger amount of clot was removed together with bits of brain substance, in the more dependent part. The brain was lacerated to a considerable extent. The clot was soft, non-friable and black. No bleeding point was found. The blood and clot were washed out with warm water. A quill drainage-tube was introduced where the brain was lacerated, and was brought out at the edge of the wound just above and behind the insertion of the auricle. Another quill was placed across the upper segment of the wound, and the flap was replaced and sutured with continuous catgut. A few branches of the temporal artery were tied. Dry dressing was applied and a skull cap. The operation lasted an hour and twenty minutes. The condition after operation was excellent, and after recovery from the ether, the patient was apparently conscious, though unable to speak. There were no convulsions.

#### SUBSEQUENT HISTORY (BY DR. WALTON).

May 24th (day following operation). There have been three slight convulsions during the night, confined to the corner of the mouth. He is apparently conscious, and appears to understand simple sentences at times, although occasionally misinterpreting. For example: when asked to raise his hand, he raises his head; and when asked to put out his tongue, he raises his hand. (Sensory aphasia, word deafness.) H. hearing is apparently perfect. Motor aphasia is marked, almost preventing utterance. For example: "Have you headache?" Answer: "I I it is." During the following night there was a slight convulsion of the right corner of the mouth.

May 26th. Improving. At times he raises his hand,

and makes other motions correctly when asked; at other times he misinterprets the request. He is unable apparently to protrude the tongue. Careful examination being made for loss of sensation, including that of the face, gives a negative result. The patient is brighter; makes unsuccessful attempts at conversation, and makes his wants known regarding the bedpan, etc., by gestures.

May 27th. He generally understands what he is asked to do, although attempts at conversation are still ineffectual. When asked what he complains of, he answers, "I have a—what do you call it?—What is it?—Why a?" (points to head).

May 29th. He puts out his tongue for the first time, and does it readily. There is marked deviation to the left. When asked how he felt, he said, "What is the matter with me now is a little—little"—"Headache?"—"Yes, headache."

May 31st. The tongue is protruded fairly straight. The examination for facial paralysis is unsatisfactory. When asked to shut his eyes, he winks. When asked to shut his eyes and hold them shut, he shuts his mouth tightly; on the request being repeated, he nods his head. When asked to open his eyes wide, opens his mouth wide; on the request being repeated, he protrudes his tongue. Being asked if he felt a touch on the right cheek, he did not understand the question, but kept saying that the other side was sore. His motions, however, showed that there was no loss of sensation. Attempts at conversation resulted in many inarticulate noises and repetitions of the word *yes*, interspersed with occasional correct sentences.

June 6th. Motor as well as sensory aphasia improving, and the patient is becoming quite talkative. For example: "How is your head?"—"Yes, it is a kind of a—little something gone—a kind of a gait—yes."—"Let me hear you say headache."—"Gearish, isn't it? G-e-r-n, isn't it?—G-l-e-a-u, isn't it?" When asked to put out his tongue, he spells "W-e-a-l-t-h," but shuts and opens his eyes when asked, and raises each hand correctly. When shown a fan and asked, "What is that?" answers, "That is a—what do you call it? a geremea."—"Is it a fan?"—"Yes, I was trying to say a fan—I believe I have raised that seventy-four—I believe I have got it right."—"Can you laugh?"—"Pretty good now," (opening his mouth).

Examination now reveals a paresis of the muscles supplied by the lower branches of the right facial nerve. The lightest touch is localized accurately by him on the right side of the face, however, as on the left with the eyes shut. Also on the right hand and other parts of the body. The grasp of the right hand is somewhat weaker than the left, although both are good. He states, "I think my right hand is bigger." "Do you mean weaker?" Answers, "Yes." Combined and separate movements of the hand, arm and wrist are apparently normal. He is unable to read when given a book, although his sight is perfect, and he was able to read before the accident. He recognized ordinary objects and their uses, showing that there was no "mind blindness" excepting for words. (Word blindness.) When asked to write his name he spelled, "M-o-r-d" to himself, and then wrote, forming the letters perfectly.

*Lordard*

Attempting to read what he had written, he read, "F-o-r-d." When asked if that was his name said, "M-a-r-g-h—ain't it?" When asked to write *for*, wrote,

*Bustnancee*

then read what he had written, "F-a-s-m-a-w-e." When asked again what he had written, said, "It is supposed to be w-duft-nenft-m-a-st-mance." When asked if he felt a touch, he made various irrelevant answers, but appreciated perfectly the fact that he was expected when touched to put his finger on the same spot with his eyes closed, which he did perfectly and without hesitation.

June 10th. Examined in the presence of the Massachusetts Medical Society. Being asked to write his name wrote "Calais," and when asked to read it, read "V-a-v-a-v-a." When requested to open his eyes, etc., at first he responded incorrectly, afterwards correctly. His intelligence at this time seemed excellent.

June 21st (a month after operation). Talks freely and volubly on all subjects, only occasionally misplacing a word. He gives a complete account of a former attack of indigestion, only using the word "accused" instead of "relieved." ("That medicine *accused* me greatly.") He says, "I am sorry to see you," then corrects himself and says, "I am glad to see you." Again: "I am glad Dr. Elliot has a sore hand. I mean I am sorry," etc.

July 14th. Writes nearly, and reads quite, correctly, reading a long sentence from the Dispensatory, only stumbling at the word "Pharmacopœia" which he reads correctly the second time. In conversation he only forgets an occasional word. The shape and seat of the skull opening, as made out by feeling the edges through the scalp, is shown in Fig. 2.

FIG. 2. The irregular line represents the opening in the skull left by the rongeur forceps, the dotted line showing the trephine opening. The line of the fissure of Rolando is shown.

After having been discharged, with orders to report occasionally, the patient presented himself July 16th, and was admitted to the service of Dr. Cabot, from whose records the following notes are taken. There was a large swelling above the left ear, extend-

ing over the temple. There was a small opening discharging a little pus. There was no tenderness and no pain, except a slight frontal headache, principally on the left. The patient was weak and somewhat rambling in his talk. The temperature was 101.5°, the pulse 84. A phenyle poultice was applied over the swollen area. A letter written to the *Globe* at this time (but not forwarded) is appended.

MASSACHUSETTS GENERAL HOSPITAL, July 17, 1890.

EDITOR GLOBE NEWSPAPER: Sir in hearing from several people that they read of my accident in front of the Massachusetts Hospital from the *Globe* I believe in writing to the *Globe* for thanks for allowing friends to hear quickly what hurt I got but more so, for the Hospital and the Doctors, that wonderfully saved my life, from what I heard while I was getting wonderfully well, I heard the whole affair of me, and having heard in time, some various things that have been done by accident, and some wonderfully actions by Doctors I knew that the affect I got from the horse was wonderful by the Doctors to keep me from dying I know that when the brain has to be taken and cleaned and the patient quickly gets good and strong and get home is a very wonderfully affect of the doctor and to show that Doctors will try to do all their labor to give the people can be seen every day. Therefore if we the people that get afflicted ought to thanks that we are not in the Interior of Africa but in a civil city where occasionally we come across Men who will do all their best to affect us.

J. M.

July 17th. The swelling has lessened. There is still some headache. There is a slight free discharge. (Urine: color normal, reaction acid, specific gravity 1016, no albumen, sed. urates.)

July 18th. There is scarcely any headache, the discharge is lessened, the swelling is slight. An ice-bag was applied to the head all day.

July 19th. The patient is doing well. Dry dressing applied.

July 21st. Some pain is complained of, localized over the frontal region on both sides. Phenyle poultice and ice-bag to the head.

July 24th. Patient is doing well, occasionally complaining of pain in the head.

July 27th. There is little pain, scarcely any discharge, no swelling or tenderness.

July 28th. There is no pain. The patient feels very well.

July 30th. Last night the patient began to vomit at eleven o'clock. He complained of pain in the mid-frontal region, extending back to the vertex. He slept very little during the night. This morning he has vomited once. The temperature is 101°. The pain has lessened somewhat. He has been rather drowsy nearly all day. The temperature in the afternoon rose to 102°, the pain still continuing, unrelieved by ice-bag or phenacetine.

July 31st. Patient feels better. He slept fairly last night. The pain has lessened. The ice-bag is still applied. The bowels were moved copiously by ten grains of calomel. He feels rather weak. The pulse is fair, the temperature lower. There is no swelling or tenderness on the left side of the head. The discharge is very slight. Urine: color normal, reaction acid, specific gravity 1026, sediment slight.

August 1st. There is considerable pain in the head, somewhat relieved by the ice-bag.

August 2d. The pain in the head is less. He complains of a "silly" feeling. Feels rather weak, and is unable to sit up long.

August 3d. There is scarcely any pain in the head. He feels much better, and has sat up nearly all day.

August 4th. There is less pain. The patient is quite comfortable, and about the ward. Vomited last night.

August 5th. Very little pain; no discharge. Ice-bag still used.

August 6th. Is feeling very well. Eats better.

August 7th. Very slight pain in both temporal regions. General condition good.

August 8th. Patient is feeling very well. There is no discharge. Punctice omitted. Very slight pain in occipito-frontal regions.

August 9th. Scarcely any pain in vertex; slight pain in infra-orbital regions, especially in the left.

August 11th. Slight pain as in last entry.

August 15th. Very little pain since last note. General condition good. Patient discharged.

Since his last discharge from the Hospital there has been no recurrence of trouble, and after a month the patient was perfectly well and working regularly as a waiter.

As an important factor in the favorable progress of this case, the writers would here express their appreciation of the labor and untiring devotion of Dr. George Eliot, the house-officer in charge.

The test of practical experience has now been applied to nearly every form of operative measure upon the cranial contents which neurology has been able to suggest, or surgery to execute. Among the most favorable cases, both as regards accuracy of localization and success in removal, must be accounted those of cortical hemorrhage.

Important advance has been made, it is true, in the treatment of intra-cranial tumors and in other directions, through the perfection of cerebral localization and the progress of cerebral surgery. The dangers and difficulties, however, inherent in this branch of the subject, of necessity reduce successful cases to a comparative minimum. We must at once eliminate deep-seated, multiple, and infiltrating tumors, as well as those of considerable size; those capable of absorption by internal remedies (gummata), and those accompanied by similar disease in other parts of the body (certain sarcomata, carcinomata, and tubercular growths), leaving a residue for which ten per cent. (the estimate of operable cases made by W. Hale White<sup>2</sup> on an analysis of one hundred cases of cerebral tumor verified by autopsy) is probably a liberal allowance. Deducting from this percentage those of mal-success due to the operation itself, and those in which the symptoms are not sufficiently marked for accurate diagnosis at a period when operation would be of avail, and the number remaining, offer a field which, though brilliant, and well worthy of the widespread enthusiasm the subject has aroused, is not so extended a one as might be wished.<sup>3</sup>

Whatever grounds cause the neurologist to hesitate, and the surgeon to stay his hand where new growth is under consideration, the question of surgical interference for removal of superficial hemorrhage is far simpler, and the demand, as a rule, more urgent. Familiarity with the symptoms of this lesion is there-

fore of prime importance, as well as that with the indications for operation.

Regarding the latter Nancrede<sup>4</sup> says: "When hemiplegia occurs after a blow upon the head, or hemiplegia with hemi-spasm, however slight be the injury—provided that it is in the temporo-parietal region, even although it be not directly over the motor area—the surgeon is justified in exploring that area.

"In the coma resulting from intra-cranial hemorrhage—from the middle meningeal artery for instance, as already pointed out—cerebral localization should guide the surgeon's hand, unless in those instances when the effusion is so large as to present no limited compression symptoms. . . .

"In those cases where the paralysis is on the side of the injury, that is, the result of hemorrhage or fracture by counter-stroke, provided that laceration of the brain seems improbable, an operation over the motor-area of the side opposite to that of injury would seem indicated. This must be a rare condition, and is too often complicated with cerebral laceration at or near the site of the external injury itself."

It is with one of these comparatively rare<sup>5</sup> cases that we have to do in this report, which amply illustrates both in the paralyzes, the spasms, and in the subsequent symptoms, the importance of cerebral localization, and the confidence with which we may rely upon its teachings. The case also shows the tolerance of laceration on the part of the brain, even in a part important to its functions, and thus tends to do away with the contra-indication above enunciated. Whether laceration was present under the point of external injury also we have no means of ascertaining; there could hardly fail to have been a certain degree. No symptoms, however, arose or have arisen pointing in that direction, unless possibly the slight convulsion on the left side, while the recovery has been perfect, notwithstanding a very considerable laceration at the dependent part of the seat of hemorrhage, that is, as nearly as could be made out, of the first temporal lobe and the supra-marginal convolution.

With regard to the diagnosis of hemorrhage at the surface of the brain, the symptoms, in case of extensive lesion, are similar, whether the rupture be of the middle meningeal artery (producing hemorrhage between the dura mater and bone), or of the underlying vessels of the pia mater (producing hemorrhage into the arachnoid cavity). It will, therefore, not be out of place to enumerate the symptoms of hemorrhage from the middle meningeal artery in the order considered, to be that of their comparative value by Jacobson, in his exhaustive treatise on this subject in the Guy's Hospital Reports.<sup>6</sup>

(1) A period of consciousness intervening between the accident and the symptoms of compression. This period may vary, according to Wiesman,<sup>7</sup> from fifteen minutes to eleven days. It may be absent, as Jacobson states, on account of (a) the severity of the original violence, (b) depression of bone, (c) accompanying injury to the brain, (d) the extravasation having been

<sup>1</sup> International Encyclopedia of Surgery. Ashhurst. Vol. v, p. 91.

<sup>2</sup> These cases are not so rare but that certain typical ones have been reported, for example, a case by Gross (System of Surgery), verified by post-mortem; also a case by Watson, with recovery due to operation. (Lancet, 1866, 11, p. 215.) In a third case the operation was performed on the side of the injury and the patient lost, the hemorrhage being on the opposite side.

<sup>3</sup> Guy's Hospital Reports, 3d series, 1885, 6, p. 256.

<sup>4</sup> Deutsch, Zeitsch. f. Chir., Bk. 3, Heft 1 and 3; Annals of Surgery, December, 1885, p. 502.

<sup>5</sup> The same views are held by other Clinicians. Practitioner, May 1, 1889, the description of "St. Germain's case of cerebral tumor," which would have warranted surgical interference, and in only 16 of which an operation might have been successfully performed.

immediate and copious owing to the size of the branch where ruptured, and (e) drunkenness.

(2) Hemiplegia, paraplegia, rigidity. The hemiplegia is not always present or always complete; where partial, the arm is likely to be affected without the leg, or with only a paresis of the leg, but the leg is probably never paralyzed without the arm. Paraplegia may occur in the case of extension from one hemisphere to the other. The paralysis may, in exceptional cases, be temporary.

(3) Dilatation (usually unequal) of pupils, the pupil being generally larger on the side of the hæmorrhage, on account of extension forward upon the sphenoidal fissure, causing paralysis of the third nerve. (Hutchinson.<sup>8</sup>)

(4) A slow, full, and laboring pulse.

(5) Unconsciousness, passing into coma.

(6) Stertorous, laborious or "snorting" respiration, or the breath emitted from the corner of the mouth like a whiff or puff of smoke. (Guthrie.<sup>9</sup>)

(7) Ecchymosis or contusions of the parietal and temporal regions, giving rise to a puffy or pulpy feel, and bloodlessness of the bones overlying the clot, probably due to interference with the blood supply on account of separation of the dura mater. (Abernethy.)

Wiesman<sup>10</sup> adds, vomiting, unilateral impairment of sensation, aphasia, disorders of the bladder and rectum, automatic movements and lying always on one side, and rise in temperature. He adds also that convulsions may precede the affection.

The diagnosis between hæmorrhage above and that below the dura mater is so difficult, that little time need be spent in the effort, especially since the treatment is the same, and operation is called for with equal urgency in both. Jacobson has alluded to the following points in diagnosing laceration of the brain, though stating that there are none of certain reliability. (1) In middle meningeal hæmorrhage any scalp wound or bruise is usually over the area of the artery. (2) The interval of lucidity is likely to be absent or little marked in laceration of the brain. (3) Convulsive twitchings militate against middle meningeal hæmorrhage, and point more often to laceration of the brain.

In the case here reported, there was no hemiplegia, but the localized convulsions of true Jacksonian type, commencing without unconsciousness at the corner of the mouth then gradually extending to the extremities and becoming general, pointed so accurately to localized cortical irritation, as to furnish a much more urgent symptom than even hemiplegia. It seems probable that the small subpial clot underlying the larger one, furnished the irritation for the convulsions, especially since its seat, as nearly as could be determined, was over the platysma centre. The laceration of the brain may have contributed to this symptom, although it was rather far from the motor region implicated. The general symptoms of compression were, however, due to the larger hæmorrhage. The most interesting symptom as regards localization, was the aphasia, which was studied carefully during convalescence, and is reported in detail. The motor aphasia was typical and of the ordinary form. The sensory aphasia (word deafness) was extremely persistent, due probably to destruction of brain tissue in the posterior

portion of first temporal lobe. Word blindness appeared to be also present, a symptom which would point to extension backwards towards the angular gyrus. These defects would probably explain the difficulty in writing, without assuming lesion of the centre for writing.<sup>11</sup>

The turning of the head and eyes to the opposite side, which appeared shortly before the operation, pointed to extension forwards and upwards towards the centre assigned to this movement by Ferrier, at the posterior end of the second frontal convolution. Certain, though not yet abundant, cases seem to show that this centre corresponds in man to that in monkeys, for example, a case, reported by one of the writers,<sup>12</sup> of sub-cortical glioma passing (as shown by autopsy), through the motor area and extending forward to a point at the posterior end of the second frontal convolution. The principal symptoms were convulsive movements of the face without unconsciousness, accompanied by paresis, and ushered in by marked rotation of the head and eyes to the side opposite the lesion. The same symptom was marked as regards the head, in the case of a tumor successfully removed by Bremer and Carson<sup>13</sup> which invaded the base of the second frontal convolution.

#### NOTES ON SKIN-GRAFTING, WITH REPORT OF A CASE OPERATED BY THIERSCH'S METHOD.<sup>1</sup>

BY PAUL THORNDIKE, M.D.

IN December, 1869, Reverdin presented to the Society of Surgery, at Geneva, his first article on skin-grafting, and at about the same time Mr. Pollock, at St. George's Hospital, called the attention of English surgeons to the subject. Since that time the operation in its various forms has slowly asserted its claims and now stands as a surgical procedure, the practicability and value of which are beyond question.

The original operation of Reverdin, which consists in grafting many small bits of epidermis upon granulating surfaces, previously brought into as favorable condition as possible by suitable treatment, is still used and is of unquestioned value. But its success is by no means constant, and the time required for the completion of a cure is so long, that the vast majority of cases cannot be successfully terminated. In the treatment of large ulcers the graftings must be frequent, the material for grafts abundant and easily available, and many months must elapse before a cure can be reached.

Then, too, the very best result obtainable by this method is not good enough in many cases. That is to say, we get a cicatrix as our best result, and no matter how good an one it may be, it does not in any sense compensate for the loss of true skin. The deformity resulting from the contraction of such cicatrices is of course especially to be deplored if the grafted surface happens to be near an eye or over a joint.

Recognizing this limitation of Reverdin's operation Wolfe, in 1875, described an operation for the relief of deformities due to scars about the eyelids. He

transplanted a piece of skin taken from the forearm into the wound left after the removal of his scar tissue, and stitched its edges to the surrounding skin.

He was not very successful at first, but soon found that by removing all the subcutaneous fat and cellular tissue from the under surface of his skin graft, he made adhesion of the graft almost a certainty. Since the suggestion of this improvement to his original operation the results have been much more uniformly good.

Of the sixteen cases of this operation which I find recorded since 1881 (the date of Wolfe's second article), fifteen were successful and the one failure, one of Professor Esmarch's cases, was due to "the unfavorable condition of the patient's skin."

The method has the great disadvantages that: (1) An ugly wound is left at the place from which the graft is taken, and that: (2) The amount of manipulation necessary to prepare the under surface of the graft, must injure its vitality to a greater or less extent.

In 1881 Hamilton published a most admirably prepared article on sponge grafting and reported five cases which he had treated successfully in this way. His method consists in taking bits of sponge, dissolving out the calcareous matter in them by soaking them in a dilute acid solution, and then after making them thoroughly aseptic and cutting them to fit the wound exactly, applying them under a moist dressing.

Finding that the pieces of sponge which he used were too thick and served only to retain considerable quantities of pus in their meshes, Hamilton conceived the idea of obtaining thin and delicate slices by cutting them with a microtome. In his later cases he always prepared his grafts in this way. The sponge acts as an irritant as well as a protector, and granulations spring up in its meshes, reach the level of the surrounding tissues and in time the surface heals over.

Some very remarkable cures are credited to this method, and in certain cases it is undoubtedly of value, for example, when it is desired to fill up a deep cavity with granulations in as short a time as possible. But as a method of healing over wounded or granulating surfaces it is not to be compared with the later methods of grafting.

Of the fifty-four cases which I have collected, fifty are recorded successes, but here as with the Reverdin operation, the periods of time necessary for a cure are very long, and the best end result is a cicatrix.

In 1886 a series of investigations on grafting with the skin of frogs was published in Paris, and gave a decided impetus to the study of animal grafts of all sorts. From the study of the results obtained by the use of grafts of this sort it has seemed to me that certain generalizations might fairly be made.

The advantages of using animal grafts in certain cases are:

(1) That the material for the graft is abundant and easily available.

(2) That the time necessary for a cure is rather shorter than in the case with the Reverdin operation.

(3) That the cicatrix obtained in successful cases is soft and elastic.

(4) That if it prove necessary that any length of time shall elapse between the dissection of the graft and its application to the surface to be grafted, frog-skin, which retains its vitality for an hour or more after its dissection, may be used.

The disadvantages of this method are: (1) Success

is always doubtful and a good prognosis cannot be given.

(2) The cicatrices obtained in successful cases, although soft and elastic are also very liable to break down.

In 1886, Professor Thiersch, who had for years been investigating the subject of skin grafting, and who had published several articles of histological value in this connection, presented to the Fifteenth Congress of German Surgeons at Berlin, a paper explaining his method of operating, and showed two successful cases.

Thiersch found from experience that strong antiseptic solutions were to be avoided in all skin-grafting operations as their use hindered to a greater or less extent the final union between the grafts and the grafted surface. So he began to use a salt solution for his irrigating fluid, and in his practice made this procedure an essential part of his operation.

Thiersch operates about as follows and the details of the operation may be found carefully described in an article published by Dr. Charles McBurney, in the *New York Medical Record* for October 25th, 1890. The surface to be grafted is washed clean and irrigated with the salt solution (six parts common salt to one-thousand parts boiled water). Then an incision is made around the ulcer just outside of its hardened edge, and this edge is carefully dissected away. Then the whole surface is either curetted, or the surface granulations are shaved off with a sharp knife, and all the time a light irrigation with the salt solution is kept up.<sup>2</sup> If the ulcer is on an extremity the Esmarch rubber bandage may be used, and so a bloodless operation be assured. Bleeding points are twisted, not tied, and all oozing of blood is stopped by compresses of sterilized gauze.

Absolute control of hæmorrhage is of great importance as the grafts are much less likely to adhere if put on a bleeding surface, and any small clots which may form under the grafted pieces greatly increase the liability to necrosis.

The surface thus prepared is ready for the grafts, and should be constantly irrigated with the salt solution, while the pieces to be grafted are obtained as follows:

The part from which the grafts are to be cut, preferably the front or outer side of the thigh or the upper arm, are carefully scrubbed with corrosive sublimate solution and then with the salt solution, all hair having been previously shaved off. Then with a razor flat on one side (such a one as is used for cutting sections for microscopic examination), thin pieces of skin are shaved off with a long steady stroke, the skin of the part being stretched and held tense by an assistant.

The pieces thus obtained should include but little more than the whole thickness of the epidermis and should vary in size as the occasion demands. With a very little practice pieces five inches long by one inch wide and of the required thickness can be readily shaved off, and the ease with which they are cut is astonishing when one sees it for the first time.

The grafts as they are cut, are kept moistened with

<sup>2</sup> That curetting or cutting of the granulating surface is not always essential is shown by the result obtained in a case recently operated upon by Dr. Watson at the Boston City Hospital. In this case the grafts were applied directly to the surface granulations of a large auxiliary wound, and the grafts all adhered well. It was thought best not to prepare the surface for the grafts as the wound was very large and the Esmarch bandage could not, of course, be used in this region.

the salt solution and are applied to the prepared surface, care being taken to adjust all edges and keep them from turning under. This is easily done by sliding the piece of skin off the side of the razor by the aid of a probe. The grafts should be applied in such a way that they overlap the freshened edges of the ulcer a little.

When the surface has been covered in this way, the whole is to be covered with strips of rubber tissue previously rendered aseptic and soaked in the salt solution. These strips are made to overlap like shingles on a roof, and are to be long enough to extend well beyond the edges of the ulcer. The whole is then dressed with compresses of gauze moistened in the salt solution.

The part grafted should be kept in a raised position for some minutes to lessen the liability to hæmorrhage, and the Esmarch bandage if used may be left in place for an hour for the same reason. Thiersch says, "Moisten the dressing every four hours"; but once a day is found to be often enough. In ten days to two weeks the surface is completely healed over and in one to two months the skin over it is perfectly firm and strong.

The places from which the grafts are cut bleed very slightly and if dressed in the same way as the grafted surface, heal in a week or ten days without pain.

The rubber strips should be reapplied at each dressing for about two weeks and then may be discontinued and any suitable dressing applied.

In two or three days after the operation, the grafts should be of a delicate pink color, and a yellow or brown color indicates that the graft will probably die. The appearance of a considerable quantity of pus together with rather a foul odor need not be considered as unfavorable to success. They are both almost invariably present.

Of the 123 cases which I have found, 102 (or 82.9%) were perfectly successful, that is, the grafts adhered at once, and union was perfect in about ten days. Thirteen were partially successful, some grafts doing well and others dying. And in eight (or only 6.5%) was the result so bad that a repetition of the operation was deemed necessary. Of these eight unsuccessful cases four were in syphilitic subjects; and a second operation, after a preliminary antisyphilitic treatment, was perfectly successful in each instance. In the other four cases, failure was probably due to slight inaccuracies at the time of operation.

These were not picked cases. The surfaces grafted were either fresh wounds or granulating surfaces of various sorts. There were burns, varicose ulcers, ulcers left after the sloughing away of extensively lacerated tissues, a few tubercular ulcers, and even cavities in bone left after a sequestromy. In one of Dr. McBurney's cases, the grafts attached themselves perfectly to bare bone (ramus of the jaw). Of three tubercular ulcers which were grafted, all healed nicely, a thorough curetting of the tubercular granulations being a preliminary step in each instance. These three cases were watched for five months (one of them for ten months), and in none was there any breaking down of the grafted surface.

Taking into consideration the surprisingly good results obtained with this method of operating, and the short time necessary for a cure, together with the fact that the procedure is and has been for five years just one of the well-established operations in many

European clinics (notably Schede's, Koenig's and Czerny's), it would certainly seem that it merits a careful trial in this country. This, so far as I am aware, it has not had except at Roosevelt Hospital in New York.

Judging from the experience of the past five years, it is the operation which should be done in all cases for skin-grafting on large surfaces and where an anæsthetic is permitted.

The case which I have to show to-night is one which was operated upon by Dr. F. S. Watson, who has very kindly allowed me to bring the patient here. The man, A. B., age twenty-five, was badly burned when he was three years old, and after many months of treatment was left with a large cicatrix extending over the left buttock, outer side of left thigh and calf of leg.

September 24, 1890. Entered Boston City Hospital, with an ulcer, four by four inches, on outer surface of left thigh, and entirely within the limits of the old cicatrix. The ulcerated surface was discharging profusely, and the patient was in poor condition.

October 1st. Surface was grafted with a large piece of skin taken from breast of chicken. Wolfe's method.

October 8th. Graft beginning to slough at edge.

October 16th. Whole graft sloughed away.

October 23d. Surface again covered with clean granulations, but showing no disposition to heal.

November 3d. Grafted by Thiersch's method. Ulcerated surface was then well below level of surrounding tissues, and edges were hard. The usual operation was done, the surface granulations curetted away, and the grafts applied directly to the clean surface of the fascia lata. Esmarch bandage used, and tourniquet left in place half an hour after operation.

November 4th. Dressing moistened with salt solution.

November 5th (two days). Grafts look pink. First dressing.

November 13th (ten days). Daily dressing since November 5th. Grafted surface has reached the level of the surrounding parts. Difficult to distinguish the original boundaries of the ulcer.

November 15th (twelve days). Whole surface covered with a layer of epithelium.

November 20th (seventeen days). Surface covering looks like true skin. Patient has gained greatly in weight and strength. Rubber strips omitted, and corrosive sublimate dressing applied.

November 24th (three weeks). Grafted surface completely healed over, and seems firm and strong. Patient up, and walking about ward.

#### A CASE OF ACUTE ENDOCARDITIS.<sup>1</sup>

BY FREDERIC W. TAYLOR, M.D., CAMBRIDGE, MASS.

A. B., MALE, aged thirty-one, American, of German parentage, foreman. Parents, brothers and sisters living and well. Married recently. When seventeen years old had gonorrhœa and syphilis. Since then he has usually been very well, and during the past few years his habits have been exemplary.

During the first part of the week beginning August 10, 1890, he suffered from diarrhœa and malaise. A

<sup>1</sup> Read before the Cambridge Medical Improvement Society, November 24, 1890.

temporary improvement followed, but Thursday, August 14th, the headache increased, and he went to bed. Antipyrine was repeatedly taken with but temporary relief. When first seen by me August 16th, the temperature was  $103^{\circ}$  F., pulse 100. The only symptom complained of was cephalalgia, which was severe every afternoon, and which was subsequently readily relieved by ordinary doses of Dover's powder. There had been no chill; mind clear; tongue moist. Milk was taken in abundance, and with relish. The bowels at this time were somewhat constipated, so that during the next week an occasional enema was given. On the 16th, 17th and 18th of August there was an evening rise and morning fall of temperature, with corresponding exacerbation and remission of symptoms. During the week following the 18th, the symptoms were not severe, and only a single daily visit and observation were made till the 26th. During this time the headache gradually abated, and as the opiate was consequently diminished, the bowels acted spontaneously. The abdomen was normally full, at no time tense, nor unduly tympanitic, though at times painful, as if from intestinal colic. The splenic region alone was tender, and the area of splenic dullness enlarged. There were no rose spots at any stage of the illness. A soft systolic souffle was to be heard at the apex of the heart. Subsequent to the increase of respiratory rate, which began on the 24th of August, and reached forty a minute on the 25th, moist râles were heard over the entire chest, but most numerous on the right side, where within a few days they became very abundant. Delirium was occasional, was very mild, and occurred only during sleep, or immediately upon waking.

August 31st, mind less clear, strength evidently failing. Respiration and pulse rapidly increasing in rate. September 1st, diarrhoea: at least four liquid dejections of light brown color. After this date there were three to eight liquid dejections daily, many of them involuntary. September 2d, a few petechial extravasations over abdomen and back. During the next few days the number of these increased greatly. This day the temperature dropped five degrees, to  $100^{\circ}$  F. September 4th, about five o'clock p. m., the patient was found to be very cold, though he made no complaint. During the evening the temperature rose to  $103^{\circ}$  F. September 5th, left thigh and leg cold. No pulsation below left groin. Late in the evening the temperature was above  $106^{\circ}$  F.; pulse, 160. Death took place September 6th, 5 a. m.

The urine throughout had the usual appearance of fever urine; at times voided with difficulty or at least delay, but in good quantity.

The treatment was purely symptomatic. Liquid nourishment, chiefly milk, was taken in abundance. Stimulants, alcohol in various forms, carbonate of ammonia, aromatic spirits of ammonia; digitalis; opiates — at first for pain — toward the last to check diarrhoea, or allay restlessness.

Autopsy, September 8, 1890, 9.30 A. M., was somewhat hurried because of objections of friends to any but a brief examination. Body had been embalmed. Rigor mortis present. Numerous pet. ch. over trunk and upper extremities. Left lower extremity larger than right. Head not opened. Lungs retracted when chest was opened; crepitation throughout, but diminished in posterior portion of right lung; moderate hypostatic congestion. Heart, mitral and aortic

valves covered by a luxuriant growth of soft vegetations in which were entangled small, fresh clots; otherwise normal. Spleen enlarged to about twice its normal bulk; dark red; soft. Kidneys and liver showed acute granular degeneration. Intestines (most of which were removed and subsequently thoroughly looked over): numerous small hæmorrhages similar to those in the skin, but larger and less definitely bounded; more evident on the mucous side than on the peritoneal. No ulceration was found though carefully looked for. A few single follicles were prominent, some at the centres of extravasations, in which case there was often a loss of epithelium at and immediately about the gland, but no considerable loss of substance.

Riding the fork formed by the division of the left common iliac artery was a firm fibrinous plug, which completely filled the vessel, and from which branches extended into the external iliac and internal iliac.

To recapitulate: A healthy man, aged thirty-one years, suffered from acute febrile symptoms coming on without chill, from severe headache and moderate diarrhoea. The temperature rose to between  $103^{\circ}$  and  $104^{\circ}$  F., at night, was one and a half or more degrees lower in the morning. The diarrhoea was of brief duration and not severe. The headache gradually disappeared. In the middle of the second week the respiratory rate rose from twenty to forty a minute, and moist râles appeared in abundance in right lung. A soft systolic cardiac souffle existed. The symptoms remained much the same till toward the end of the third week, when they became aggravated: the respiration forty to fifty, the pulse 120 and over, the temperature very variable, one evening  $105^{\circ}$  F., the next  $100^{\circ}$ . At this time diarrhoea reappeared. Toward the end of the fourth week the pulsation suddenly disappeared from the left lower extremity, and death followed twenty-four hours later. The autopsy revealed enlarged spleen, granular degeneration of the parenchymatous organs, small extravasations in the skin and intestines, abundant vegetations on the mitral and aortic valves, and a completely obstructing embolus in the left common iliac artery.

Two consultants were called to the case. One was in daily attendance for six days, the other for two days previous to the death of the patient. Both expressed agreement with the attendant, who thought the case to be one of typhoid fever. With the added light of the autopsy what diagnosis shall we make?

Of the existence of endocarditis verrucosa there can be no doubt, and that this process was acute is highly probable, from the absence of symptoms previous to the present illness. Valvular disease of the degree found in this heart would undoubtedly have given some indication of its presence.

The embolism of the left common iliac artery was, of course, a direct result of the endocarditis.

The question that chiefly concerns us is, what was the primary disease? Was it endocarditis? or was the endocarditis secondary to some infection, or septic affection?

Dr. A. L. Loomis<sup>2</sup> writes, "acute exudative endocarditis is rarely, if ever, idiopathic."

Strumpel<sup>3</sup> writes, "Endocarditis, therefore, in its ætiological relations is not to be regarded as a single disease; infectious agents of inflammation especially, if

<sup>1</sup> Pepper's System of Medicine, vol. I., p. 670.

<sup>2</sup> Text-book of Medicine, p. 27.

not exclusively, seem to be its cause." He then enumerates as causes, acute rheumatism, chorea, the exanthemata, typhoid, small-pox, phthisis, septic and pyæmic diseases, and as a favorable condition for its development chronic endocarditis.

Niemeyer<sup>4</sup> is of much the same opinion. "Whether primary idiopathic endocarditis ever occurs, and whether the disease independently can attack a previously healthy person who has been exposed to cold may be doubted, yet it is not impossible." Niemeyer gives a list of causative diseases which is included in that just given, taken from Strümpel's book.

In addition to the views above expressed, the course of the illness might well lead us to think that its nature differed at different stages. The regular daily remission of symptoms during the first week or ten days, and the regularity of the changes in temperature and pulse-rate on the 17th and 18th of August (the only time in the early part of the illness in which we can exhibit a definite chart), contrast strongly with the irregularity of symptoms and chart of the last week, while the sudden and great increase in the rate of respiration at the end of the second week is suggestive of the time at which a new element was introduced into the case.

What, then, was the disease which *first* attacked our patient?

The clinical aspect of the case was such that the attending physician had no doubt that it was typhoid fever, and the consultants agreed with him in that opinion. The indications pointing to typhoid were the diarrhoea, which, though it lasted but a short time at the beginning of the sickness, reappeared toward the end; the severe afternoon headache; the daily variations of temperature; the enlargement of the spleen; and the absence of symptoms distinctive of any other disease. Yet in view of the facts that the autopsy, made after the disease had been in progress nearly four weeks, discovered no intestinal ulceration, and no evidence of there having been any, and that during the entire course of the disease no rose spots appeared, I believe we are not justified in making that diagnosis, however loath we may be to surrender an opinion confidently held before the patient's death.

Of the other diseases enumerated above as being primary to acute endocarditis, acute rheumatism, chorea, the exanthemata, nephritis, small-pox and phthisis may be dismissed for lack of evidence in their favor. The last of the list is septic and pyæmic diseases. When sepsis or pyæmia is present the place at which the infection entered is usually evident, the womb after child-birth, an open wound after an injury, or some internal lesion, as an intestinal ulcer of typhoid fever. At times, however, the entrance point is obscure, and Strümpel even recognizes cases in which there may have been no lesion, to which he gives the name "spontaneous septicopyæmia." In the present case there certainly was no *evident* lesion to serve as the starting point of septicæmia. Spontaneous septicopyæmia is rare, and we must, therefore, have strong evidence in its favor before declaring it, and that we certainly have not here; for a septic disease is usually sudden in its onset, ushered in, and accompanied by chills, has a very irregular temperature chart, and, especially when severe enough to be fatal, and when complicated with endocarditis, presents multiple metastatic abscesses; symptoms which we look for in vain

in the present case. Therefore, that diagnosis, while possible, is not certain nor satisfactory. The numerous extravasations alone are in its favor, but as these did not appear till toward the close of the sickness they throw no light upon its origin.

After thus wandering about in vain search for a diagnosis, we come back to that of which we are certain, acute endocarditis, and ask if that may not account for all the symptoms. Idiopathic inflammation of a serous membrane is not the rule, but with our present limitation of knowledge I believe that we must still admit that it occurs. Endocarditis raises the temperature and increases the rate of pulse and respiration, and gives rise to symptoms which regularly accompany the condition we call fever. This we know from our observation of it when it occurs in the course of some other disease, for example, acute rheumatism. The temperature rarely rises above 103°. There may be subjective symptoms referred to the cardiac region, but often they are absent. A heart murmur usually exists if the valves are affected, but this may not be present, or may be very soft. In the case reported the murmur was supposed to be of hæmic origin.

In general, there are recognized two forms of acute endocarditis, the exudative and ulcerative, the latter usually septic. Ulcers may form because the exudation takes place so rapidly and so abundantly as to cut off the nutrition of the endocardium overlying it; or the exudation may be purulent, and cause abscesses which rupture the endocardium.

May it not be that the case before us began as a non-septic endocarditis resulting in the formation of vegetations; that the process gradually increased in severity (and the process must have been very active, as shown by the profusion of vegetations) until it took on a septic character, which accounts for the irregularity of the chart, the diarrhoea, and the multiple extravasations occurring during the last five or six days? Finally, a large mass was torn from the vegetations, and the consequent plugging of the left common iliac artery was the immediate cause of death.

I offer this explanation as the best I have been able to make of this very interesting and puzzling case, and trust you may suggest improvements on this, or another entirely different that may be more satisfactory. I have to regret that more detailed notes were not recorded during the progress of the case.

## New Instruments.

### IMPROVED APPARATUS FOR STERILIZING SURGICAL INSTRUMENTS AND DRESSINGS.

BY ERNEST W. CUSHING, M.D., BOSTON.

The inconveniences connected with the methods of sterilizing surgical instruments by immersing them in antiseptic solutions, or by boiling them, have led to the introduction of apparatus for the use of dry heat as a sterilizing agent, the only difficulties to be overcome being the regulation of the temperature, and the even distribution of heat throughout the apparatus.

The oven shown herewith was purchased in Berlin last summer, and may be described as follows: There is a triple metallic box, covered with layers of asbes-

<sup>4</sup> Text-book of Practical Medicine, vol. 1, p. 329.

<sup>1</sup> Read at the Meeting of the Surgical Section of the Suffolk District Medical Society, December 3, 1896.

tos, and with doors opening on the front. In the free space, C, between the two outer layers, gas mixed with air is burned in a long row of small flames, F. The vapors from the flames pass out by a chimney, S, after circulating around the oven. The draught thus created causes fresh air to pass in at the bottom of the apparatus at R, the air is heated greatly in passing between the two metallic surfaces outside of the cavity of the oven and inside of the chamber where the flame is, K. This hot dry air then enters the oven from above, surrounds whatever may be in it, and passing below K, goes, already hot, to feed the flame before finally escaping. A mercurial regulator, and a thermometer, enable the temperature to be kept at any given point:  $150^{\circ}\text{C}$ ., equal to about  $300^{\circ}\text{F}$ ., is a temperature sufficient in one hour to thoroughly sterilize the contents of the oven, without injuring steel, annealed glass, or dry catgut, cotton, woolen or silk.

It is thus possible to pack in a metallic box nearly everything which it is necessary to use at an operation; such articles may then be sterilized altogether in the box, and the latter need not be opened until the very moment of operation. I show here such a box which I have had constructed for use at laparotomies, fourteen inches long, ten inches wide and two inches high. This contains two trays, in the upper of which are laid all the instruments likely to be wanted, while in the under one are some which may possibly be needed. The abdominal bandage, absorbent cotton, and gauze, for the abdominal dressings, are all laid in the lower tray; there also are needles ready threaded with silk, envelopes containing dry catgut, cut in proper lengths for use; a separate envelope contains fine needles already threaded with silk, and such other things as may be needed in case it be necessary to suture the intestine; three glass drainage tubes of various lengths complete the outfit.

Of course it would be easy to arrange a box for any other operation, such as a trephining, an amputation, or an operation on bone, and it is easy to see the great amount of labor which is saved by the fact that no instrument is wet or soiled which is not actually used, while the hands of the surgeon are spared the consequences of repeated immersion in carbolic solution, and the injury to the instruments, which is inseparable from boiling, is avoided. The advantages which are claimed for this oven over all previous ones are, first: that sterilization is accomplished simply by a current of hot air; second, that the bottom is not excessively heated, and the temperature throughout the oven is the same; third, that the finest instruments

are not injured in point or edge, and they may be laid anywhere on the shelves in the oven without special protection; fourth, that with consumption of very little gas, the full temperature of  $150^{\circ}\text{C}$ . may be obtained within twenty minutes; lastly, that this apparatus may be used for sterilizing other things besides instruments and dressings. For example: a suit of clothes which has been worn where there is infectious disease, may be folded, laid in the oven, and baked without injury to the fabric.

The other apparatus shown to-night is an improved form of sterilizer where steam is the agent employed. It is extremely convenient for use in a hospital in making preparations for operations, as by this we can rapidly sterilize the clothing, sheets and blankets to be used at an operation, the robe of the operator, the towels which are to be placed around the wound, and wads of absorbent gauze, which take the place of sponges.

In this apparatus a double, cylindrical kettle of copper is enclosed in an iron jacket, so that the heat from a large Bunsen burner passes all around the kettle. A heavy cover, lined with felt, and fastened with three screw clamps, closes the kettle, steam tight; a gauge in front shows the amount of water present; metallic cylinders of different lengths are provided to hold whatever is to be sterilized. These cylinders have closely fitting covers, and two movable bands near the top and the bottom. The bands and cylinders are pierced with holes; by this means when they are in the sterilizer the steam can penetrate throughout the cylinders, and when the latter are taken out the holes are covered by slipping the bands sideways, and thus no germs can enter. The space between the two walls of the kettle is partially filled with hot water, one or more cylinders with their contents are put in, the cover is screwed on, and the lamp lighted. The steam which is generated passes into the inner kettle, through a row of holes near the top and streaming through the cavity, it passes out near the bottom through a lead tube coiled in a vessel of cold water. The articles to be sterilized are thus kept in a current of steam at a temperature of about  $214^{\circ}\text{F}$ ., which can be increased a little by carrying the end of the lead pipe deeper under the water. Very perfect sterilization may be obtained in half an hour by the use of this apparatus. The articles which have been steamed seem hardly damp when taken out, and by using one cylinder for towels, an abundant supply of these, perfectly sterilized, is available at operations. Similarly with the wads or pads of gauze, which take the place of sponges; these may be carried to the scene of operation in the same cylinder in which they are steamed, and used with the greatest confidence in their aseptic condition.

It is well known that dry gauze is a much better haemostatic than a wet sponge, and by the use of the former and of dry steamed towels a great deal of unnecessary sloppiness is avoided at operation, and the patient is kept dry and clean.

Every surgeon, who has conscientiously prepared his own instruments, and his sponges, for operations, will realize the immense amount of time and labor saved by the use of the apparatus above described, which I shall be pleased to show in action, to those specially interested in the subject, at the Woman's Charity Club Hospital, No. 38 Chester Square, Boston.

## Reports of Societies.

### SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

GEORGE H. MONKS, M.D., SECRETARY.

REGULAR meeting, Wednesday evening, December 3, 1890, the Chairman, DR. A. T. CABOT, presiding, and DR. H. W. CUSHING acting as Secretary for the evening.

DR. PAUL THORNDIKE presented a communication entitled

#### NOTES ON SKIN-GRAFTING,

and showed a case which had been operated upon by Thiersch's method.<sup>1</sup>

DR. F. S. WATSON: It happened that while Dr. Thorndike was writing this paper, I had my first experience with Thiersch's method, the result of which you have seen in this case. I had expected to be pleased with the method from what I had heard of it, but was not prepared for the surprisingly favorable result which exceeded all anticipation. To have a surface of this sort which has failed to heal in weeks, and as in many other cases reported in months, covered solidly with skin in ten to fourteen days, represents one of the most brilliant surgical advancements, it seems to me, we have seen in recent years. There is nothing to say in addition to what Dr. Thorndike has said in regard to the method of carrying out the treatment which is simple. I was rather surprised at the ease with which one could shave off exceedingly thin strips of skin from the thigh stretched tight, and I found no difficulty in getting enough to cover the ulcer with pieces of skin about as thin as note paper.

This method has the advantage of doing away with the deep wounds resulting in certain plastic operations. This seems to me one of its greatest advantages. I recently employed it again in the case of an axilla which was entirely bared from the elbow to a corresponding point on the side, and in that case it was shown that to be successful you do not need to cover the whole of the space, and that you need not scrape or shave off the granulations. The patient was not in very good condition, and the surface exposed enormous, and the bleeding was to be spared as much as possible, so that only a partial operation was done, with entire success as far as it went.

DR. MIXTER: I have been much interested in the subject of skin-grafting ever since I was interne at the Massachusetts General Hospital. While there I had an opportunity to try the ordinary method of grafting on a number of cases, obtaining about the usual results. The grafts would often be floated off by the pus and disappear. During the service of Dr. Samuel Cabot I was given an opportunity to graft an ulcer in the popliteal space, six by three inches. With curved scissors I cut from the thigh long, thin strips of the superficial layer. These strips were then cut up as small as possible and the pieces planted thickly over the ulcer, each piece being thrust deep into the granulations. In this way the ulcer was sprinkled with very minute grafts, about two hundred and fifty being used. The ulcer was entirely healed in about a week.

This method of using a great number of very small grafts is a distinct improvement over the original operation.

About three years ago there was admitted to the Massachusetts General Hospital in Dr. Richardson's service, a woman whose scalp had been completely torn off. The scalp was carefully stitched in place, but failed to unite. After the head had begun to granulate I was asked to try grafting, which I proposed to do with a large flap from an amputated limb. With the idea of preventing the flap from being floated off by the pus, I punched it full of holes, after shaving it as thin as possible on the under side. In order to punch these holes more quickly I made a sort of battery punch with which sixty-four holes could be made at once.

A foot amputated for railroad injury was skinned and the skin, treated as above described, was stitched to the skin surrounding the granulating surface, completely covering it with a sort of network. Only the parts projecting over the sound skin sloughed—the rest appeared in good condition and vitalized for at least ten days, and the interspaces made by the punch cicatrized. Then, owing perhaps, to the use of too strong antiseptics, or to the scanty blood-supply and poor condition of the patient, the flap began to disappear, and in a few days nothing was left of it; it did not slough but melted away.

This method will succeed, I am sure, in certain cases, but it is very seldom that suitable skin can be obtained, even in an hospital.

These very successful cases of Dr. Watson's show what an advance Thiersch's method is over all previous ones. The results obtained, even in cases of chronic ulcer of the leg, are most remarkable, and as Dr. Watson has said, this method greatly simplifies plastic surgery, as the resulting tissue has little tendency to contract. In New York and Baltimore I have recently seen many cases of both immediate and secondary grafting after the removal of tumors, etc., with most satisfactory results.

DR. JOHN HOMANS and DR. G. L. WALTON reported

#### A CASE OF SUCCESSFUL TREPHINING FOR CEREBRAL HEMORRHAGE PRODUCED BY CONTRE-COUP.<sup>2</sup>

DR. WARREN: I think this contribution is valuable just at this time when so much interest is taken in cerebral surgery, and undoubtedly the more attention we give to such cases the more cases surgeons will see which are capable of being helped by surgical interference.

I saw a case the other day, somewhat similar in its pathological conditions to that reported. I was sent for to go to the hospital for an accident. A man had been picked up on the railroad track. The nature of the accident was unknown. There was a cut on the centre of the forehead, just above the glabella. The patient was comatose. No information of any kind could be obtained. There was right hemiplegia. It seemed improbable that the hemiplegia was caused by any blow such as he had probably received where the cut was, as this was over the frontal sinuses, and, as it afterwards proved, it was a depressed fracture into the frontal sinuses, and did not communicate with the brain at all. Without knowing Nancré's views, which Dr. Walton has quoted, I decided to explore the motor region of the left side near the fissure of Rolando, and ordered the house-officer to shave the head for that purpose. While the shaving process

<sup>1</sup> See page 157 of the Journal.

<sup>2</sup> See page 153 of the Journal.

was going on, the hemiplegia, which was quite complete before that, began to disappear. The man began to move his hand, wrist and leg. Under these circumstances it did not seem to me advisable to put on the trephine. I said "we will explore the wound in the forehead, and if that throws any light on the condition in the interior of the brain, we will go farther if necessary," but it did not, and consequently nothing more was done. To make the story very short the patient made a good recovery, and went home some three weeks after the injury with the wound in the forehead healed. Dr. Walton saw the patient, and I think he can give you some facts with reference to the return of motion. There was on the second day a slight attack of Jacksonian epilepsy, and I think some slight indications of another the day following, and I asked Dr. Walton if he would watch the case, and I added that I was prepared to interfere at any moment. But the moment did not arrive, and the clot which was effused was subsequently absorbed. The question which Dr. Walton raised in conversation with me was as to what might be the subsequent results of a clot of that size (sufficient to produce a hemiplegia) on the future welfare of the patient, and whether or not it was advisable in these light cases to trephine in order to leave the parts in as normal a condition as possible, and to leave no chance for inflammation of the dura, or of a cyst formation, or of other conditions of inflammatory nature which might give rise to persistent headache. I have recently had a case somewhat near the same region on the skull where there was no actual depression of the bone, but an indentation of the outer table only, and where adhesions of the dura to the skull occurred, and some inflammation of the dura, and trephining was necessary, for the relief of persistent headache, four years after the injury, although at the time there were no motor symptoms. It was supposed to be merely a scalp wound. How far then we are justified in operating for the sake of avoiding future pathological conditions is a question which is to be studied out carefully.

In regard to the technique of operations for trephining, etc., I would say that I found in some of my cases difficulty in getting the scalp wound healed entirely, particularly when the drain has been left in. If the patient is allowed to go about and the dressing is taken off, there is danger of relapse. One is uncertain as to what may happen to the patient, if the wound is left undressed. There is, therefore, now a tendency to seal up the wound entirely without any drain, and the incision by first intention. I have recently done this with satisfactory results, in a case a few weeks ago, and healing took place at once.

Dr. KENNEDY: Before the discussion goes any further, and before the neurologists discuss this paper, I would like to ask their attention to that part of the subject, which pertains to the indications for trephining, that is, as to where the line is to be drawn which could separate a case where trephining certainly ought to be done from one where it ought not to be done. As I came under my observation very similar history and symptoms, to that presented this morning, but not, however, so definite a case for intervention. It was carefully watched for a long time, and no operation was performed. Not having the record of the case with me, I cannot give the details. I think Dr. Walton saw the case, and I know that Dr. Putnam and I have each ever since that I may not have

given this man the best chance for recovery. He recovered, however; but I have not heard from him since he left the hospital.

Dr. KNAPP: As to the point which Dr. Richardson has brought up, I intended to speak before he suggested it. I think that every one will admit that in cases of meningeal hemorrhage we should trephine, and remove the clot. There are two questions, however, that come up. The first is one which Dr. Warren has broached, namely, where the symptoms are slight and there is probably only a very slight hemorrhage, should we trephine? I would say, in answer to that, very briefly, that my feeling would be to trephine, but I will return to that point later. The second point is in regard to the diagnosis of meningeal hemorrhage. Of course, there are a good many cases where we feel reasonably sure, but there are other cases where there is no history, where a man is picked up unconscious, and we find him paralyzed.

Here the question must arise. Is there a meningeal hemorrhage due to some injury, or is there an intracerebral hemorrhage or thrombosis or embolism which has come on perhaps secondarily to some slight injury, or perhaps spontaneously, and any injury, if injury there be, is secondary to the hemorrhage? That is, the man, having an apoplectic stroke, falls unconscious and perhaps cuts his head as he falls. In such cases we get some little help by the presence of Jacksonian epilepsy, by the unequal pupils, by the slowly progressive character of the paralysis or of the coma, but none of those are absolutely decisive. In such cases I believe if there is a fair suspicion of a meningeal hemorrhage or of an injury, it is well to trephine for the purpose of diagnosis, the operation itself not being particularly serious, not adding very greatly to the danger, while the chance that the hemorrhage is meningeal, and the possibility of removing the clot, certainly justifies the risk. If the hemorrhage be intracerebral then, of course, nothing can be done, and it has taken something from the patient's chance of recovery. If the hemorrhage be meningeal it gives him an excellent chance of recovery. So much for the question of operating in meningeal hemorrhage. To return to the point which I previously referred to, of operating in slight cases, that would come under the consideration of operating in cases of fracture. In the discussion of a paper which Dr. Porter read last year, several of the neurologists present, myself among them, advocated trephining in certain cases of fracture, because we saw more than the surgeons did the bad results from fractures, the epilepsies, the dementias, the persistent headaches that come on after old fractures. Furthermore, the case Dr. Warren reported in the *Journal of Medical Sciences* last spring or winter shows the advantage, in fractures of the base, of trephining for drainage; but the opinions hinted at then have been more than confirmed by Mr. Horsley this summer, when he said that every case of fracture of the skull should be trephined. Therefore, to avoid the risks of a small clot retained in the cranial cavity, I think we should trephine in the cases of mild hemorrhage.

In regard to what Dr. Walton has said concerning Jacksonian epilepsy, although it is most distinctly a valuable symptom, I think we should be cautious of making too definite a diagnosis from that symptom alone. The investigations of Sepilli and Löwenfeld and the recent paper of Oppenheim on brain tumors

show very conclusively that Jacksonian epilepsy is not by any means an absolute localizing symptom.

Dr. Walton has referred briefly in the beginning of his paper to the question of operating for tumors. I would agree with him upon his estimate of the percentages, and upon the very limited field for such operations. There are, however, two points that I should like to bring forward. The first is his suggestion that gummata are hardly to be operated upon, and with that I am disposed to disagree because I do not believe you can get a gumma absorbed by any amount of mercury or iodine without leaving a good deal of connective tissue there which will act in the same way as the gumma. The opinion of a number of neurologists and of Mr. Horsley is that the gumma should be removed like any other tumor.

The second point which Mr. Horsley urged this summer, I spoke of at the meeting of the Observation Society, last October. In the cases of brain tumor where the local diagnosis is not possible, or where the tumor is probably a malignant growth or so thoroughly infiltrated that it cannot be removed, or where the local diagnosis is possible, and it is in a situation that renders it impossible to be removed, and where there is intense and persistent headache, there Mr. Horsley says, and he substantiates it by successful results in four cases, that the patient should be trephined to relieve the headache.

DR. BULLARD: As to the question asked by Dr. Richardson, it seems to me that we can draw a more or less definite line in regard to those cases of middle meningeal hemorrhage which should be trephined in this way. Trephining is no longer so serious an operation as it was at one time, and it may be considered in many cases only a moderately serious, or perhaps you may say slightly serious, operation. For this reason it seems to me, that, in any case where the diagnosis of hemorrhage of the middle meningeal has been made and the symptoms are serious in character, threatening the life of the patient, and where there is nothing to absolutely contraindicate an operation, that trephining should be done. It seems to me that in all other cases of moderate severity, but not threatening the patient's life, which remain persistent for a considerable length of time, such as persistent hemiplegia, operation should be done. On the other hand, where the symptoms are slight and where there is reason to suppose they may shortly disappear, it seems to me we should wait a reasonable length of time. I am not inclined to agree with those who believe that every fracture of the skull should be trephined at once. It seems to me that there are many cases in which it is advisable to wait.

In regard to the localization in these cases, it is sometimes a simple matter; but, on the other hand, it is not infrequently very difficult to determine even on which side of the brain we should trephine. It is probable that in a very large number of cases where there is a fracture (and this fracture may not be always in the outer table or apparent), there is more or less contusion of the brain on the other side. A large number of autopsies have lately been published in which contusion was found in nearly every case in the opposite temporo-sphenoidal lobe. I saw a case a short time ago in which there was considerable difficulty in the localization. The patient was injured one evening, struck on the head with some hard substance, and after the blow was able to walk some distance get his head dressed

and go home. The next morning he was found unconscious and brought to the hospital. I saw him the fourth day after the accident. He had been entirely unconscious from the moment of entrance to the hospital. There was no marked paralysis anywhere, slight nystagmus was the only other symptom. There was a small incised wound on the right parietal bone, but no evidence of fracture could be found. It was thought by the gentlemen in charge, and those who had an opportunity of watching him that the limbs on the right side were a little weaker than those on the left, but nevertheless there was movement in the extremities on both sides. The question was where to trephine. After examining the case thoroughly it was decided that trephining was advisable, inasmuch as the patient was in a somewhat dangerous condition and it was decided that the slight paralysis on the right side must be neglected. The operation was performed over the place of the incised wound. There was no fracture of the outer table of the skull, but there was fracture of the inner table, and the clot was found underneath and removed. I give this simply as an illustration of some of the difficulties in localization.

There is one surgical question that I should like to speak of and inquire about. What measures should be taken to prevent secondary hemorrhage? In one case in which I had the opportunity of seeing the autopsy, the death was unquestionably by secondary hemorrhage. The clot was removed and the artery within twenty-four hours began to bleed again. The fracture was at the base of the brain.

DR. RICHARDSON: I am very glad to hear the opinions expressed by Dr. Knapp and Dr. Bullard. I must say that I don't agree with Dr. Knapp in the only part of the subject with which I feel familiar, and that is the question of trephining. I agree that the lifting of a fragment from the dura mater is not a dangerous operation. I think, however, that when the dura mater is opened and the brain is exposed, it then becomes dangerous, and I do not think we are justified at present in doing a dangerous operation for a slight hemorrhage. I agree with Dr. Bullard in that respect. Dr. Bullard has mentioned one case of trephining, which resulted fatally. I think every case in which I have opened the dura mater has been fatal, and with such an experience I feel as if there was considerable danger in operations where the brain is exposed. I dare say it was my fault, but I am one surgeon, and that is my experience, and the collective experience of all surgeons will be the average; and we have to consider the average amount of skill and average amount of success, and therefore at present it seems to me that for slight symptoms and slight hemorrhage we cannot feel justified as yet in opening the dura mater. In the case I referred to in which there were decided symptoms of pressure, in which also, as I remember it, the neurologists were doubtful as to the exact localization, I felt that the safe course was to let the matter rest. I dare say I was wrong about it, but there certainly must be a line somewhere; there must be hemorrhages so slight that they can be disregarded, and on the other hand we ought not to refrain from operating in other cases where the symptoms are somewhat severe. I dare say the neurologists see more cases of cerebral irritation from depression than the surgeons do, and yet when we remember how many cases come to the surgeon and how few are referred back by the neurologists for operations for

secondary symptoms, the number is very small; and yet the more I see of surgery the more I am coming to that opinion that depressed fragments upon the dura mater ought to be lifted.

DR. KNAPP: I did not mean to say that every fracture of the skull is going later to develop epilepsy or persistent headache or dementia, but a certain number of these cases do: which cases will and which will not we are not yet in a position to say, and until we are able to decide, I think we should be on the safe side, and save patients from the fate of epilepsy.

As regards opening the dura I can speak simply from my own experience this last spring. I had two cases which were operated on by Dr. Post. One case was a girl with a depressed fracture in the forehead, close to the longitudinal sinus, and six or seven years later she developed epilepsy. If she had been trephined when first injured, when she lay in the hospital in Ireland, I believe she never would have had epilepsy. She was trephined. The scar was close to the longitudinal sinus and thickened membrane was found. A part of the thickened dura was removed, cut as close to the sinus as possible without going into it, and a little brain substance was removed and that patient two days after the operation was sitting up in bed reading; and in six days she was walking about the ward.

The second case I reported last June to the Neurological Association. It was that of a man who had a slowly developing dementia, and symptoms of general paralysis after injury to the head. After trephining and removal of a small portion of the dura and of the brain substance that man did, uninterrupted, well. He stayed in bed about three weeks, not necessarily, but by a mistake, my orders being misunderstood. These cases show that opening the dura is not always fatal. Of course my personal familiarity with operation on the brain is rather slight. I do not see what particular additional risk you get by opening the dura provided you are doing an aseptic operation.

DR. BIXBROOK: I think we would all agree with Dr. Richardson that the opening of the dura means greater danger than not opening the dura, but does he not exaggerate the danger of trephining where the dura is not opened? I understand Mr. Horsley's position to be this: that the surgical world to-day is in danger of overlooking cases that could be saved after exploratory trephining. If there is no bulging of the membrane and no intracranial pressure it can readily be seen that the risk of trephining without opening the dura is not very great. If there is intracranial pressure, the risk of leaving such cases untreated is great. In regard to our not seeing these cases of fracture and the epilepsy that follows, it may, I think, be explained in this way: that these cases wander to other institutions. The classes of cases that come to the hospital are the floating population. A man may have an operation here and go out West and have his epilepsy there. I am inclined to think that a fracture of the skull is more of an injury than we sometimes think.

DR. RICHMOND: I think I was misunderstood in regard to where the dura is not opened. I have trephined perhaps ten or fifteen times where the button has been raised from the dura without any difficulty at all. I appreciate more and more the dangers of leaving a fracture to itself. In the cases which I reported a number of years ago which were never published, the danger at that time was as to whether simple

fractures of the skull with depression, without symptoms, should be trephined. I think the opinion was rather against it then. I think we are coming to the opinion that depressed fractures generally should be trephined. I have just removed a depressed piece of bone from the frontal lobe right over the longitudinal sinus. A boy fell and received a compound depressed fracture ten years ago and was just beginning to get his epilepsy.

DR. ELLIOT: A year ago last summer I was with Mr. Horsley for about six weeks and saw him operate a good deal, and in that time he must have trephined ten or fifteen times, and there was not a single case that had a bad symptom. In all the cases he opened the dura without any ceremony at all. He, however, seemed to be more careful than any operator I have seen in handling the brain. He never injured the brain or explored it with trocars. He palpated very carefully with his fingers, and judged a good deal from what he felt. I think he never considered opening the dura as anything but a necessary part of every operation. I saw some of the cases of trephining for pain and headache, where the tumors were large and located in impossible places. He took out two buttons of two inches diameter on each side. He left the trephine hole full of blood and sewed up, and all healed by first intention. He thinks, and I should think, that it is entirely a question of asepsis, that you could open freely without danger if you really were aseptic. Speaking of the question of secondary hemorrhage and the methods of controlling it, I had a case last year while substituting for Dr. Homaus. It was a fracture of the base and opened into the lateral sinus, and a piece of the bone was pulled out and the lateral sinus bled freely. That was packed with iodoform gauze which controlled the bleeding fully.

DR. PORTER: I have been very much pleased in listening to the opinions which have been expressed to-night, having read a paper on the subject of trephining in cases of comminuted and depressed fractures, and I think as I recollect the discussion of that evening that the discussion to-night is very much in advance, much more in favor of operation in such cases without more definite indications, and I think that is due largely to the greater experience coming to various surgeons from the aid and advice of the neurologists in connection with trephining for the various troubles which I called attention to at that time, and which follow upon the injuries later in life.

In regard to the subject of controlling the hemorrhage I don't see why hemorrhage must not be controlled in this region as anywhere else. I reported, in connection with Dr. Marion some years ago a very interesting case where I trephined, and where there was very extensive hemorrhage indeed on the third or fourth day, so that when the wound was opened and the clot turned out, and it had to be turned out with a spoon, it was found that the whole anterior portion of the brain had been compressed backwards in a line almost vertical with the external auditory meatus, and the whole surface was oozing everywhere. I had never seen a case of the kind, and I had always been brought up to feel that everything foreign introduced into the cranial cavity under such circumstances was very injurious, and yet I thought then that there was nothing to do but to use compression, and I put in sponges with strings tied round them, numbering them so that I should know how to take them out;

and they remained in twenty-four hours; the bleeding still continuing, the sponges were put in again, and on their final removal the brain gradually came forward and filled up the cavity, and the man made a good recovery.

DR. BULLARD: In one of the cases which I have seen, the patient was in a dangerous condition entirely due to the compression, and if any other method can be found by which the brain can be relieved of the compression and at the same time the hæmorrhage can be controlled, it would be of the greatest service to the patient. As it was, relief from compression caused a great and rapid improvement in the patient's symptoms.

Dr. Richardson must have misunderstood my meaning if he thought that I intended to imply that the trephining in the case of hæmorrhage had anything to do with the death of the patient. The patient died, but I have been unable to learn whether the operation itself had anything to do with his death.

DR. HOMANS: I would only call attention to the fact that this was a case of trephining for hæmorrhage by contre-coup, and I did not enter into the case of trephining for the relief of fracture. So far as Dr. Walton and I know, this is the only successful case of trephining for contre-coup.

DR. WALTON: The most important point seems to be the practical question introduced by Dr. Richardson, as to just when we are to operate in these cases. It seems to me hardly satisfactory to follow any one absolute rule, such as, for example, in every case of supposed superficial hæmorrhage operate, or in every case of fracture operate. In case of punctured fracture I should always advise operation, as in every case of compound fracture, but in simple fractures I should be guided by the angle of the depression, by its amount, and by the severity of the cerebral symptoms, that is, the sharper the angle of depression, and the more marked the cerebral symptoms, the greater the indication for operation. In the same way regarding hæmorrhage, I think Dr. Warren's case shows the wisdom of deciding each case on its own merits. Here we had probably to do with a superficial hæmorrhage, but with one capable of absorption. The patient had a definite paralysis of the right arm. I remember tickling the cilia of the right eye when he was in a state of partial unconsciousness, and he would raise the left hand immediately to it, but would not move his right, which would have been a more convenient one. His grasp was weak and the right arm definitely paralyzed. I watched him twice a day regularly, ready to advise operation in case it seemed advisable. I said to Dr. Warren when I first saw him: that in case he became comatose, or in case convulsions came on of any severity, or in case the patient in any way should become definitely worse instead of better, I should operate; but instead of getting worse he continually grew better, and finally was discharged, I think, well. Now I think that illustrates the point. Of course, if we are sure that a hæmorrhage is now going on when we examine a patient with reference to operation, we certainly ought to operate and stop the hæmorrhage, but if we find the patient on the whole steadily improving, then it becomes an open question, and without any definite rule as to whether to operate or not. Here I think we have to decide in every individual case whether, on the whole, the final results of the compression, paralysis, for example, or the liability to future convulsions, will be severe enough to

justify our doing an operation which really is dangerous. There can be no doubt that it is dangerous, although opinions differ as to how dangerous it is. We must decide in our own case: would we care to undergo that operation and have a hole left in our skull, if we did not put the button back, which is always a source of some danger, although not great, and undergo the dangers of an operation for hæmorrhage, which we are not quite sure is on the cortex, or which may be absorbed spontaneously?

With regard to the question of drainage which Dr. Warren has brought up, I only view these cases as an observer, and not as an operator, and have hardly a right to opinion on that subject, but it seems to me the cases that had free drainage have got on better. The case that Dr. Richardson alluded to that he had last Saturday, although the dura was not opened, a fair-sized drainage-tube was put in, and I understand from Dr. Scudder that the temperature has not arisen since the day of operation above 98.6°. It is an exceptionally good recovery. When Dr. Keene wrote his article in 1888 for Wood's "Handbook of Therapeutics," he cited all the cases he could find in which drainage had been used and those in which it had not been used, or there was no record of it being used, and he found the proportion of recovery was much greater in those in which drainage had been used. Whether he has changed his views, I do not know.

DR. PORTER showed

#### TWO ENORMOUSLY HYPERTROPHIED BREASTS,

which he had recently removed.

DR. E. W. CUSHING showed

#### A FIBROID FORMERLY TREATED BY ELECTRICITY.

Although it had been punctured with electrodes, there were no adhesions. The places where the electrodes were said to have gone into it were not apparent.

#### IMPROVED APPARATUS FOR STERILIZING INSTRUMENTS AND DRESSINGS.\*

#### THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

The eighty-fifth annual meeting was held in the City Hall, Albany, February 3d, 4th and 5th, the President, DR. W. W. POTTER, of Buffalo, in the chair.

#### THE PRESIDENT'S ADDRESS.

The President said that it was the written law of the Society that its presiding officer should, at the opening of each annual session, make a communication setting forth the condition of the medical profession in the State, and make such suggestions in relation to its improvement as should be deemed appropriate. It was a fortunate circumstance that at this time there was in the condition of the profession much to commend and but little to criticize. If perfection had not been attained it was because they were human and because this was a progressive world and its purposes were accomplishing themselves in ever-widening circles.

The contribution of the State Society for this year

\* See page 161 of the Journal.

had been a State Medical Examining Board. This might easily be regarded as the most important step taken by this State within recent years in the direction of medical educational reform. They were now apparently near the realization of their long-desired deliverance from the thralldom of a system which had retarded the progress of medicine in the State more than all other causes combined.

If the present law was an apparent modification of the original bill which the Society had offered to the legislature who would dare to assert that it was not a better one. It was true that the original thought in the minds of many had been to obtain a single mixed Board, whereas the law contained provisions for three separate Boards, representing the three State Medical Societies recognized by the statutes of the State of New York. But let it be remembered that though there were now to be three Boards they were bound by a single standard in all the important and fundamental departments of the curriculum of medicine and moreover there was to be but a single licensing body, namely, the Board of Regents of the State of New York. Finally the medical colleges were all bound by the provisions of the law to give three full courses of medical instruction in different years before granting diplomas, since physicians would not be admitted to the examination for license with less preparation therefor. It might be that their enemies, who had appealed to all the weaker qualities of human nature to thwart the legitimate purpose of the measure, and had struck hands with any who could aid in bringing about defeat, had really aided this project more than we are aware.

The speaker concluded by urging that the law as it now stood should be accepted loyally, and that everything should be done to strengthen the hands of the Board of Regents charged with its execution. If, on due trial, there should be found defects, these could be remedied as experience pointed them out. As a final word he wished to urge upon the Society the importance of standing as a unit against any attempts to modify the present provisions of the law, or any endeavor to break its full effect until it was thoroughly tested.

#### NECROSIS OF THE RIBS COMPLICATING POTT'S DISEASE.

This was the title of a paper by Dr. L. A. WIEGEL, of Rochester. He thought the occurrence of necrosis of the ribs as a complication of Pott's disease sufficiently rare to merit record. He therefore narrated the following case:

Rebecca R. (colored), twenty-eight years old, had given a history of injury from falling on the ice, and wrenching her back, nine years before. She had previously been under treatment for lateral curvature of the spine, and while wearing plaster jackets, kyphosis of the seventh and eighth dorsal spines had developed. Soon after discontinuing the jackets an abscess had formed from which she had recovered. Some years after this an abscess had appeared in the left dorsal chest, just below the scapula, and this was opened. She had come under the immediate care of the speaker in July, 1889. He had treated the abscess, but without success and operative interference was accordingly undertaken. The old sinus was opened and the eighth rib was found to be extensively diseased as were also the sixth and seventh. The lower border of

these were serrated and undermined. The necrotic process had entirely destroyed the eighth rib at one point. The articular end was almost detached from the vertebra, and the articulation disorganized. To the left of, and parallel with the spinal column, a sinus extended downwards for about four inches. This was probably the remains of the lumbar abscess. The necrotic portion of the eighth rib was carefully detached from the underlying structures and resected. The carious portions of the sixth and seventh ribs were removed with the gouge forceps, a drainage-tube inserted and an antiseptic dressing applied. Since the operation the patient's general health had steadily improved.

When abscesses occurred in the course of Pott's disease the pus usually followed the line of least resistance and invaded the lumbar and psoas regions. Even when tubercular disease existed in the transverse processes, which lay posterior to the ribs it was uncommon for an abscess to appear in the lateral dorsal region, and hence infection of the surrounding structures was not likely to occur. In the case reported the disease of the ribs was undoubtedly secondary to the caries of the dorsal vertebrae, and was possibly due to an extension of the tubercular process by continuity. This, at least, would be a reasonable assumption with reference to the eighth rib, but the carious condition of the sixth and seventh at a point quite remote from the disease could not be explained in this way. Opinion differed as to the advisability of operative interference with the abscess and resection of the ribs.

#### BRIEF NOTES ON GASTROSTOMY, WITH REPORT OF A SUCCESSFUL CASE.

Dr. C. A. POWERS, of New York, read a paper with this title. The patient upon whom he had performed the operation was a man fifty years of age, who, from August of 1889 to February 1890, had continued to present more and more pronounced symptoms of stenosis of the œsophagus. Exploration of this canal had determined the existence of a stricture just about its cardiac orifice. Treatment by dilatation had relieved the urgent condition, and the man had been lost sight of for some months. On his coming again under treatment matters had become so serious that an operation was earnestly requested by the patient and undertaken by the speaker. Chloroform was accordingly administered, and a careful chart of the left lobe of the liver was marked out and an incision made parallel with the free border of the ribs, and about one inch distant from the costal arch. The incision was about two and a half inches in length, its centre being about one inch outside the free margin of the liver. The peritoneum being opened the hepatic margin had come into view. The fingers had then easily found the stomach, which was brought into the wound. The viscus was recognized by its size and surface vessels. It was fixed in the abdominal wound by six silk sutures passed through its peritoneal and muscular coats. Two loops of silk were inserted at the centre of the presenting portion of the stomach to mark the spot where the future opening was to be made. Antiseptic dressing of loose gauze was applied. The patient had reacted well and there were no untoward symptoms. Rectal alimentation was carefully maintained. The stomach was not opened till the fourth day. No pus was found at the seat of the original wound and the stomach was firmly adherent to the abdominal wall. The second

step was completed without anesthetics but there was no pain. A No. 9 soft English catheter was introduced through the incision into the stomach and two ounces of peptonized milk together with a little brandy were injected. The catheter was left in place, its end plugged, and it was fastened to the chest wall by a bit of plaster. As the patient got accustomed to this method of feeding, the rectal alimentation was gradually discontinued. During the first few months there was a marked increase in the body weight and a considerable improvement in the patient's general condition. After a time, however, the malignant growth had made such encroachments that the patient died of exhaustion incidental to the original disease.

The case afforded a fair illustration of the advantages derivable from gastrostomy in impermeable cancerous strictures of the esophagus. The life of the patient was prolonged for three months, and he was spared the agonies of death by starvation. In benign strictures the operation was undertaken with the view of saving life, and in malignant ones with the hope of prolonging it. Its statistics were far better than those for œsophagostomy or œsophagotomy, while œsophagectomy was worthy of no consideration. The use of the operation in benign cases would be limited to strictures which were impermeable. In permeable malignant cases tubage by the long nasal tubes of Krishaber or the short tubes of Symonds, seemed to offer the advantages of relief with freedom from danger. There must remain, however, a certain number of cases in which gastrostomy was the sole resource, and in these early and careful operation would prove of great advantage.

DR. MYNTER thought the operation ought to be undertaken with patient under cocaine anesthesia only, in view of the retching and vomiting always present with the other narcotics. He thought the suturing would be simplified by the use of Abbe's rings or Senn's plates. Abroad this operation was not considered very much of an achievement, and surgeons did it before breakfast.

DR. WILLY MEYER said the main point was to prevent leakage. If the patient was in a very low state or very old, it might be well to use cocaine. This drug would never produce any ill results if it was borne in mind that half a grain should be the maximum dose for hypodermic administration. He did not endorse the view that rings or plates were called for in this operation. He thought that if silk sutures were used the stomach might be opened at once. The best way to enter the stomach was to make a longitudinal incision through the rectus muscle and let it act as a sphincter.

DR. POWERS was sorry we had not over here the unlimited advantages offered to surgeons abroad in the matter of this operation. He could not feel that the use of cocaine would be proper, as the operation required a great deal of care and certainty that the stomach had been really found.

#### RAILROAD SURGERY.

This was the title of a paper by Dr. C. B. HERRICK, of Troy. He surveyed the whole ground of the injuries which, by reason of the special factors in their causation, presented definite surgical characteristics. He said that as to the prognosis in the more serious cases it was as favorable as in those occurring in civil

life. The railroad employees were, as a rule, young men, who from the nature of their work were rugged. Very little alcoholism was met with among them. In the case of civilians injured upon trains the prognosis depended upon the habits and age of the patients as well as upon the lesion. Then again, much depended upon the state of the injured person when brought to the operating room. Very often this was not done until much mischief had been incurred from rough handling and exposure of the injured parts to septic influences. Another point to consider was the question of shock, and to determine at what stage of the case to operate, whether in the primary, intermediate or secondary period. On this subject there was a great deal of difference of opinion. In the judgment of the author of the paper, if the patient was found to be in fair condition it was better to do at once any operation that was called for. By so doing the shock of the operation was modified by the already existing condition of shock, and to wait was only to further jeopardize life from hemorrhage and exhaustion.

DR. CHARLES A. POWERS, of New York, referring to a point touched upon by the previous speaker as to the conservative treatment of severe injuries of the fingers in men who had to earn their living by manual labor, said that it had been his experience that, though at the time of the injury these patients were always unwilling to undergo amputation of the member, still after a time, when they found that they had a stiff finger constantly interfering seriously with their work, they almost invariably came back and were glad to have the finger removed.

DR. HERMAN MYNTER, of Buffalo, criticised the review made by Dr. Herrick of those injuries which he considered as coming within the meaning of the term railroad surgery. He considered the term "railroad surgeon" a misnomer. They might just as well start an association of manufacturers' surgeons or heavy machinery surgeons. He had recently been called to a case of railroad injury, and had found three railroad surgeons quite at sea as to a diagnosis. They had about concluded that the man had peritonitis, that he had not long to live, and that to attempt his removal would only hasten his demise. The speaker had given it as his opinion that there existed no peritonitis, and had undertaken the removal of the patient after committing himself to a diagnosis of crushed kidney. Exploratory incision had confirmed this opinion. This was what might be termed a case of railroad surgery, and three railroad surgeons had been obliged to come to a civil surgeon for a diagnosis.

#### INJURIES TO THE KNEE-JOINT.

DR. H. FLOOD, of Elmira, in a paper on this subject, reported his treatment of a number of severe cases, and among them one of removal of the patella. His examination had revealed the fact that there existed complete comminution of the patella, and that the joint had escaped injury. Considerable, but not alarming, inflammation had set in and an abscess had formed in the synovial sac. The cavity was drained by two tubes. Complete recovery had resulted, and the patient had regained perfect use of his limb; there was only a slight halt in his gait. The speaker thought that the operation was a rare one, as he had been unable to find a recorded case in which removal had to be done for a traumatism. Of the cases he reported of injury to the knee-joint he said that part had been

treated before antiseptics was generally adopted. Others had been treated antiseptically, with results decidedly in favor of the latter precaution. All the cases illustrated the great principle that rest and thorough drainage were absolutely called for if a good result was to be hoped for.

#### ELECTRO-CAUTERY IN SURGERY, WITH SPECIAL REFERENCE TO ITS USE IN THE NOSE, THROAT AND MOUTH.

This was the title of a communication by Dr. D. H. GOODWILLIE, of New York. He said that of all the therapeutic means for the removal of hypertrophies and abnormal growths of any part of the body, but especially those of the nose, throat and mouth, the electro-cautery was of the most value, and would produce results which could not be so well attained by any other method of treatment. It was eminently superior to any caustic or cauterizing agent used in surgery; it could be limited in its action, quickly applied, and was entirely under control of the operator. For a successful use of electro-cautery as a means of treatment, it was not necessary to have a profound or technical knowledge of electricity. The electrical energy was now readily supplied with simple means of controlling the electro-motive force to any particular case in hand. The troublesome and vexatious primary batteries would soon be among the things of the past, and in their place the electrical power would be supplied in storage cells or used directly from the dynamo, the current being controlled by the will of the operator.

The speaker then exhibited a complete electro-surgical apparatus which he had made for special employment in surgical cases in any part of the body. He then went on to describe the apparatus, which consisted of a Piffard's combined dynamo and motor wound to take a 120-volt constant current, with a speed of 2,200 revolutions, which could be regulated by the candle-power of the lamp. Attached to the motor was a shaft and hand-piece for carrying the surgical instruments. The cautery was controlled by a rheostat, so that the smallest point electrode or platinum wire of six inches in length might be used. The speaker then proceeded to explain in detail the various instruments which formed a part of the outfit, and their adaptability to the special requirements of electro-cautery.

(To be continued.)

**THE LAWYER VERSUS THE DOCTOR.**—The Committee on Legislation of the California State Medical Society endeavored at the last session of the legislature to secure the passage of a bill requiring the plaintiff in a contemplated damage suit to furnish bonds for costs in the event of a "not proven." The chairman of the committee stated at the meeting held last April that the measure had been defeated by the senator from Los Angeles (a lawyer), who gave a reason that the enactment of such a law would discourage litigation.

*Druggist* (after heated discussion, to doctor).—I want you to understand that my profession as a druggist is as good as yours as a doctor. Our examinations are as severe, and, after all, what are you doctors but travelling salesmen to sell our goods?—*Harper's Bazar*.

THE BOSTON

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 12, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

#### TESTS FOR FREE HYDROCHLORIC ACID.

In two recent numbers of the *Centrablatt für klinische Medizin* (December 13 and 20, 1890), Günzburg and Boas have discussed the delicacy of the phloroglucin-vanillin and other similar tests for free hydrochloric acid. Phloroglucin-vanillin gives, with a trace of HCl, as the reader will remember, a beautiful red color when the mixture is carefully evaporated. More or less similar results are given by the reagent of Boas (resorcin and sugar), and by vanillin combined in various proportions with indol or resorcin (for example, indol 1.0, vanillin 1.0, spiritus 30.0; or resorcin 1.0, vanillin 1.0, spiritus 30.0).

Günzburg has prepared a table (see next page) to show the relative efficiency of these reagents and the uncertainties which various combinations may produce, and which are such as may occur in a sample of gastric juice or vomit.

The four reagents are fairly equal in delicacy in the detection of free HCl, the limits for two to three drops of the mixture examined being about one part of HCl in fifty thousand. The colors obtained vary a good deal in permanency, that from Boas's reagent, passing readily into the color due to combustion changes, which, according to Boas, may be avoided by very careful heating. The color from the resorcin-vanillin is nearly as transient, while that of indol-vanillin is the most permanent, and may even be extracted by alcohol.

Günzburg considers that the uncertainties caused by most of the inorganic compounds (1-3 of the table) have little clinical significance, and are probably caused by partial combustions. The red colors produced by the organic compounds (6-9) are admitted to be of importance, but are more misleading in testing with resorcin-vanillin or with Boas's reagent than with the others. The dangers from calcic chloride (1-5) he considers especially important, and believes that here free HCl is really formed.

The resorcin-vanillin test seems to him the least good of the four, and the indol-vanillin, because of

NUMBER.	REAGENT.	PHLOROGLUCIN-VANILLIN.	INDOL-VANILLIN.	RESORCIN-VANILLIN.	BOAS'S REAGENT.
	With HCl. Shows HCl in 1 c.cm. of a solution of :	Scarlet red. 1 : 90000.	Rose red. 1 : 90000.	Red violet. 1 : 80000.	Scarlet red. 1 : 80000.
1	NaCl.		Pale red.	On combustion slightly reddened.	Often reddened, but often colorless.
2	Sodium sulphate.	Green, or yellow brown, rarely red.	Green or vaguely red.	Red, sometimes violet or colorless.	Often colorless, but often reddened.
3	Sodium sulphate + acetic acid.	Yellow brown ; upon combustion, red.	Reddened.	Violet.	Often colorless, but often reddened.
4	Calcic chloride.	Fleeting pale red.	Rose red.	Traces of red.	No coloration.
5	Calcic chloride + acetic acid.	Strong rose red.	Red.	Red violet (feeble).	Transient reddening.
6	Sodic acetate.	Green, sometimes rose red.	Green.	Red violet (strong).	Scarlet red (strong).
7	Sod. acetate + lact. acid.	Rose red.	Green or transient red.	Red violet (strong).	Scarlet red.
8	Sodic lactate.	Red, yellow, red brown.	Green.	Red violet.	Red violet.
9	Sod. lact. + acetic acid.	Red to red brown.	Green.	Red violet.	Red violet.

odor and expense, only useful as a control-test. The phloroglucin-vanillin mixture, his own suggestion, still seems to him the best and most delicate, but he admits — and the admission is important in view of his earlier statements — that some organic acids, and especially calcic chloride, are sources of uncertainty ; but even here he believes that the uncertainties which arise when Boas's reagent is used are greater.

Boas also admits fully the difficulties met with in detecting small amounts of HCl by these reagents. He insists, however, that the difficulties are rather theoretical than real, and maintains that no case has been known where free hydrochloric acid was present (as shown by a digestion experiment), and yet any of these reagents failed to show it.

The positive result with these tests is valuable, and demonstrates fully the integrity of the secreting apparatus, while a negative result (as demonstrating the absence of free HCl) does not prove that the mucous membrane in question may not be functionally active.

#### ON THE TREATMENT OF LUPUS BY KOCH'S METHOD.

At the Session of the Imperial and Royal Society of Vienna, held January 16th, the subject of the treatment of lupus by Koch's method was under discussion.

Kaposi stated that he had thirty-two patients under treatment for about six weeks. He presented six of these at the meeting ; the improvement had been so great that they were regarded as cured ; the skin was everywhere smooth, and the seat of the lupus was free from tubercular nodules and ulceration. In most of these thirty-two patients, there was no local or general reaction after the third or fourth injection. In one patient who had a serpiginous lupus of the cheek, there was an intense reaction after the first injection ; after the twelfth injection of three centigrammes, the temperature remained normal, and there was no local reaction. In other cases, four, six and eight centigrammes were injected, but despite increase in the doses, there was no reaction.

It is known that the lupus centres first show themselves in the interstices of the chorion ; they are composed of a very vascular tissue in which are found giant cells with numerous nuclei, and always, according to Koch, a bacillus. But in reality tubercle bacilli are but rarely detected ; not more than once in thirty or forty sections, according to Kaposi. Koch says that the bacilli have the special property of necrosing the surrounding tissues by the products which they secrete. If, then, we inject these products, we introduce into the circulation an element which augments the necrosing action ; we, in fact, produce a destructive inflammation fatal to the tuberculous process. At the end of a certain time, the extract produced by the bacilli no longer acts in small doses, and to obtain any effect, it is necessary to increase the dose ; and as the normal protoplasm is attacked by Koch's liquid, there must result a certain damage to the organism.

In some cases, Kaposi has derived benefit from an interruption of the injections for two or three weeks ; then they are begun again in small doses, on the supposition that the bacilli have acquired a new vitality.

Kaposi has not much faith in the ultimate and permanent success of the injections. It must be remembered, that according to Billroth, the bacilli have an irritative or rather formative action ; the lupus will be for the time arrested by the injections, then, as the bacilli remain in the tissues, it will break out again ; new foci will form. We turn, says Kaposi, in a vicious circle. On the one hand, we exercise a favorable action on the lupus by means of the injections ; on the other, the interruptions enable the lupus to continue its development, and as the bacilli cannot be evicted from their haunts, they may penetrate the lymphatics, and provoke metastases. He presented to the Society a patient who had been ameliorated by the treatment, then had presented new lupoid lesions. The problem to solve, then, is to promote elimination in some other way. The thermocautery and the cutting curette will remain indispensable in the future.

At the same meeting Billroth made mention of two cases which exactly confirmed the conclusions of

Kaposi. One of these patients was sent to his surgical clinic for a rhinoplasty; he was thought to be cured, but the upper lip was still hard and infiltrated. This infiltration disappeared after several injections. An interruption of twelve days was made; then a moderate dose was injected, and the reaction was extremely severe. Afterwards, the injections were continued up to fifteen centigrammes, and all reaction ceased. In another case of lupus, there was a very violent reaction; during an interruption of a fortnight the lupoid lesions underwent a new development. This young man, aged sixteen years, had, after an injection of five milligrammes, a scarlatiniform eruption, a temperature of 41° C., and hæmaturia. In a child affected with multiple external tubercular lesions, an injection of a centigramme and a half produced no reaction at all.

#### ANNUAL REPORT OF THE NEW YORK STATE BOARD OF HEALTH.

THE report of the New York State Board of Health, containing the bulletin for the month of December, and a summary of the mortality of the State for the year 1890, shows that the total reported mortality for December was about 1,000 greater than for November, in which month the number of deaths is invariably smaller than in any other month during the year. The mortality from zymotic diseases, however, was but little greater than in November; the increase being mainly from diseases of the respiratory organs. There were 500 more deaths from acute respiratory diseases, and the number was greater than in December, 1889, notwithstanding the fact that the *grippe* epidemic commenced in that month.

The summary for the year 1890 gives the number of deaths occurring in the State as 127,630, or, estimating the population at 6,000,000, at the rate of 19.6 deaths per 1,000 inhabitants.

One noteworthy fact is that in the maritime district of the State, including New York City, Brooklyn, and the rest of Long Island, Staten Island, and Westchester County, the death-rate from typhoid fever, is much smaller than in any other portion of the State. Out of every 1,000 deaths in this maritime district, but 9.26 are from typhoid fever; the Adirondack and northern district coming with the next smallest percentage, of 13.33 deaths per 1,000. From phthisis, on the other hand, there were 127.72 deaths out of every thousand in the maritime district, while the rate in the entire State was 118.37 per thousand deaths.

The zymotic diseases taken together show a mortality of 169 per each thousand deaths; which is less than has been the case for the last five years. Scarlet fever caused scarcely one-third the number of deaths that it did in the two preceding years, while the mortality from measles was actually greater than that from scarlet fever, and greater than in either 1888 or 1889. The mortality from chronic phthisis was less than in 1889, but the effect of the *grippe* was seen in

the large increase of deaths from acute respiratory diseases, which were largely in excess of those of the previous years.

#### THE STATUS OF HYGIENE IN GERMANY.

In the latest number of the *Centralblatt für Allgemeine Gesundheitspflege* (X.1.), a list is given of the professorships of Hygiene in the German Universities, with the names of the several professors. The number and quality of these is highly significant of the progress which the so-called "preventive medicine" has already made in Germany.

They are as follows: Koch, in Berlin; Finkelnburg, in Bonn; Flüge, in Breslau; Wolffhügel, in Göttingen; Löffler, in Greifswald; Reuk, in Halle; Bockendahl and Fischer, in Kiel; Fraenkel, in Königsberg; Rubner, in Marburg; Schottelius, in Freiburg; Knauff, in Heidelberg; Rosenthal, in Erlangen; v. Pettenkofer, in Munich; Lehmann, in Würzburg; Gaffky, in Giessen; Uffelmann, in Rostock; Hoffmann, in Leipzig; Gärtner, in Jena. Tubingen and Strassburg appear to be the only German Universities which have no special professors of Hygiene.

It would be difficult to bring forward any better evidence of the superiority of Germany in respect to scientific medical education than this list affords. A similar list of English or American foundations of this kind would be instructive though humiliating.

#### MEDICAL NOTES.

STATE CONTROL OF KOCHINE.—It is reported that, although the German government has definitely abandoned the monopoly of the production of Kochine, measures are being prepared for a rigid State control of its sale, and a strict supervision of its manufacture. Chemists will not be allowed to sell it unless the State analysts have confirmed its purity.

THE FIRST KOCH INSTITUTE.—We learn from the *New York Medical Journal* that Dr. Alex. J. Aronson has opened, at 196 East Broadway, New York, an institution for the treatment of tuberculous diseases by the Koch method. A prominent medical authority has been secured as consulting physician. Patients are inoculated in the order of their admission. Those who desire private accommodations can obtain them. Letters from attending physicians are required.

SUICIDES OF SCHOOL CHILDREN IN GERMANY.—During the last eight years 289 school children committed suicide in Germany; of these, 49 were girls. The causes assigned were, fear of punishment, 80; mental disease, 26; morbid ambition, 19; fear of examination, 16; practical joking, 7; disappointed love, 5. This is a terrible indictment against "over-pressure," the effects of which can scarcely be expected to be limited to those hapless children who are driven to destroy themselves.

SOME RECENT DECISIONS are briefly summarized by Henry A. Riley, Esq. in the *Medical Record*, as

follows: In Georgia the sorrow of a woman over her miscarriage is not a ground for damages. In Tennessee a man cannot be punished for taking part in a duel on Arkansas soil. In Kansas, cemeteries do not last forever, but can be abandoned and the land used for other purposes. In California the Legislature can properly direct that the scholars in the public schools shall be vaccinated. A Maryland court has declared that no plumber shall practise his profession in Baltimore without a certificate from the Commissioners of Practical Plumbing. In Massachusetts it is not proper for a Catholic priest to forbid the members of his church to employ a certain physician. In Indiana mental anguish is a good ground for a verdict for damages for neglect in delivering a telegram. In Kentucky oral evidence of a dying declaration can be given when a written statement made by the injured man has been destroyed by the accused. In North Carolina a woman who has had sexual intercourse with a man, but has long since repented, is an "innocent" woman in the eye of the law. In Illinois a very young child straying into a dangerous place and getting injured can recover damages, the negligence of the parents not being imputed to it.

**FIGHTING THE FROST IN FRANCE.**—The action of the French Government and the Paris Municipality in dealing with the exceptional distress caused by the prolonged winter, is praiseworthy. The Chambers and the Senate voted over a million dollars, and decided to dispense with all administrative formalities, so that the money reached the poor and the suffering in about twenty-four hours. The Government issued orders that persons imprisoned for vagrancy might remain in prison till the frost ceases if they so desire; and it is a proof of the severity of the distress that no less than seven hundred vagrants took advantage of the offer. What remains of the great Exhibition of 1889 was converted into a refuge for the destitute. The Fine Art Galleries are converted into vast dormitories. More than six thousand mattresses and rugs were provided by the Minister of War, so that plenty of good beds were prepared in a very few hours. In the streets large braziers were burning day and night so that pedestrians might warm themselves.

**SOCIALISM IN MEDICINE.**—The late Socialist Congress held at Halle, Germany, added a most unique and far-reaching proposition to its platform. This was the suggestion that the functions of the Sanitary Department of the Government be extended so as to embrace all the members of the medical profession, and to make them public functionaries. The report of a debate on the above proposition at the Labor Lyceum in New Haven, reminds one of Bolshak's "Looking Backward." The proposals suggested are roughly outlined, as follows: "The present Board of Health to be authorized by the proper authorities to enlist all the doctors of New Haven as members of the Board of Health; To divide the city into sanitary districts connected by a system of telegraph and telephone lines with the headquarters of the Board; To

doctors to be divided into suitable classes of specialists, for the purpose of having a complete representation of medical science at headquarters, each doctor to serve a regular term of duty, six hours a day at headquarters; The Board to establish a sanitary patrol covering the entire city; The Board, as a committee of the whole, to fix the salaries of its members, choose its own officers, etc.; The citizens to have the right to summon, free of charge, any medical aid from the Board of Health, such aid to be sent immediately, and if upon examination a specialist of any class be desirable or necessary, such specialist to be sent at once from headquarters; medicine to be also furnished free of charge to any citizen if ordered by a physician; The cost of maintaining this institution to be raised by a direct tax, the same as the school tax."

#### BOSTON AND NEW ENGLAND.

**LEGISLATIVE HEARING ON THE SPREAD OF CONTAGIOUS DISEASES.**—The Committee on Public Health of the Massachusetts Legislature gave a hearing on February 9th to those interested in the subject of the legislative control of "malignant contagious diseases." The proposed bill is as follows: "*Be it enacted, etc.*: That any inmate of any criminal or State charitable institution, who has syphilis, shall at once be placed under medical observation and treatment, and shall not be discharged therefrom until three months after all infectious symptoms have disappeared. This Act shall not be construed to apply to any institution supported by private charity." Drs. C. Irving Fisher, J. C. White and F. B. Greenough, the committee appointed by the Suffolk District of the Massachusetts Medical Society, Section for Clinical Medicine, Pathology and Hygiene on May 21, 1890, appeared at the hearing, as did also Dr. A. Johnson, President of the Massachusetts Medical Society, Dr. S. W. Abbott, of the State Board of Health, and Dr. J. H. McCollum, Boston City Physician.

**ON EMBALMING.**—The house judiciary committee of the Massachusetts Legislature recently gave a hearing upon the order as to providing that no body shall be embalmed nor any embalming fluid be used on the body until a physician's certificate of the cause of death be obtained. Dr. F. W. Draper, medical examiner of Suffolk County, appeared in behalf of the order, and stated that under the present system it was often very difficult, and even impossible, for physicians to discover the causes of sudden deaths when once the embalming fluid had been used upon the body. Dr. F. A. Harris, medical examiner for the same county, said that the post-mortem condition and appearance of the body was almost entirely changed by the application of the embalming fluid. Dr. T. M. Durrell stated that in cases of poisoning this embalming process rendered it impossible to prove that poison had really been used, and that what was wanted was a few hours' delay, in order that the causes of sudden death might be made known. He was in favor of a ten hour limit. Mr. H. G. Allen, in behalf of the un-

dertakers of the State, appeared in opposition to the measure. He maintained that some process of preservation should be used in cases of sudden death.

**MEDICAL INSPECTOR AT QUARANTINE.**—Quarantine regulations for the port of Boston have hitherto been under the direction of the Board of Health, but Collector Beard has been informed by the Treasury Department that Passed Assistant Surgeon W. J. Pettus of the United States Marine Hospital Service has been detailed to perform duty as medical officer for the inspection of immigrants and vessels coming from foreign ports. Surgeon Pettus has been regularly engaged on medical duty at the Marine Hospital, Chelsea.

**HOSPITAL PHYSICIANS' RESIGNATIONS ACCEPTED.**—The executive committee of the Newton, Mass., Cottage Hospital have accepted the resignations of the members of the medical board of the hospital. The executive committee wish it distinctly understood that the resignations are accepted in the same friendly spirit in which they are tendered.

**POISONED BY ALCOHOLENE.**—It is reported that a large can of this preparation was recently delivered by express at the reformatory at Concord, Mass., and a young man, watching his opportunity, poured some of the liquid from the can into a smaller vessel and secreted it. He managed in some way to get the quantity he had smuggled to four of his companions, who all partook of it. As a consequence two of the men have died, and the others are in the hospital.

#### NEW YORK.

**THE ANNUAL REPORT OF THE ST. JOHN'S GUILD** shows that during the summer of 1890, 26,135 sick children and mothers were taken on the trips of the floating hospital belonging to the institution, and 1,343 were cared for at the Seaside Hospital at New Dorp, Staten Island. During the twenty-four seasons that the floating hospital has been in use it has carried 126,393 mothers and children on its trips.

**ANNUAL REPORT OF THE HOSPITAL BOOK AND NEWSPAPER SOCIETY.**—The sixteenth annual report of this Society, the work of which is to distribute reading matter to hospital patients shows that during the year it supplied to fifty-nine public institutions, 1,910 books, 14,870 magazines, 39,811 weekly papers, and 131,993 daily papers.

**LECTURES TO MOTHERS AND NURSES.**—A free course of weekly practical lectures to mothers and nurses has been begun at the New York Post-Graduate Medical School and Hospital. Among the subjects and lecturers are the following: "The Care of the Eye," by Dr. D. B. St. John Roosa; "The Most Frequent Surgical Incidents of Infancy and Early Childhood," by Dr. Robert Abbe; "The Care of the Skin in Health and Disease," by Dr. L. D. Bulkley; "Practical Points in the Nursing at the Babies' Wards as Employed in Lung Diseases, Fevers, Intestinal Diseases," etc., by Dr. Henry D. Chapin; "Infant Feeding and the General Care of Young Children," by Dr. J. H. Ripley.

## Miscellany.

### HARVARD MEDICAL SCHOOL ASSOCIATION.

A MEETING was held in Boston on November 26, 1890, with Dr. A. H. Johnson, President of the Massachusetts Medical Society, in the chair, to consider the advisability of forming a Harvard Medical School Association. After full discussion, it was unanimously voted expedient to do so, and Drs. James R. Chadwick, Francis H. Brown, H. P. Bowditch, George E. Francis, and Lincoln R. Stone, were appointed a committee to draft a constitution, to invite all graduates of the school to enroll themselves, and to call a meeting for permanent organization as soon as is deemed expedient. The plan is to have a meeting and dinner at least once a year. The committee, after carefully estimating the probable expenses, have voted to recommend an initiation fee of one dollar and an annual assessment of one dollar.

Attention is directed to the success of the Harvard Law School Association, and to the benefits to its members, as well as to the University, brought about by its existence. It is thought that the mere catalogue of the members of a similar Medical School Association will be of great value in enabling physicians to ascertain what graduates of the Harvard Medical School are resident in the various cities of the Union, and in thus guiding their choice of physicians to be consulted by patients travelling in distant parts of the country.

Graduates of the Harvard Medical School are invited to signify to the Chairman, Dr. James R. Chadwick, 270 Clarendon Street, Boston, at an early date, their willingness to become members of the Association.

### CHLOROSIS AND ITS TREATMENT.<sup>1</sup>

DR. FREDERICK SCHOLZ of Bremen, has published a remarkable work on chlorosis, the outcome of observations made during the last twenty years. Instead of regarding the deficiency of iron or hæmoglobin, or even that of the red corpuscles, as the primary affection, he states that contraction of the vessels is always present in these cases, as indeed was observed by Bamberger, Rokitansky, and Virchow; and this, he contends, is not to be regarded as a complication due to an altered condition of the blood, but as the primary condition which is followed by the morbid change in the blood. As a matter of fact, the vessels are, he says, too full, or in the condition termed by the older physicians "plethora ad vasa," the blood being—or becoming—abnormally serous. Long ago his attention was struck by the cold and livid condition of the skin in anæmic subjects, and he was led by this to employ hot baths, together with gentle friction, in the treatment, with the view of acting directly upon the skin, so as to improve the vitality and nutrition generally. The success of his first attempts was so marked that he was encouraged to persevere in this line of treatment, and he has since had many opportunities of extending his experience with it. Hot baths diminish the plethora by relaxing the tension of the vascular system, which is high, quickening the circulation, and thus relieving the palpitation, dyspnoea, and other symptoms. In thirty cases where the distress of the

<sup>1</sup>The Lancet, January 24th.

patient was very great, Dr. Scholz has gone a step further and supplemented the hot bath by venesection. Paradoxical as this treatment may appear, it was followed by marked benefit, and if the theory of the pathology of chlorosis above mentioned be correct, there can be little doubt that the novel line of treatment practised by Dr. Scholz is justifiable.

### ALPHA AND BETA NAPHTHOL.

THE *Lyon Médical*<sup>1</sup> recently reviewed the history of alpha and beta naphthols that are obtained by the substitution of hydroxyl for an atom of hydrogen in naphthalene. Alpha naphthol crystallizes in white, brilliant needles or prisms; beta naphthol forms colorless or roseate, silky, crystalline plates. Each is odorless, very soluble in alcohol, in ether, in benzine and in chloroform, less soluble in glycerin, and but very slightly soluble in water. Beta naphthol was the first that was employed in medicine, being used in the treatment of skin diseases. Dr. Bouchard thought that the drug could be employed internally with advantage in diseases in which intestinal antiseptics was necessary, because a 1250 solution inhibited the growth of micro-organisms and prevented the fermentation of urine to which it was added. It is not toxic in doses of about a drachm to the kilogramme of weight of an animal, and thirty-nine grains are sufficient to produce intestinal antiseptics. Dr. Maximowitch alleges for alpha naphthol an antiseptic value superior to that of beta naphthol, and says that at the same time it is far less toxic. Internally they may be administered in powder, in doses of from thirty to forty grains a day, or dissolved in oil of sweet almonds. Externally they may be used in an ointment, and, in alcoholic solution, for urethral, vaginal, or nasal injections.

### TROPHIC CHANGES IN THE NAILS IN MULTIPLE NEURITIS.

BIELSCHOWSKY<sup>2</sup> describes a man, aged forty, who presented the symptoms of peripheral neuritis. In the course of the illness several white spots appeared at the lower part of the finger nails. They rapidly grew, and in two or three weeks there were milk-white patches stretching across the nail. There were no similar changes in the nails of the toes. Except for these alterations, there were no other changes in the nails. There was not the loss of smoothness which has been described. The streaks across the nail remained milk white in the middle, but became reddish towards the ends. The borders of the depressed streaks were straight. When these streaks had grown near enough to the end of the nail, they were cut off. The microscopical examination seemed to show that the discoloration was due to the presence of air, and that the condition was thus similar to what is found in hair which has become gray or white.

### PRESCRIPTIONS.

PALATABLE CASTOR-OIL MIXTURE.<sup>3</sup>—In the following preparation of castor-oil the disagreeable taste of the oil is replaced by a pleasant flavor of almonds:

The only drawback to this mixture is that it requires a good deal of it for a dose, a teaspoonful of the oil being contained in about five teaspoonfuls of the mixture.

R	Castor oil	. . . . .	30 parts.
	Bitter almonds	. . . . .	2 parts.
	Sugar	. . . . .	30 parts.
	Gum tragacanth	. . . . .	1 part.
	Orange-flower water	. . . . .	10 parts.
	Water	. . . . .	120 parts. M.

ECZEMA OF THE NOSTRILS. — Kaposi<sup>4</sup> recommends the following treatment:

R	Sodii chloridi	}	. . . . . 3 j.
	Sodii bicarbonatis		
	Sodii boratis		
	Acidi salicylici		
			M.

A large pinch of this powder is dissolved in a glass of lukewarm water, and used as a wash. During the night pieces of cotton wool with oxide of zinc salve are inserted.

## Correspondence.

### WARREN TRIENNIAL PRIZE.

MASSACHUSETTS GENERAL HOSPITAL.  
BOSTON, January 1, 1891.

MR. EDITOR:—The Warren Triennial Prize was founded by the late Dr. J. Mason Warren in memory of his father, and his will provides that the accumulated interest of the fund shall be awarded every three years to the best dissertation, considered worthy of a premium, on some subject in Physiology, Surgery or Pathological Anatomy; the arbitrators being the physicians and surgeons of the Massachusetts General Hospital.

The subject for competition for the year 1892 is on some special subject in Physiology, Surgery or Pathology.

Dissertations must be legibly written, and must be suitably bound so as to be easily handled. The name of the writer must be enclosed in a sealed envelope, on which must be written a motto corresponding with one on the accompanying dissertation.

Any clue given by the dissertation, or any action on the part of the writer which reveals his name before the award of the prize, will disqualify him from receiving the same.

The amount of the prize for the year 1892 will be \$500. In case no dissertation is considered sufficiently meritorious, no award will be made.

A high value will be placed on original work.

Respectfully yours,

J. W. PRATT, Resident Physician.

\* Union Médicale.

### METEOROLOGICAL RECORD,

For the week ending Jan. 31, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Deaths reported, 2,871: under five years of age 1,018; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 400, acute lung diseases 487, consumption 350, diphtheria and croup 177, scarlet fever 56, typhoid fever 48, measles 48, diarrhoeal diseases 239, whooping-cough 24, erysipelas 18, cerebro-spinal meningitis 13, malarial fever 6.

From measles New York 32, Chicago 9, Brooklyn 5, Boston and Washington 1 each. From diarrhoeal diseases New York 11, St. Louis 6, Chicago 3, Boston, Washington and Lawrence 3 each, Brooklyn, Cincinnati and Lowell 2 each, Nashville and Worcester 1 each. From whooping-cough New York 11, Brooklyn 6, Chicago 2, St. Louis, Boston, Cincinnati, Springfield and New Bedford 1 each. From erysipelas New York 7, Washington 3, Chicago, Philadelphia and Boston 2 each, Brooklyn and St. Louis 1 each. From cerebro-spinal meningitis New York, Chicago and Washington 3 each, Philadelphia, Brooklyn, Boston and Lynn 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 10,010,426, for the week ending January 17th, the death-rate was 27.3. Deaths reported 5,340: acute diseases of the respiratory organs (London) 1,918, measles 141, whooping-cough 115, scarlet fever 51, diphtheria 35, fever 32, diarrhoea 29.

The death-rates ranged from 11.9 in Hull to 35.2 in Halifax, Birmingham 25.8, Bradford 19.9, Leeds 28.6, Leicester 24.4, Liverpool 25.5, London 29.2, Manchester 35.0, Nottingham 19.0, Sheffield 21.0, Sunderland 22.2.

In Edinburgh 20.6, Glasgow 35.7, Dublin 37.1.

## OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 31, 1891, TO FEBRUARY 6, 1891.

By direction of the Secretary of War, Captain WILLIAM S. PATOZKI, assistant surgeon, will proceed, without delay, from Columbus Barracks, 42, to Fort Wayne, Mich., and report in person to the commanding officer of that post for temporary duty, and, upon the completion thereof, will return to his proper station. S. O. 23, Par. 13, A. G. O., Washington, D. C., January 28, 1891.

By direction of the Secretary of War, leave of absence for six months, with permission to go beyond sea, is granted Major

JULIUS H. PATOZKI, surgeon. S. O. 24, Par. 5, A. G. O., Washington, D. C., January 29, 1891.

Leave of absence for one month, with permission to apply to the Adjutant-General of the Army for an extension of one month, is granted Captain ALONZO R. CHAPIN, assistant surgeon, Fort Yates, N. D. S. O. 17, Par. 3, Department Dakota, St. Paul, Minn., January 31, 1891.

By direction of the Secretary of War, Major CALVIN DEWITT, surgeon, is relieved from duty at Fort Hancock, Tex., and will report in person to the commanding officer, Fort Sam Houston, Tex., for duty at that station. S. O. 27, Par. 1, A. G. O., Washington, D. C., February 3, 1891.

## OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING FEBRUARY 7, 1891.

SAWTELLE, H. W., surgeon. Detailed as member of Board, Revenue Marine Service. January 26, 1891.

AUSTIN, H. W., surgeon. Detailed as Chairman of Boards for physical examination of Officers of Revenue Marine Service. January 28 and February 6, 1891.

PETTUS, W. A., passed assistant surgeon. Detailed as Medical Inspector of Immigrants, Port of Boston, Mass. January 29, 1891.

MAGRUDER, G. M., passed assistant surgeon. Detailed as Recorder of Boards for physical examination of Officers of Revenue Marine Service. January 28 and February 6, 1891.

KINYOUN, J. J., passed assistant surgeon. Detailed for special duty at Berlin, Germany. January 26, 1891.

GROENEVELT, J. F., assistant surgeon. To proceed to Cape Charles Quarantine for temporary duty. February 7, 1891.

## AN ARMY MEDICAL BOARD.

An Army Medical Board will be in session in New York City, N. Y., during April, 1891, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before April 1, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character and moral habits. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a regular medical college, as evidence of which, his diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon General U. S. Army, Washington, D. C.

C. SUTHERLAND, Surgeon General U. S. Army.

## DEATHS.

James R. Cummings, M.D., of Bridgeport, Conn., died, February 4th, aged sixty-nine. He was born in Winsted, Conn., and graduated from Columbia College. During the war he was surgeon of the Fourteenth Connecticut Regiment.

S. S. Strong, M.D., of Saratoga, N. Y., died, February 1st, aged seventy-eight.

W. Orlando Markham, M.D., F.R.C.P., formerly editor of the *British Medical Journal*, Goulstonian lecturer, etc., died January 23d, aged seventy-two.

Edward John Waring, M.D., F.R.C.P., etc., surgeon-major, retired, widely known as a therapeutist, died in London, January 23d, aged seventy-one. He had spent most of his professional life in India.

## BOOKS AND PAMPHLETS RECEIVED.

Sixteenth Report of the Salem Hospital. 1891.

The Parasitic Nature of Psoriasis; Its Treatment by Mercury. By E. D. Mapother, M.D., F.R.C.S.I. Reprint. 1891.

Mechanical Obstruction in Diseases of the Uterus. By George F. Hulbert, M.D., of St. Louis, Mo. Reprint. 1890.

Souvenirs de l'Exposition de 1889. Extraits d'un Rapport Adresse a la Société Bibliographique Française et Étrangère.

Biennial Message of Joseph W. Fifer, Governor of Illinois, to the Thirty-seventh General Assembly, Springfield, Ill. 1891.

## Address.

### EARLY DIAGNOSIS OF SOME SERIOUS DISEASES OF THE NERVOUS SYSTEM; ITS IMPORTANCE AND FEASIBILITY.<sup>1</sup>

BY E. C. SEGUIN, M.D., PROVIDENCE, R. I.

#### IV. VERTEBRAL DISEASE (CARIES, ETC.).

It may seem strange that I should call your attention to conditions which apparently belong to quite a different specialty from neurology; but, gentlemen, the first and the last symptoms of these diseases (spondylitis, caries of the spine, vertebral cancer) are nervous symptoms. The case appears at first as one of rebellious neuralgia or muscular rheumatism, and lastly as one of paraplegia. The early symptoms do not very distinctly point to the vertebrae as the site of disease; and thus usually the cases remain a long time — during the best time for successful treatment — in the hands of the general practitioner; then, later, they are passed on to the neurologist or orthopedist.

Many precious months are thus lost. Yet, if the few symptoms present during the first stage of these diseases are rightly appreciated and correctly interpreted, I believe a diagnosis should always be possible long before angular curvature (representing the breaking-down of one or several vertebrae) or tumor appears. The early symptoms of spondylitis or tumor are the same in kind, no matter what part of the spine is affected, but their distribution varies according to the location of the lesion up or down in the vertebral column. This distribution is so peculiar as to enable us to feel with almost absolute certainty which vertebrae are affected.

The capital symptoms of the first stage of Pott's disease or of vertebral cancer are only two in number, namely: (a) a fixed pain seemingly of a neuralgic character, far away from the spine. (b) Rigidity of certain muscles attached to the spinal column; a reflex protective or conservative spasm. The distant pain is increased by attempts to overcome the muscular spasm, and by jars.

It will be necessary to consider these symptoms as distributed when the disease (caries, tubercle or cancer of the vertebrae) attacks different regions of the spinal column.

(a) The "neuralgic" pains, and spasm.

(1) Disease of the uppermost cervical vertebrae, spondylitis colli, is not rare. The patient complains in the first place, and chiefly of pain in one occipital region, aggravated by motion or jar. On analysis, we find the pain to follow the range of distribution of the greater and lesser occipital nerves; one or both. Occasionally there is also pain in the temple of the same side. Almost invariably this neuralgic pain for which the patient asks relief, is unilateral.

Inspection reveals at quite an early period a slight or decided "wry-neck," a deviation of the head from its proper vertical position. It is a peculiar oblique attitude, dissimilar from that produced by (functional) spasm of one sterno-mastoid. Any attempt to correct this deviation, and indeed any passive movement of the head and neck cause greatly increased pain in the occipital region (not in the spine). Sudden pressure on the top of the head by the physician's hand causes

excruciating pain of similar distribution. The spine itself is not tender or deformed. The patient tells you that the jar of a carriage or horse-car, or of a false step causes intense agony. Some patients very early acquire an instinctive habit of supporting or steadying their heads with their hands, to avoid effects of shock. Further examination shows that the deeper cervical muscles, extensors, flexors and rotators are in a state of constant spasm, more especially on the side of the pain.

Let us see if anatomy helps us in diagnosis. The occipitalis major nerve is mainly a branch of the second cervical nerve; the minor, of the first cervical nerve. They, however, have branches of intercommunication. Most filaments of these nerves are sensory, supplying the scalp of the occiput and parietal regions. Motor fibres from these two cervical nerves supply the small, deep muscles which govern the movements of the skull upon the vertebral column.

Consequently, both the "neuralgia" and the spasm point infallibly to disease in or about the two upper vertebrae. The exact nature of the lesion may be in doubt, but we have by strictly scientific methods located the disease; it is so placed as to irritate the first and second cervical nerves.

(2) Disease of the lower cervical vertebrae is very rare. In such a case the pain would be in the lower part of the neck, or in one arm or hand according to the exact location of the lesion. The spasm would be in the lower cervical muscles and in those of the arm.

(3) The most common location of these lesions is in the dorsal region, between the fifth and the twelfth dorsal vertebrae. Many and many a child is treated for months for "colic" because he complains of a pain in one side of the abdomen. The too frequent neglect of thorough objective examination here leads to the erroneous diagnosis of intercostal or abdominal neuralgia, or of colic; even of "hepatalgia," according to the exact seat of pain. The muscular symptoms are present here also, but not in as striking a shape as in spondylitis colli. They must be sought for by careful examination. This reveals one of several conditions or several combined. The respiratory thoracic or abdominal movements on one side (rarely on both) are hindered, and the muscles appear to palpation hard or rigid. The various movements of the spinal column are not normally free. Turning the head about as if to look for something is done by a turning of the whole body, flexion and extension (latero-flexion more especially) of the spine are checked by pain or directly hindered by rigidity of the erector spinae muscles. A segment of the dorsal spinal column is rigid during all attempts at movement. The tenderness of the dorsal nerves cannot be demonstrated by direct testing with finger pressure, but it is strikingly revealed by what I call the heel-jar test. This consists in placing the patient standing in the military position of "attention," on a hard floor. Then tell him to rise on his toes and then suddenly to drop his whole weight on his heels. If there is vertebral disease, decided or excruciating pain is caused by this jar, not in the spine but in the location of the "neuralgia" for which the patient consults you. This heel-jar test is useful in any location of the vertebral disease. The origin of the nerve which is the seat of pain, the range of the muscular rigidity will enable us to localize the lesion to the exact vertebra or vertebrae.

<sup>1</sup> Delivered before the Providence Medical Association, December 1, 1890. Continued from page 132 of the Journal.

(4) The lumbar vertebrae are sometimes diseased. In such a case the pain would be in the groin and anterior and inner parts of thigh; the spasm in the same parts; especially in the psoæ and iliac muscles.

(5) Caries of the sacrum gives rise to pains in the perineum, posterior part of thigh; and in the leg and foot. Cramps or spasms would occur in the same parts (seldom present).

The general diagnostic law may be formulated as follows: The seat of neuralgia and of spasm, though occasionally not in corresponding parts,<sup>15</sup> clearly refer to irritation (compression) of one or more spinal nerves on one side. A knowledge of the distribution of spinal nerves enables us to state with great accuracy which vertebrae are diseased.<sup>16</sup>

(b) With reference to paralytic symptoms.

Occasionally they appear before actual destruction of bone brings about angular curvature; the spinal cord being compressed by inflammatory or caseous masses originating in pachymeningitis; or by a tumor. When the disease affects the two upper cervical vertebrae, the paralysis may be hemiplegic, face not affected. This is because the caseous masses have formed on one side of the canal and exerted pressure on one side of the spinal cord, where the large crossed pyramidal fasciculi run downward; hence hemiplegia. Below the level of the second vertebra the masses which compress the cord are formed anteriorly as a rule, and cause pressure almost equally on both sides of the median line; hence paraplegia; of the type "cervical paraplegia," where the whole body below the neck is paralyzed, or "common paraplegia," when the lower limbs and a varying extent of the trunk are paralyzed. It is important to determine the uppermost limit-line of the paralysis, as this usually indicates the limit of intra-vertebral lesion.

When caries exists in the mid-dorsal region, vesical paralysis (retention) is, in my experience, a very early symptom; sometimes existing without other paralysis. With disease of the upper cervical vertebrae we also observe paralysis of the small, deep muscles connecting the head with the spine ("loose head").

When the lumbar vertebrae below the second, or the sacrum is the seat of caries (or cancer), a very peculiar paralysis results. As there is no spinal cord below the level of the first lumbar vertebra, pressure below this point will affect only nerve-bundles; the constituents of the *cauda equina*.

Physiologically, therefore, the resultant paralysis is a peripheral or neural paralysis (precisely the same as when an outside nerve-trunk is injured), characterized by a flaccid atrophic paralysis, with degenerative reactions; co-extensive anesthesia; absence of all reflexes; relaxation of the sphincter ani and vesical paralysis. The paralysis is nearly all below the knees, assume of the thigh-muscles are supplied by the crural plexus.<sup>17</sup>

We can thus—I hope to have made it clear and easily understood—readily make a diagnosis of a ver-

tebral bony lesion or of an intra-spinal tumor at a very early period; months before angular curvature (kyphosis) or external tumor shows itself. In my opinion there is no justification for waiting till kyphosis appears before reaching a diagnosis. The exact seat of the lesion we can, also, by the help of anatomy, always determine with accuracy.

The further diagnosis, namely, that of the nature of the vertebral lesion, is a most interesting, but complicated problem, which I cannot enter upon to-night. The neural irritation or spinal-cord compression, may be due to pachymeningitis, to vertebral caries (spondylitis), to peri-vertebral or intra-vertebral tumors, or to cancer of the bodies of the vertebrae themselves.

Let it suffice, if I have made it clear, that occipital neuralgia, with rigid, painful wry-neck; intercostal or abdominal local pains (neuralgia so-called), one-sided pains along some nerve of the lower extremities; with associated spasm, mean, or at least suggest, vertebral disease of some sort, and call for a careful objective examination, instead of an off-hand prescription, for the symptom complained of.

#### V. EPILEPSY.

It is perhaps more important to make an early diagnosis of this protean affection than of any of those previously studied, because there is no doubt but that by early, careful, and long-continued treatment it can be, in a small minority of cases, cured. What this proportion is no one can tell. In my own experience I have records of several cases which have been perfectly free from attacks (from any manifestation of epilepsy), for upward of four years; yet I am hardly prepared to report them as cures. Recently, one of my cases relapsed after an interval of over ten years, but as I have only the patient's bare statement, and she lives far away: there is just a possibility that the attack was hysterical. Still, I do believe that some cases are cured.

Epilepsy is a chronic disease characterized by the recurrence, at irregular intervals, of attacks, (seizures or popularly speaking "spells" or "fits"). These attacks vary extremely in form; some are terrific in their violence, others so slight and transient as to escape the observation of even experienced physicians. The various forms may, however, be classified with sufficient accuracy under the five following types or varieties.

(1) Simple motor epilepsy (epileptiform spasms without loss of consciousness): Jacksonian epilepsy. These spasms are localized in various parts of the body. Sooner or later loss of consciousness follows the spasms, thus demonstrating its relationship with:

(2) Common spasmodic epilepsy (*grand-mal*).

(3) Attacks, with slight momentary tonic spasm, or consisting only (?) of a peculiar momentary sensation in the head. In both these is a short loss of consciousness, though the patient frequently denies it. This is sometimes called epileptic vertigo (a misuse of the word vertigo) or *petit mal*.

(4) Psychical epilepsy; in which a seemingly volitional co-ordinated action (often complex) constitutes the seizure; or it may appear as a temporary insane condition or psychosis.

(5) Hystero-epilepsy; a hybrid form in which symptoms of epilepsy and of motor hysteria are variously combined.

These types may co-exist in one individual, any two

<sup>15</sup> The parts which are the seat of neuralgia and spasm do not always correspond in a topographical sense, but they always do form a physiological sense in accordance to Van der Kolk's law, namely, that the sensory branches of a mixed nerve trunk (or of a plexus) supply the skin of the part which is moved by muscles which receive its motor filaments. This law finds a wide application in neurologized diagnosis.

<sup>16</sup> Consult the diagrams and schemes of spinal nerve distribution in several of my text-books on neurology.

<sup>17</sup> If the previous symptoms—neuralgic pains and muscular spasm be ignored, there is some danger of confounding the case with one of sub-acute or chronic polyneuritis; though in this disease anesthesia and sensorial paralysis do not occur.

or all of them. Careful inquiry reveals the occurrence of *petit-mal* in many cases of *grand-mal*.

However varied may be the combinations of types of attack, the successive seizures of each type almost exactly resemble each other in a given patient. We say that epileptic attacks are, as it were, stereotyped. Careful attention to this point will help in its diagnosis from hysteria and malingering. For example, if a patient have at different times attacks of *grand-mal*, of *petit-mal*, and of psychic epilepsy, the succeeding seizures of each type will be almost absolute copies of the preceding ones of that type. As we sometimes say of the heart's action, there is a regular irregularity in the symptoms.

Some authorities reject simple motor spasm from the class of epileptic manifestations, but any one who has watched the evolution of a case of symptomatic epilepsy (from a cerebral tumor for example), will be convinced that the loss of consciousness, clonic movements and asphyxial stage, are but the crowning feature of an extension, topographically and in severity, of the spasm which at first was very local, for example, in one hand and forearm; or, in other cases, simple motor seizures alternate with typical attacks of *grand-mal*. The proof of the epileptic nature of psychic seizures is also obtained by our knowledge of their co-occurrence, alternations with, and substitution for common attacks, as well as by the therapeutic fact to be referred to further on.

We must bear in mind that no one symptom of epilepsy is pathognomonic or even has as much value as fulgurating pains have in tabes, or dysarthria in dementia paralytica. It is the co-occurrence and grouping, or the sequence of the symptoms which go to make up an inductive diagnosis, even in what at first sight seem very different conditions. What could be more different, on the surface, than an attack of *grand-mal*, an epileptic vertigo, or a maniacal manifestation of epilepsy?

Next, allow me to speak in detail of the diagnostic value of the individual symptoms of an attack.

(1) Loss of consciousness, is by some held to be a never-failing symptom, but if we admit Jacksonian spasms into the epileptic group, it will be found wanting in all cases of purely motor epilepsy. In some cases of *petit-mal*, those in which a momentary sense of stoppage of cerebral action, or a peculiar sensation constitutes the attack we cannot feel sure that consciousness is lost; we infer its momentary suspension in contradiction to the patient's positive as-

sertion. In some cases intermediate between *grand* and *petit-mal*, patients sometimes prove by repeating after an attack what was said or done before them, that the unconscious period was much shorter than we supposed. In psychic epilepsy it is not a simple loss of consciousness which obtains, but a peculiar different consciousness which cannot be recalled or reproduced after the attack; in other words, there is amnesia of all that took place in the seizure even if it lasted days, weeks or months. During the attack the patient has a consciousness belonging to the morbid condition of the brain underlying the attack; he *seems* conscious, answers correctly, does what he is bid, performs the ordinary acts of daily life, even to executing business matters and travelling. It is a state of consciousness not unlike that observed in trance, somnambulism and deep hypnotism. It is an unsolved problem whether the abnormal conscious state is recalled by the patient in subsequent paroxysms; in other words, whether we have here "double consciousness," in which the pathological state of the ego is continuous in succeeding attacks, just as the normal consciousness is continuous in the periods between attacks. An absolute barrier, as impassable, as that between life and death, which we term amnesia, separates the two states. What a startling problem this double life presents to the student of the human "soul."

I am disposed to classify procursive epilepsy, as newly described by Bourneville, with psychic epilepsy. The running is probably done in obedience to voices heard or visions seen (hallucinations).

After a paroxysm of psychic epilepsy some patients apparently recall a few features of the attack, but I am inclined to think that this is really a process of inferential reasoning rather than a true direct recollection. In the same way some patients know that they have had an attack of *grand-mal* or of *petit-mal*.

The extreme suddenness with which consciousness is lost in ordinary epilepsy is of considerable value for its differential diagnosis from syncope and hysteria.

(2) Dilatation and immobility of the pupil. This invariably occurs only in *grand-mal*, and forms an intermediate between this and *petit-mal*. It is often present in true *petit-mal*, and is not observed in most cases of psychic epilepsy. It is a symptom generally overlooked by the laity; and occasionally (as we seldom are able to witness attacks), it is desirable to instruct relatives how to detect the symptom to help us in diagnosis. In cases where there is doubt, for instance, as

FIG. 2. State of Consciousness in Somnambulism, Hypnotism (of a certain degree), some cases of Psychic Epilepsy and of Insanity; Double Consciousness. The states of abnormal psychic activity are united to one another but separated from normal consciousness by as complete a break as in condition one.

N, Normal conscious state. A, Attack (blank, or abnormally conscious).

to whether a convulsive attack is epileptic or hysterical, the determination of this sign is vital. It should be looked for at the onset of the seizure.

(3) Co-existent with dilatation of the pupil is pallor or an ashen-gray (livid) hue of the skin of the face. Why it occurs in the same cases that show pupillary dilatation is explained by the generally accepted theory that both symptoms are due to the same cause, that is, vaso-motor spasm occurring as a part of the general motor discharge at the onset of the attacks. The motor discharge (from the epileptic centre?) goes out by two channels: (a) through the common motor nerves supplying the striped muscular system generally (except the heart), and (b) through the vaso-motor nerves supplying the unstriped muscular fibres of the vascular system. In the iris it is a question whether the spasm is vascular (my own view, following Rouget) or simply muscular (dilating fibres contracted). Here again we have a symptom which, practically, is not of very great utility because it is often overlooked by witnesses; they often persist in saying that the patient's face was red or flushed or normal during the attack. This faulty observation is due to the fact that the observation is not made at the really initial stage of the seizure. It is a fleeting symptom, quickly succeeded in most cases by ordinary color, flushing, or intense turgescence.

(4) The spasm itself. It is most important to obtain as minute a description as possible of the first spasmodic movement of an attack supposed to be epileptic. The questions should tend to elucidate (a) the exact point of departure of the spasm (first movements or "signal-symptom" in organic epilepsy); and (b) the form or nature of the spasm. If you learn, for example, that the spasm always begins in the right fingers, you have a precious guide for your later pathological diagnosis. In the majority of cases the first movement is bilateral and general, often first noticeable in the eyes, neck and throat. It may be momentary, a simple stiffening of the body, as it were, congealing the patient in the attitude he happens to be in ("statue-like state").

As regards the form of spasm, in typical *grand-mal* careful observation always reveals two modes of muscular movement. One is a sudden rigid contraction (tonic spasm) of the entire muscular system, including the laryngeal and thoracic muscles. This constitutes the whole spasm in many cases of *petit-mal* ("staring-spells," "statue-like state"). It is momentary in duration, seldom lasting half a minute, contrary to the assertions of lay witnesses. In *grand-mal* there next occurs jerking or intermittent spasms of nearly all parts (clonic spasm), which may last a minute or more in rare cases. Co-existent with this we have congestion or purplish hue of the face, frothing, biting of tongue, emission of contents of viscera; continued unconsciousness. These symptoms of the second stage of a true epileptic attack are due to the asphyxial state produced by the first or tonic spasm. In *petit-mal* we have only the first or tonic spasm. In psychic epilepsy, though there may be complicated muscular movements, we never have spasm; the movements are co-ordinated and apparently voluntary.

It is of much importance to obtain a clear description (assisted by well-directed questions) of the form of spasm observed. In hysteria, for example, the tonic period is absent, and the jerking convulsions are usually more or less co-ordinated, dramatic and quasi-

voluntary. The asphyxial condition is not present, nor of course do we have the vaso-motor spasm (pallor of face or dilatation of the pupils). Malingers seldom know enough to produce the proper succession of tonic and clonic spasm, though they may produce a terrific convulsion and froth pretty well. In both hysteria and malingering the spasm is much prolonged—far beyond the limit of from one and a half to two minutes usually observed in epilepsy. Often, also, the spasms are much more violent in the non-epileptic states. As a part of the spasm, the condition of the eyelids is of paramount importance for diagnosis between hysteria and epilepsy. In the latter they are always(?) open, usually staring and fixed by tonic spasm, while the closed, quivering lids of the former condition are significant to the skilled observer as soon as he glances at the convulsed patient. I have been led by experience to attach very great value to these points.

(5) The sensory aura. I have spoken of the value of the "signal-symptom" or initial local spasm, as a help to the diagnosis of organic epilepsy and of the location of the lesion. The aura, so called, is of some importance also, by enabling us to locate quite accurately the seat of primary irritation in the sensory portion of the central nervous system. Just as a tingling sensation in the little finger is characteristic of a blow upon or an irritation of the trunk of the ulnar nerve, so do the sensory auræ of epilepsy point to irritation of some sensory nucleus or path. The sensory aura often coincides in location with the first spasm or "signal-symptom" (for example, in one hand). In most cases, however, the sensation just preceding the loss of consciousness is quasi-visceral; apparently starting from the stomach, the abdomen, or one iliac region. When the aura is persistently placed deep in the so-called ovarian region (which is not at all the region of the ovary) it gives rise to the idea that the epilepsy is caused by ovarian disease. On such a flimsy basis, re-enforced by the fact that attacks are more frequent, or wholly confined, to the menstrual period, a whole theory of ovarian epilepsy was erected a few years ago and many women needlessly mutilated by surgical treatment. I have seen several cases in which ovariectomy, single or double, had been performed without the slightest effect on the disease. To be logical, the stomach, small intestines, sub-sternal parts, limbs, etc., should be excised to cure epilepsy.

The true interpretation is, that a centrally-placed irritation produces a referred sensation in the distribution of sensory nerves arising in or passing through the seat of the lesion. Thus the very common sub-sternal and gastric aura represents, to my mind, a lesion of the floor of the fourth ventricle, and autopsies go to support this view. I have a case of *petit-mal* under treatment in which for several years the aura was hypo-gastric (or apparently uterine). It gradually ascended to the middle of the abdomen, and is now nearly a gastric aura. This cannot be explained by any theory of extension of the lesion from the uterus to the intestines, and thence to the stomach; but it is very significant of a transfer of the lesion causing attacks, to a different level of the medulla oblongata.

If you will allow me here a therapeutical digression, I will say that the determination of the signal-symptoms and of the sensory auræ is of value as a guide to the abortive treatment of attacks on the principle advanced by Brown-Séquard, namely, that an

artificial irritation applied to the seat of aura (or signal-symptom) often arrests the attack. For example, in cases where the signal-symptom, or aura, is in the hand or in the foot, the sudden application of a ligature on the wrist or ankle often prevents or aborts the attack. The fact is ancient, but the true theory of its application was first given by Brown-Séquard; a centrifugal irritation inhibits the central discharge. I have been very successful in such cases by having the patient wear a bracelet or anklet of metal or cord, to be suddenly and severely tightened as soon as the patient has the first sign of the attack. Gastric and sub-sternal aura are best met by an irritation to the fauces, a swallow of table-salt, or an inhalation of spray of carbonic acid. The application of these mechanical means, as well as the inhalation of nitrite of amyl (irrespective of the location of the aura), is limited to the few cases in which some little time intervenes between the occurrence of the premonition and loss of consciousness, and the patient has time to call for help, or to open a bottle and smell it.

(To be continued.)

### THREE CASES OF TUMOR OF THE UTERUS.

BY JOHN HOMANS, M.D.

#### A LARGE FIBROID TUMOR OF THE UTERUS WHICH HAD OBSTRUCTED LABOR REMOVED BY ABDOMINAL SECTION.

Mrs. B., thirty years old, was sent to me in December, 1890, by Dr. J. S. Benson, of Chatham, N. B. She had been confined for the first time seven weeks before I saw her. Labor was delayed by a tumor, which filled the vagina more or less, and prevented the descent of the child's head. A consultation was held, and Caesarian section was contemplated; but the tumor gradually receded, and the child was born without interference.

On examination I found a tumor about the size of a small cocoon in the left side of the pelvis, in the iliac and sacral regions. It was slightly movable, and the uterus could be moved independently of it. The uterus was pushed up in the right pubic and inguinal region; it was movable, and had a depth of four inches.

My reasons for operating were: that the tumor had obstructed labor, and if it increased in size, particularly if it contracted adhesions, it might totally prevent delivery by the natural passages in a second pregnancy. Second, it seemed possible to remove the tumor at once; whereas, if it became fixed, it might be impossible to do so. Third, the patient had come a long way, and she and her husband and friends were ready and prepared for the operation.

On December 8th, I opened the abdomen by an incision about four and a half inches in length. The left ovary, of large size, presented itself beneath the incision. Beneath and behind the ovary was felt the tumor. This was seen to be solid and to lie beneath the peritoneum of the left broad ligament. The uterus and ovaries were pulled out and bent forward on the pubes, and an attempt was made to pull out the tumor in its

peritoneal envelope, but this could not be done. Consequently a longitudinal incision was made through the peritoneal envelope of the tumor, and through this opening the fingers were passed and gradually inserted between the peritoneum and the tumor. After awhile the whole tumor was peeled out of its bed. It was then found to be connected with the under side of the body and neck of the uterus by a stalk about one and a half inches thick; this was tied and the tumor cut off. None of the uterus proper was removed. The tumor was a pedunculated fibroid. The large pocket in the broad ligament from which the tumor was removed was sponged out, but was left otherwise undisturbed. The wound was closed in the usual way without drainage. The tumor weighed two and one-half pounds, and measured seven by four and one-half by three and one-half inches, and was a multiple fibroma united beneath one smooth, even envelope.

It is now two weeks since the operation, the wound is united by the first intention, and recovery seems assured.<sup>2</sup>

#### VAGINAL HYSTERECTOMIES FOR CANCER.

Mrs. M., forty-four years old, the mother of two children, the youngest of which is twelve years old, entered St. Margaret's Home, December 16, 1890. In December, 1889, she had felt a bearing-down sensation; in April, 1890, a sudden and transient sharp pain; and in August an inoffensive discharge began, and has continued to the present time. Other than these symptoms she has had no pain nor discomfort. The growth was discovered in August by Dr. Goodspeed of Worcester.

On examination I found an epithelioma, involving the vaginal portion of the os and neck of the uterus, and nearly filling the cavity of the vagina. After two days of antiseptic douching, I removed the uterus by vaginal hysterectomy, making an incision entirely around the growth in the sound mucous membrane, and then separating the uterus from the bladder and rectum by the fingers. The broad ligaments were clamped on each side, and the forceps, four in number, were left hanging out of the vagina. Recovery has been uneventful; temperature normal; but little discharge. The clamps were removed on the fourth day, that is, three days after the operation.<sup>3</sup>

#### MALIGNANT ADENOMA OF THE UTERUS, REMOVED BY A COMBINED METHOD OF ABDOMINAL AND VAGINAL SECTION.

Mrs. W., thirty-four years old, married; never pregnant. Bloody discharge from uterus for two years, accompanied at times with pain, rendering her unfit for her ordinary occupations, and much of the time quite offensive. A fat, well nourished, strong woman. Had been treated by curetting in New York and elsewhere, and was referred to me by Dr. Chandler, of Montpelier, Vt.

On examination I found that the uterus was as large as it would have been at the fifth month of pregnancy, and this enlargement was symmetrical and pyramidal. On vaginal examination I found the os thin, the neck obliterated, and within the os a soft mass, feeling much like placental tissue. I passed the uterine scoop freely within the uterus, and tried to pull out the growth with forceps, but I only got bits

<sup>1</sup> Reported at the meeting of the Boston Society for Medical Improvement, December 22, 1890.

<sup>2</sup> The patient subsequently went home well.

<sup>3</sup> The patient made an uninterrupted recovery.

of tissue resembling boiled sago. I could not empty nor get out the growth.

As the uterus was too large to be pulled through the vagina, I decided to do a double operation, and as I did not want to put my hands into the abdomen, after working in the vagina, I asked Dr. Mixer to open the abdomen and remove the tumor, after I had separated its attachments to the bladder and rectum by vaginal hysterectomy. Accordingly I proceeded as if I expected to remove the tumor through the vagina, and when I had separated the uterus from the bladder in front and from the rectum behind, and had clamped the broad ligaments from below, Dr. Mixer opened the abdomen and delivered the tumor, separating what attachments I had been unable to reach, owing to the size of the tumor and the smallness of the vagina. There was but little bleeding.

I think the removal of this tumor in any other way would have been well-nigh impossible.

Dr. Whitney made the following report on the tumor:

"The uterus measured eight centimetres internally, and the walls were four centimetres thick. From the interior hung polypoid projections—the ends of many of these were sloughing. The wall of the uterus could be divided into two layers, an inner, measuring about two centimetres, and filled with numerous small cysts containing a clear fluid. The outer layer, also of equal thickness, represented the muscular wall of the uterus.

"Microscopic examination showed the inner layer to be formed of numerous cysts with smooth walls, separated by a fibrous tissue framework. In this were also to be found tubular glands covered with large cylindrical epithelium.

"As far as the examination has gone, it points to the growth as a malignant lymphangiectatic fibrous adenoma.

"The relations of the cystic to the muscular wall are well seen in the frozen section stained green, and placed in the bottle which accompanies this report."

#### THE REMAINS OF A BROKEN LEAD-PENCIL (SURROUNDED BY PHOSPHATIC DEPOSITS); AND THE METAL TIP OF THE PENCIL REMOVED FROM THE BLADDER BY PERINEAL SECTION.

BY GEO. H. MONKS, M.D., BOSTON.

Last spring a patient came under my care in the surgical wards of the Carney Hospital, with a violent cystitis resulting, as he said, from the presence of a lead-pencil in the bladder. He stated that sometime during the preceding October he had pushed a lead-pencil into his urethra for the purpose of "opening the passage for his water to run." He declared that he had suffered with stricture, and that he had introduced the pencil after a vain attempt to urinate. The patient was rather stupid, and he would not or could not give a very satisfactory account of the affair.

The pencil, when introduced, was between three and four inches in length. It was an ordinary lead-pencil, with a piece of rubber attached to one end, while the other was bluntly pointed. The rubber was kept in place by a metal collar.

In some unexplained way the pencil, while in the

urethra, escaped from the patient's grasp, and managed to slip into the bladder:—a circumstance which renders the story of the stricture extremely improbable.

Shortly after this, the patient was obliged to seek surgical assistance on account of the intense pain, violent tenesmus and frequent desire to micturate, which resulted. He said that he had been twice etherized and operated upon, and that he was told after the operations that attempts had been made to remove the pencil through the urethra, that the pencil had been crushed and several fragments removed, including the rubber tip, and that the nickel collar still remained in the bladder, with possibly a few fragments of the pencil itself.<sup>1</sup>

Months went by until the patient came to the Carney Hospital. This was in April. He was suffering tortures from pain and tenesmus. The urine was filled with sediment, and its odor was foul. A foreign body,—it seemed like a stone,—was readily detected by the searcher, and it was decided to do perineal section. On April 12th, the patient being under ether, I opened the bladder by the perineal route, the incision being made upon a staff and in the median line.

With my forefinger pushed well into the wound I could feel the foreign body; it was rough on the outside like a stone. Owing to the depth of the perineum I had some difficulty in catching the body with forceps and extracting it.

At last I was successful and it was removed. It was a little over two inches long (see Fig. B), was slightly curved and appeared to consist principally of phosphatic deposit. A considerable piece of macerated wood protruded from one end, while the other end was smooth and was moulded into a blunt point. During further examination of the bladder the metal collar was found and removed. This collar (see Fig. A) was distorted, its shape suggesting that of a cocked-hat; and from one end projected macerated wood. The thread on the collar was quite distinct. The cut represents the two bodies in their actual size.

The bladder was thoroughly washed out, a drainage-tube inserted and a T-banage applied.

The patient's recovery was rapid and uninterrupted. The bladder was washed out daily with antiseptic so-

<sup>1</sup> I subsequently learned from the surgeon in charge of the case that his intention had been to make an opening into the bladder later, and remove the metal collar, but that the patient would not submit to another operation and had disappeared.

<sup>2</sup> The patient died on the fourth day. There was no autopsy.

lutions, and all signs of cystitis gradually disappeared. The perineal wound healed rapidly and urine began to flow through the penile urethra. About three weeks after the operation the patient left the hospital with a small perineal opening, through which occasionally escaped a few drops of urine.

## REMARKS.

The larger specimen was evidently a heavy phosphate deposit about a nucleus of macerated pencil-wood, part of which I have already mentioned as protruding from one end of the mass. The smooth, blunt point at the other end was of such shape as to suggest that it had rested either in a pocket or in the internal meatus of the urethra.

Prof. E. S. Wood, to whom the specimen was shown, was inclined to think that the body lay on the floor of the bladder with its convexity downwards, and that the blunt-pointed extremity rested in a pouch, probably behind the prostate.

The distorted shape of the metal collar, already referred to, suggested that it had been squeezed and flattened at its two extremities by the powerful jaws of the lithotrite, but that, *unfortunately for extraction*, this flattening had been made in different diameters at the two ends, thus making a body whose smallest diameter was too large to permit its extraction through the ordinary urethral tubes.

It would seem that the operation of crushing and washing should be restricted to the removal of calculi and of such substances as will, when crushed, break up into separate fragments, of a size and shape such as will readily engage the tube and pass through it; and that all other bodies should be removed by an immediate opening into the bladder.

I should not neglect to mention that the bodies, at the time of their removal, were very foul smelling. They were kept for three days in fresh running water, and even at the end of that time, the odor about them was distinctly perceptible.

## FIVE CASES OF LAPAROTOMY FOR PELVIC ABSCESS.

PERFORMED BY DR. J. C. WARREN,  
*Surgeon at the Massachusetts General Hospital,*  
REPORTED BY HARDY PHIPPS, M.D.,  
*Formerly Surgical Intern.*

THE following five cases of laparotomy, all occurring during a few months, at the Massachusetts General Hospital, in the service of Dr. John Collins Warren, may be found of interest in showing the obscurity of diagnosis in three cases of tubercular peritonitis, associated with acute pelvic inflammation, and the tendency to cure after operation.

The two cases of simple pelvic inflammation, one with a favorable outcome, the other fatal, are for convenience classed with the others. The successful case making with the three tubercular ones a group of four, in which the sinus formed when drainage was established, continued to discharge for several months after the operation.

The first case is one of tubercular peritonitis, undoubtedly of pelvic origin, and of at least one year's duration. The tubercular element in this case, which was not accompanied by an increased amount of fluid, was not suspected until discovered at the time of an

operation for encysted peritonitis of the right side of the pelvis. The result in this case has been good, the patient being in excellent condition eighteen months after the operation, in spite of the fact that the whole peritoneum, as far as seen, was studded with tubercles, while the history of an attack of pleurisy while the patient was under observation, might point to the extension of the same process through the diaphragm.

R. A., unmarried, twenty-seven years old, entered the hospital February 10, 1888. Her family showed no tubercular tendency. Her own health had been always good with no unusual abdominal or pelvic symptoms. For two years she had been slowly losing weight and strength, but without any localizing symptoms. This had finally culminated in two attacks of very profuse menstruation, the second of which brought her to the hospital.

A poorly developed, poorly nourished woman was found. The chest was normal, the abdomen somewhat distended, but containing no free fluid. There was some diarrhoea. A well-defined area of dullness, very tender on pressure, was found in the right iliac region. The uterus was not movable, and there could be felt at the right of the uterus a thickening. The temperature was 102° F., the pulse 112.

The patient remained under medical treatment for two months. The urine at first comparatively clear, later contained large quantities of pus, accompanied by a fall in the temperature and a gradual improvement in the general condition. The patient was at the end of this time discharged in fair condition, with normal temperature and pulse, perfectly clear urine and no abdominal tenderness, but with a thickened mass still to be felt at the right of the uterus. During this time there had been no symptoms pointing to the general abdominal cavity, but there had been an intermittent attack of pleurisy of the lower left chest.

The same patient was admitted eight months later. There had been pain in the former seat at every menstruation since her discharge. The condition now was bad. The temperature 102.8°, the pulse 112. Fluctuation in the right iliac region was very clear, and there was some general abdominal distention. The patient was operated on December 15, 1888. An incision in the median line showed the intestines everywhere matted together and thickly studded with gray and yellowish tubercles, varying in size from milium tubercles to those more cheesy in appearance, as large as peas. A few of these removed, showed the characteristic appearance of tubercles. There was no excess in the amount of free fluid. On separating the adhesions between a few coils of small intestines of the right side, a cavity containing about a pint of very foul pus was directly opened into. This cavity was cleaved with warm water, and a drainage-tube put in; the general peritoneal cavity was closed.

The recovery in this case was excellent. The discharge, at first profuse, soon diminished. The tube was removed at the end of a month, but the sinus still discharged.

Eighteen months from the time of the operation the woman was seen. She was in excellent condition, had married, but not been pregnant. The chest was normal. There were no symptoms whatever of any abdominal or pelvic trouble. The old sinus continued to discharge for ten months after the operation. Just above this sinus there was now a small ventral hernia.

The second case is one in which symptoms were

entirely absent until an attack of acute pelvic inflammation, after the insertion of a pessary for retroversion, required an abdominal section, which showed the existence of a general tubercular peritonitis, without effusion, and apparently not of recent origin.

R. C., a servant girl, unmarried, twenty-five years of age, entered the hospital January 14, 1889. One sister had died from phthisis. With the exception of backache, for the past three years her general health had been good. Two weeks before entrance a pessary had been inserted to correct a retroversion. This was very soon removed, on account of pain, but severer symptoms with a chill soon followed. At the time of admission the girl was in good condition, the pulse 112, temperature 102.2°. There was some general distention of the abdomen. A vaginal examination showed a thickening behind and to the right of the uterus.

As the patient got no better but continued running a very high evening temperature, the abdomen was opened on the 5th of February. A median incision showed the mesentery thickly studded with small cheesy tubercles. The intestines were in the same condition and firmly adherent to each other and to the walls. The amount of fluid was very small. The adhesions were separated with some difficulty, but no troublesome amount of hæmorrhage, down to the posterior cul-de-sac, where a few drachms of thick, cheesy pus were found. The temperature immediately fell to normal, but two days later again rose, accompanied by a discharge of foul-smelling pus from the tube which was placed in the posterior cul-de-sac, soon followed by one fecal in character. The patient was in a very bad condition for some time, with fever, rapid pulse, and discharge of feces through the abdominal wound. The convalescence was slow, a fecal fistula remaining for three and a half months after the operation. The patient was discharged about four months after the abdominal section. The wound was then entirely healed, excepting a small sinus discharging a few drops of pus each day. The general condition was very much improved, with a normal temperature and no abdominal symptoms.

The next time the girl was seen was seventeen months from the operation. Her general condition was now excellent. She was at work, and had gained about thirty pounds in weight. There were no abdominal symptoms, but the backache still continued, and about once a month the old sinus, now generally crusted over, discharged a few drops of pus.

The third case can hardly be classed as one of undoubted tubercular peritonitis, as the nodules which were seen, were few in number, and none were removed for microscopic examination. This case shows a long-continued discharge from the cavity of an old pelvic peritonitis, probably tubal in origin, but is one in which any more radical operation than the one performed would probably have been fatal at the time.

L. O., a married woman, twenty-seven years old, was first seen February 5, 1889. Her family history was good, her own health had been fair. Though married four years, she had never been pregnant. Menstruation during the last few years had been irregular and painful, with sometimes nausea and headache. The last two times she had suffered from vomiting and abdominal pain, with a very much increased flow. At the time of entrance the temperature was 101°, the pulse 108, the general nutrition poor, the abdomen

slightly distended. On examination a fluctuation could be felt to the right and behind the uterus, which was displaced to the left.

The abdominal cavity was opened on the 17th of February. An abscess containing about twelve ounces of pus was found rising out from the right side of the pelvis. The cavity was washed and a drainage-tube inserted. No attempt was made to discover and remove the cause of the trouble, as the patient's condition was very poor. On the peritoneal covering of the small intestines were a few cheesy-looking nodules, resembling old tubercles. None were removed for examination.

Convalescence was slow. At the time the patient left the hospital, about a month from the operation; the general condition was much improved, though the sinus still discharged. Seen a year later, she stated that she was never better, and the sinus had closed.

Case No. IV shows a sinus still discharging a year and a half after an operation in which, as in the last case, an encysted purulent peritonitis, probably tubal in origin, though due possibly to the breaking-down of an hæmatocele, was opened and drained without any attempt to find the origin of the trouble.

K. D., an unmarried woman, twenty-five years old, well developed and well nourished, entered the hospital January 21, 1889. Menstruation had always been regular and without pain. While lifting a trunk during her catamenial period, three weeks previous, she felt something "give way" in her left side, followed by slowly increasing pain. By night the pain in the left inguinal region was very severe, accompanied by faintness and a well-marked chill. Pain and chilliness increasing for a week, she noticed she was increasing in size, and came to the hospital.

At entrance the temperature was 100.8°, the pulse 100, the condition good, the face pale and expression anxious. The bowels were regular.

In the median line, extending from the pubes to the umbilicus was a very prominent oval swelling, looking not unlike an enormously distended bladder. This area was flat, tense and fluctuating. The flanks were tympanitic. A vaginal examination showed the uterus pushed to the right. No operation was done for two weeks, the tumor increasing slowly in size. Finally, on the 5th of February the abdominal cavity was opened, and a large sac, apparently covered by peritoneum, was found in the median line, extending down into the pelvis. The general cavity was normal in appearance. The abscess containing over sixteen ounces of very foul-smelling pus, was cleansed, its walls brought up to the abdominal wound, and the peritoneal cavity closed. A tube was left in the abscess cavity.

The recovery was good, pulse and temperature falling immediately. The tube remained in place for nearly a month, but the discharge continued after its removal.

One month later the girl returned. The sinus was then four inches deep and still troublesome. A stitch was removed, and the patient again discharged.

Three months later she was again seen, with some abdominal pain, and in a rather poor condition. The sinus was still as before. After remaining quiet a few weeks, she was much improved. Last seen, nineteen months from the time of the operation; she was in fair condition, doing house-work, but still required to wear a pad to catch the constant discharge from the wound. No examination was made.

The fifth case occurring about the same time was one of old pelvic inflammation, in which existed a cavity containing pus from the surrounding inflammation, urine from a fistulous opening into the bladder and fæces from the rectum.

E. L. D., married, thirty-three years old, entered January 1, 1889. She had had four children, but no miscarriages. Two years before she had been very ill with "pelvic peritonitis," the cause of which was unknown. She had since been an invalid. Three months previous, she had increased trouble, followed by a discharge of pus from the bladder. Shortly before entrance she had been seen by Dr. J. W. Elliot, who advised her to come to the hospital.

An examination at entrance showed a general matting together of the pelvic contents. There was also considerable fever. The patient's condition was very poor, and improved very little under a month's careful treatment. The urine during this time before the operation contained pus and fecal matter, accompanied by frequent passing of gas by the urethra.

The patient was operated upon February 7, 1889. There was no indication of trouble outside of the pelvis, but here there were general adhesions. A thickened mass, just to the left of the uterus, was opened, and about a drachm of pus found. The right tube and ovary were in a very fair condition. The patient rallied well, but died five days after the operation from exhaustion.

This case was regarded as a very unfavorable one for operation, owing to the patient's feeble condition; but as cure seemed impossible by other means, the patient's strength was improved as much as possible, and a comparatively favorable moment selected for opening the suppurating cavity.

## A NOTE ON EXTRACTS FROM TUBERCLE CULTURES.

BY J. A. JEFFRIES, M.D.

I THOUGHT it might be of interest to report a few of my results with extracts of pure cultures of the tubercle bacillus. I began a year ago to make extracts and study their effects on guinea-pigs, my ultimate object being to produce immunity or find some form of treatment. At first I used alcohol (absolute and dilute), ether, chloroform and benzole, and found that my results were very variable, not regular. After this, in the early part of last summer, I began to prepare glycerine extracts, reasoning from the power of glycerine pepsin extracts. With glycerine I soon found that more or less definite reactions could be produced by large doses in healthy guinea-pigs. There would be swelling at the point of injection, evident discomfort, an increase of urine and at times fever, etc.

Owing to sickness in my family nothing more was done until after Professor Koch's first publication. I at once found that my glycerine extracts produced a much more marked effect in tuberculous than in healthy guinea-pigs. The former, after a dose of half a cubic centigramme, would, in the course of a few hours become very sick, huddle up in a corner with hair on ends, shiver, and in some cases pant. Apparently the amount of urine was increased. Tuberculous guinea-pigs, while in the reaction, could be laid down anywhere and did not run away.

<sup>1</sup> Read at the Boston Society of Medical Sciences, January 27, 1891.

All my animals, both those inoculated with the extract alone and those first poisoned with pure cultures of the tubercle bacillus were then put under like conditions to note results as to longevity. Unfortunately a bull-terrier made a raid on my guinea-pigs during the latter part of December, and again on the 8th of January, killed most of my control animals, and thus ruined the experiments as to final results. So that all I can affirm is that some of my glycerine extracts of about forty-five per cent. final strength, allowed to stand at a temperature of  $37\frac{1}{2}^{\circ}$  C. for one week contain a substance which causes a much more marked reaction in tuberculous than in healthy guinea-pigs; and that for two or three weeks after the former appeared better than the simply tuberculous control animals.

I have not, of course, got far enough to say if such an extract will invariably work, or to what extent it will mitigate the action of the bacilli. Nor do I yet know how old a culture should be, the best medium to grow it on, nor if the extract should be made neutral or slightly acidified. I might add that I found no signs of tuberculosis in a guinea-pig which had received one and a half cubic centigramme of my extract in divided doses, and was then inoculated with tubercle culture in the abdomen. Too much weight cannot be laid on this, however, as the animal was very badly crushed by the dog eighteen days later — other guinea-pigs inoculated in the same way with cultures died of tuberculosis in about a month.

In closing, I would state that this is only read in view of Professor Koch's latest announcement as printed in the newspapers of January 15th, from which I should judge that, working in somewhat the same line and stimulated by his first article, I have got something on the same principle, but am not sure, as I have been unable to procure an atom of the paratoid for any purpose.

## Clinical Department.

### A NEW SOURCE OF ARSENIC POISONING.

BY WILLIAM N. SWIFT, M.D., NEW BEDFORD.

F. H. S., six years old, perfectly healthy baby. After the age of two, he began occasionally to look badly. At these times his bowels were constipated, his breath rather offensive, his tongue coated. He was somewhat salivated, and had at times a few superficial ulcers on the mucous surface of the lips, gums, or tongue. No explanation could be found for this condition, except that he always had a good appetite, and was in the habit, unless watched carefully, of bolting his food. His diet had always been regulated with much care.

In January, 1890, he had the epidemic influenza, and as he was at its onset in one of his debilitated conditions, he was very much pulled down by the illness. During the summer he was in the country, and was perfectly well. When he returned home, he began, in a short time, to look badly. He became anæmic, began to lose weight, and his muscles became soft and flabby. He was constipated. His tongue was coated, and the whole mucous membrane of the mouth became soft and spongy. His breath was offensive. He complained of weakness and occasional cramps in the muscles of the legs when walking. He had to be taken up two or

three times at night to prevent him from urinating in bed, and he wet his clothes often during the day.

The plumbing of the house was examined, and found free from any defect. The boy's urine was then analyzed, and arsenic was found. No quantitative test was made, but the amount was considerable. The question was then, what the source of the arsenic might be? The carpet, curtains and furniture-covering were analyzed and found free from arsenic. A border and dado of a pictorial paper about the room was known not to contain arsenic. The wall between these was painted a peacock blue, and this paint was found loaded with arsenic. The painter, who had painted the room six years ago, said the color was obtained by mixing prussian blue and a green. The green pigment undoubtedly contained arsenic. The paint was mixed with lead and oil, and had a smooth, glazed surface.

The patient was sent inland for a change, and he began to improve at once. Since eliminating the source of poisoning, the boy has been perfectly well.

In looking back on the different attacks that the child had had, during the four years that he had been exposed to the poison, it was noticed that whenever he had been away from home and had come back to this room, the symptoms of debility and stomatitis had developed; but that, after living in the room for some time, he seemed to become used to the poison, and improved somewhat.

The case seems to me interesting, because the evidence, to my mind, is conclusive as to the cause of the symptoms; the obscurity of the symptoms themselves; and the unusual source of the arsenic; showing that paint should be analyzed, as well as paper and furnishings, in sleeping-rooms.

## Reports of Societies.

### THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

#### THE PROGRESS OF CYSTOSCOPY IN THE LAST THREE YEARS.

DR. W. MEYER, of New York, read a paper on this subject. He said he should confine his remarks to that part of the subject which bore directly on the diagnosis and treatment of kidney disease, with the help of the cystoscope. He thought it would be to the point if he were to read the histories of two cases which had come under his observation in private practice, and which he thought would serve to illustrate the gratifying change which had resulted from the use of the instrument.

CASE I. Mrs. ———, forty-five years of age, had come under his care in 1887. Two months previously she had been operated upon for an inflammation which had been set up in the left (floating) kidney. The lumbar incision had revealed a cystic degeneration of the organ. The wound had healed, with the exception of two small sinuses which had remained in the scar and gave continuous exit to sero-pus. For more than a year the patient had felt benefited by the operation, but an ever increasing bladder tension had made life miserable, and some relief was sought for by further

operation. This was denied on the ground that degeneration of the kidney rarely occurred as a unilateral disease. Some active interference had, however, become necessary, and the speaker had resorted to cystoscopy for the purpose of ascertaining the exact condition of things and the relative functional activity of the two kidneys. He had found the following condition: There was catarrh of the bladder, the minutest blood-vessels being injected. The point at which the orifice of the left ureter should have been seen presented a curiously folded growth, consisting of the swollen and inflamed mucous membrane. He had suddenly noticed a jet of fluid mixed with small and large flakes and shreds which had come from a somewhat retracted spot at the top of the mass. A few minutes later a long thread of pus was slowly making its way out of the opening into the bladder. Examination was now directed to the right ureter, to ascertain, if possible, the character of the discharge from it. The orifice was being pushed forward and retracted alternately, as was normally done with the out-pouring of each jet of urine thrown into the bladder. Comparing the ejection of the two ureters in point of time, he had found that there was on the right side a jet of clear urine every twelve, fifteen, twenty and twenty-five seconds, and from the left only every four, six and eight minutes. The question then arose: Would the work of the right kidney be sufficient if the left one were removed? That it would be so, seemed to be amply proven by the cystoscopic examination; and if this was the case, the diseased organ, which caused the repeated attacks of ureteritis and septic fever, from which the patient now constantly suffered, was a burden which could and should be removed. On these grounds a favorable prognosis was made in regard to the nephrectomy, provided the immediate effects of the operation were withstood. The operation had been undertaken by the speaker, and the kidney was found in a condition of extensive cystic degeneration. The patient had done well so far, though the urine was not yet clear. Future cystoscopic examination must determine whether this was the result of some bladder trouble or the impairment of the right kidney.

CASE II. Was that of a woman, seventy-eight years of age, in whom the cystoscopic examination had revealed the fact that nothing but thick pus descended from the left kidney. As the daily average of the urine voided was thirty to forty ounces, the prognosis as to the functional condition of the other kidney was, of course, favorable. Nephrectomy was accordingly performed, and it was found that the enucleated kidney was enlarged and sclerosed. After the operation the amount of urine had never varied except in the first twenty-four hours. This patient was making a rapid recovery.

As the result of his work so far, the speaker had drawn the following conclusions: (1) Cystoscopy was an easy and harmless examination; its successful employment required experience. (2) That in all renal bladder diseases cystoscopy had to be practised, if necessary repeatedly, before operative interference for diagnostic purposes was resorted to. (3) That it should be performed as a *dernier resort* after all other well-known means for making a diagnosis had been exhausted. (4) If properly applied, cystoscopy would generally clear up an obscure disease of the bladder. (5) There were a number of causes which made cystoscopy impracticable. (6) In most cases we could

<sup>1</sup> G. 1891. 10th Annual Meeting, held at Albany, February 3, 5, 1891. Continued from page 120 of the Journal.

determine, with the help of electric illumination of the bladder, whether we had to do with a disease of the bladder or of the kidneys. (7) We could then find out whether only one kidney was diseased or both. (8) We should soon be able, in the great majority of cases, and with the use of instruments at present in process of perfection, to catheterize the ureters and gather the urine from each kidney separately. (9) We could make out in certain cases, by timing the frequency of the jets at the orifice of the ureters, whether the one kidney was doing the work for the other which was diseased. (10) That these facts would tend to make superfluous a preliminary section or a perineal invasion for diagnostic purposes, as well as a nephrectomy performed for determining the action of the other kidney. That this will tend to greatly widen and strengthen our means for giving the indication and prognosis of nephrectomy.

#### A PLEA FOR RAPID DILATATION. HOLT'S OPERATION IN THE TREATMENT OF URETHRAL STRICTURES.

DR. F. R. STURGIS, of New York, read a paper with this title. He said that among the many methods of treating urethral strictures in the male, one which presented to his mind many points of advantage over urethrotomy, seemed to have been overlooked, and that was rapid dilatation, or division by means of Holt's instrument. The advantages were: first, the avoidance of severe hemorrhage; second, the avoidance of severe chill; third, the lessening of the dangers of septicæmic complications. It was well known how possible, and even fatal, bleeding might occur as a sequel to internal urethrotomy. Such personal experience had led him to adopt the method of Holt. Since then he had never had an instance of hemorrhage in which the bleeding was not easily controlled by the use of cold or stiptic injections. It had been in former times his practice to guard against the occurrence of chills by the administration of quinine and opium. He had, however, come to the conclusion that this was generally an unnecessary precaution. He saw that the patient emptied the bladder before and after the etherization, if desirous of doing so. He never left an instrument in the urethra; he thought it unnecessary and provocative of chills. He had never seen a case of septicæmia occurring as the direct result of rapid division. The contraindications for the use of this method, and which were still more so to any cutting operation, were very tight strictures with spasmodic contraction of the canal, renal disease, predisposition to chill after the slightest examination of the urethral canal. In all these conditions, if operation was imperative, external urethrotomy was to be preferred. In suitably selected cases, he thought better results would always follow division. Fewer relapses would take place if proper care were taken to observe the after-treatment with sounds. His conclusions were: that division was comparatively free from danger, that it could be performed under unpromising circumstances, and that it would be followed by satisfactory results.

DR. SENECA D. POWELL, of New York, said that the last speaker had omitted one of the advantages which dilatation possessed over the knife, and that was the separation of fibres at different points around the circumference of the canal, avoiding the tendency to recontraction at the point of incision. Then again, it was customary in using the knife in the urethra to allow

the canal to be undisturbed for four or five days, except a soft catheter was passed to draw away urine; and during this time adhesions were taking place, which prevented the operation being as beneficial as it would otherwise be. In 1881 he had brought before the profession a divulsor, the construction of which permitted the dilatation of the entire canal at once, the division being made by four plates instead of two.

DR. DANIEL LEWIS, of New York, had never seen a case of rapid dilatation or of cutting which did not require as much work to keep the canal open afterward as would have served to keep it so without these methods; patients came to his office with their boots full of blood, after these operations, and then required attention by sounds for months afterwards. He thought that in most cases the desired end could be equally well accomplished by gradual dilatation.

DR. W. MEYER thought that if a stricture was cut thoroughly and correctly, and dilated for some time afterward, the stricture would not require subsequent test by the bougie, but if gradual dilatation were performed, the patient would have to test the stricture during his whole life.

DR. POWELL said he must remind Dr. Lewis that the meatus was the narrowest part of the canal, and that it was impossible to dilate strictures of large size with a conical sound without first splitting the meatus. While the patient was comparatively young, and the tonicity of the bladder and other muscular strictures concerned in voiding the urine remained unimpaired, the meatus did not play so important a part, but later in life it acted as a nozzle to carry the urine away from the patient while voiding it. In division the integrity of the meatus need not be interfered with. He did not see any reason why deep strictures should not be divided.

DR. MYNTER said that the safest operation was that of perineal section, and after that came the use of the Holt instrument. Cutting a stricture was a dangerous operation; and he certainly would never interfere at a point below four inches, and then, if operation was imperative, he would do an external one.

#### TUMOR OF THE CENTRUM OVALE.

DR. L. C. GRAY, of New York, read a paper with this title. He narrated the case of a patient who had suffered from motor paralysis and paralysis of the muscular sense. At the autopsy a round-cell sarcoma about the size of a hickory nut was found, one-fourth of an inch beneath the cortex, at the junction of the leg and arm centre of the posterior central convolution. The patient, a man of thirty-eight, was brought to the speaker from Richmond, Va., by Dr. I. H. White, two weeks after motor paralysis had begun in one lower extremity. As there was a large tumor in Scarpa's triangle, and as an angioma had been removed some time before from the popliteal region, Dr. Gray was lead to believe that the symptoms were caused by an intracranial tumor. There was motor paralysis of one lower extremity and paralysis of the muscular sense, slight headache, but no mental symptoms whatever. The patient was advised to go home and settle his affairs, and to have trephining done if he grew worse. Two weeks after, he was brought to New York, and was found to have a motor paralysis and a paralysis of the muscular sense, also of the upper extremity on the same side as the paralysis which had first appeared. He was gradually becoming comatose. The headache

was very much worse. There were no changes in the optic disc; there was very slight impairment of the tactile sense; and no motor or sensory disturbance beyond that mentioned. The patient was operated upon by Dr. Wyeth, but neither by palpation or by exploration could any tumor be found. Death had occurred two days after the operation; and at the autopsy the growth was discovered, as above described. The speaker said that neurologists were divided in opinion as to the exact locations of the muscular sense; and he thought that this case was unique, as indicating within a period of very rapid development, the precise locality.

DR. J. LEONARD CORNING thought that the exact localization of the cerebral function, in a strictly mechanical sense, was hardly to be looked for. He did not think that cerebral surgery was going to do for us what had been promised for it. Less and less of it would be done; and the little that was undertaken would be restricted to the cases of so-called Jacksonian epilepsy, and where there was reasonable proof of the existence of the tumor near the surface of the brain, and that it was probably non-malignant in character. This would narrow the field very much, as, with the exception of the syphilitic growths, neoplasms of the brain were for the most part malignant. He should like to ask if Dr. Gray would advise operation in the case of deep-seated tumors. If he did not find the growth by puncture, would he cut through the cortex, and strip it off until he did?

DR. GRAY said that he should not hesitate to cut down in every direction in cases similar to the one of which he had spoken. Here the man was in a somnolent state with death at his heels. If the end were hastened by the scalpel, it was only justifiable euthanasia.

#### TWO CASES OF TRAUMATIC HYSTERIA.

This was the title of a paper by DR. HENRY HEX, of Albany. The first case had resulted from a railway collision, and the second from a severe fall in the street. In the first instance there were hysterical convulsions, temporary insanity, hemianesthesia, and paralysis of motion and sensation in one leg. Both cases had presented many symptoms typical of hysteria. Seclusion in a hospital, and vigorous and painful treatment were necessary before any improvement was manifested. The first patient had been cured, and the second was greatly improved. In the first case the cure did not take place for more than a year after substantial damages had been awarded. Indeed, both patients were awarded large damages; but the progress towards recovery was in no way modified by this fact. Simulation was carefully considered and excluded. The speaker said that the question as to the amount of money which was to form just compensation for an injury received, was always a difficult one to answer; and this was especially true when in regard to injury of the nervous system, whether organic or functional. In the case of organic nervous disease, such as cerebral tumor, myelitis, neuritis, etc., which might result from an injury, these lesions were always of such slow development that several years might elapse before the symptoms were pronounced, and therefore the injury to the nervous system was not fully manifested till long after the question of damages had been settled. The question was not less difficult in the case of those functional diseases of the nervous system re-

sulting from injury; and the difficulty in these cases arose partly from the danger of deception, because many of the symptoms were easily feigned, and the patient had great temptation for such feigning of symptoms, and partly from the great obscurity of the pathology of these diseases. These cases of functional nervous diseases which were described by Erichsen, under the name of spinal concussion or railway spine, were now generally regarded as of cerebral origin, and known by the name of traumatic neuroses. They depended, in their etiology, quite as much on the fright as on the physical injury. In conclusion, it was suggested that if any claim for damages was made on account of a functional nervous disease resulting from injury which was due to the negligence of a corporation or an individual, it would be wise if such corporation or individual were to offer to pay for the special hospital treatment of the patient in the hope of obtaining a rapid cure. In a considerable number of cases the offer might be accepted, and in the other cases the fact that the offer had been made would put the defendant in a better light before the jury, for no expert could deny that, had such a course of treatment been adopted, the patient would have stood a better chance of recovery. Furthermore, on deciding upon the amount of compensation, it should be remembered that a considerable number of these cases were easily and rapidly cured under proper treatment, especially after the question of damages had been definitely settled.

#### THE TREATMENT OF DETACHED RETINA.

DR. DAVID WEBSTER, of New York, read a paper on this subject. Detachment of the retina, he said, though neither as common nor as amenable to treatment as many other diseases of the eye, was still often enough seen to merit the attention of ophthalmologists. Over three hundred cases had been seen at the Manhattan Ear and Eye Hospital since it commenced work in 1869. The non-surgical treatment of this form of eye trouble had been by hypodermic injections of muriate of pilocarpine, in addition to the recumbent posture, atropine and bandaging. A very considerable proportion of recent cases treated in this way were improved, and a much larger proportion were cured, than had been by previous methods. As far back as 1850, Sichel resorted to what seemed to be a rational method of treatment, namely, surgical interference. There were two methods of doing this: one was to go in front of the sack and puncture it, in the hope that the subretinal fluid would escape into the vitreous chamber, and thus allow the retina to be reunited to the choroid; the other was to puncture the eyeball at the site of the detachment, and allow the subretinal fluid to escape externally. The former would seem to be the more rational operation theoretically; but the latter, he thought, was practically the more successful, and involved less danger to the eye. In March, 1889, he had done his first operation by sclero-puncture. Since that time he had performed the operation on a number of occasions. All of the eyes operated upon were improved more or less, though some of them only temporarily. In one case the result was highly satisfactory; the retina had become re-attached completely, and had remained so. The central vision was raised from 20-200 to 20-40, and the visual field was complete. The results in another case were almost perfect. In this the central vision was permanently raised from perception of light to 20-40.

DR. D. B. ST. JOHN ROOSA said he thought that Dr. Webster had rendered signal service to the public in reviving operative and therapeutic measures in this condition. At best, the prognosis was but bad; but that should not deter from an attempt at cure, and in a small contingent something might be accomplished. We were not sufficiently informed to enable us to scientifically attack the causes which lead up to the disease; and in the absence of any better knowledge on the subject, he thought that they were justified in taking Dr. Webster's view of the situation.

DR. H. D. NOYES said, that, while he did not wish to throw cold water upon the hopeful view which the author of the paper had taken, he thought that very little was to be expected in this disease, from operative or any other procedure. The best results were to be looked for from measures directed to the general health of the patient and a restoration of the healthful condition of the eye itself.

DR. WEBSTER, in reply to a request, detailed the steps of the operation. With the eye cocaineized, the patient was directed to turn the eyeball in that direction which would enable the operator to puncture at a point on the sclera as nearly as possible opposite the retinal detachment. The puncture was then made with a von Graefe's knife, the knife then being slightly turned to allow the escape of the subretinal fluid. A careful attempt was then made, with the knife still in position, to slightly wound the retina, in the hope of setting up some exudative process, and thus facilitating adhesion. The scleral wound was then closed with a couple of stitches, the eyes banded, and the patient kept quiet for a few days.

#### THE CAUSES OF ASTHENOPIA.

This was the subject treated of by Dr. D. B. ST. JOHN ROOSA. In speaking of asthenopia, he did not include those cases which were the inevitable result of certain diseases of the eyeball or of any part of it, but those cases which were congenital and where no appreciable eye lesions existed other than those of unequal development in the diameters of the eyeball. He denied the existence of an absolutely normal eye, that was to say, normal as to refraction, and asserted that the members of the human race were never born into the world with normal eyes, except in very rare instances. These congenital abnormalities were seen in the large percentage of hypermetropias, myopias and astigmatism, with which the ophthalmologist had to deal; such conditions being a cause and not an effect of the asthenopia, when it existed, though these abnormalities were frequently present without any asthenopia ever being complained of. Back of all the alleged causes of asthenopia lay the nerve exhaustion of the nineteenth century; it was essentially a disease of our time. As to the matter of muscular insufficiency, the speaker was convinced, but had been unable to satisfy all his friends, that to chase up the ocular muscles in the hope of affecting a cure for all cases of asthenopia was utterly useless. Honest investigation of the causes of this condition must be looked for among disorders of the nervous system.

DR. NOYES said the attitude taken by the last speaker, and by those who held similar views, reminded him of a story told of the late Bishop Wilberforce, who had in his household a domestic of the Romish religious persuasion. The bishop one day said to her, "Margaret, I suppose you think that your mistress and

I can never get to heaven?" "Oh, I do not say so: I think you will be saved on account of one thing."—"And what is that?" asked Wilberforce.—"Why, on account of your invincible ignorance."

The speaker had given the subject of asthenopia a constant study over a very long period. He wished to be understood that he was not one of those who saw in these cases no other cause than muscular insufficiency, the last speaker had denied the existence of such a thing as muscular asthenopia, and with that opinion he begged absolutely to differ. The speaker then referred to one hundred carefully selected cases in which treatment directed to the ocular muscles had cured or benefited the asthenopic symptoms. This treatment had either been by the proper adjustment of prisms or by operation. In cases where he had decided that tenotomy was indicated, his results had been all that could be desired.

(To be continued.)

#### MASSACHUSETTS MEDICAL SOCIETY.

COUNCILLORS' MEETING, FEBRUARY 4, 1891.

A stated meeting of the Councillors was held at the Medical Library, Boston, on Wednesday, 4th inst.

The meeting was called to order at 11 A.M., by the President, DR. AMOS H. JOHNSON. Ninety-one Councillors indicated their presence by signing the roll.

The following delegates to other State Medical Societies were appointed:—

Maine: Drs. C. G. Carleton, of Lawrence; F. H. Williams, of Boston. New Hampshire: Drs. S. B. Woodward, of Worcester; E. G. Cutter, of Leominster. Rhode Island: Drs. F. A. Howe, of Newburyport; F. S. Atwood, of Salem. Connecticut: Drs. F. H. Brown, of Boston; A. T. Cabot, of Boston. New Jersey: Drs. A. H. Nichols, of Boston; F. W. Chapin, of Springfield.

Committees were appointed:—

To Audit the Treasurer's Accounts: Drs. S. W. Driver, J. H. McCollom.

To Examine the By-Laws of District Societies: Drs. S. D. Presbrey, J. C. White, F. W. Chapin.

The Committee on Membership and Finances reported names of Fellows to be allowed to resign, to retire, to have dues remitted, and also to be dropped for non-payment of dues, and their recommendations were adopted.

Dr. H. E. Marion, of Brighton, was appointed a member of the Committee on Medical Diplomas in place of Dr. F. S. Watson, resigned.

In accordance with the recommendation of the Committee on the petition for a change in the boundary line between the Norfolk and Suffolk Districts it was voted that the petitioners have leave to withdraw.

The appointment of Dr. S. W. Abbott, of Wakefield, to fill the vacancy in the Committee on the Distribution of Diseases, caused by the death of Dr. W. Everett Smith, was confirmed.

Dr. F. Holyoke, of Holyoke, showed to the members of the Council a portrait of his great-great-grandfather, the late Dr. Edward Augustus Holyoke, of Salem—the first President of the Society—also a pocket medicine-case in use by him at the time of his decease.

The President presented obituary notices of Drs.

C. E. Spring, O. W. Doe, and A. F. Holt, Councillors deceased since the last meeting, and then addressed the Council as follows:

Upon the death of a member of this Society, ordinarily it is contrary to custom to take formal action in order to express our high esteem for his character and services. This fact makes it possible for us to bestow exceptional tributes when they are due. It also suggests that we should not neglect to confer the highest honor in our power upon those who have distinguished themselves, and our profession, by the preëminent value of their contributions to medical knowledge and practice.

The name Bigelow, upon the roll of those who have been members of this Society, is a greatly prized heritage. Dr. Jacob Bigelow was the treasurer of the Massachusetts Medical Society for the five years, from 1823 to 1828. He was its President, for the five years, from 1842 to 1847. As its orator, in 1835, he delivered that memorable address, on "Self-Limited Diseases," which marked the renaissance of medical practice. Dr. Henry J. Bigelow proved worthy to bear his father's honored name. Although, seemingly, he had less breadth and depth of classical learning, and less serious earnestness of character; his varied gifts, his originality and skill as a surgeon, his tact, clearness, and grace as an instructor, placed him conspicuously high in the esteem, nay, in the proud regard of all members of our profession. Thrice, namely, in 1861, 1862, and 1864, our Society honored itself by inviting him to preside as Anniversary Chairman, and in 1871 to deliver the Annual Address. It is unnecessary for me to particularize in order to illustrate to this Council the thoroughness, usefulness, and originality of his work.

Some of you will remember that during our Civil War, General McClellan visited the Massachusetts General Hospital. Few of us will forget the scene in the operating-room in the rotunda, when Dr. Bigelow introduced the popular General to the students then filling the seats, and called his attention to many interesting circumstances. Among them to the facts that the first operations under anesthesia from ether had been then performed, and that the sponge shown to him was the first upon which the ether had been administered. As the Professor, with his native elegance of form and bearing, brightened by his enthusiastic, stood side by side with the uniformed General, who had attracted to himself the honor and hopes of a nation, one could not but compare the service to mankind rendered by the two men, and in the wide-spread relief of suffering, and the rescue of thousands of lives through the brilliant far-reaching work of the Professor, find reason to accord him honors even greater than those won by the Commander-in-Chief of the Union armies.

There is an old proverb that "to lucky men good fortune will come even when they are asleep." But not thus came eminence and honor to Dr. Bigelow. True, he was born into the advantages arising from his father's ample means, his father's learning, and high social position, and his father's high professional reputation; but history shows that such circumstances by no means assure success. They tempt to a life of luxury, idleness, and the entertainments of literature and art, at the same time that they furnish a vantage-ground on which to commence scientific work. With such favoring helps a son may only rise to a tolerably

respectable standing and usefulness, which may then appear all the smaller in value from its contrast to the higher attainments of the father. According to the testimony of those who best knew him, Dr. Bigelow's eminence, like all real eminence, was the due reward of industry and hard work. At the beginning of his career he was armed cap-a-pie for the battle of life with weapons of finest temper, and with armor highly wrought, flexible and strong, but his achievements were won by the spirit and activity of the man bearing such equipments. Ambition, enthusiasm, perseverance, work, reinforced and made fruitful his genius. His versatile talents were actively employed, and the product of their combined power was the great quickness of apprehension, fertility in resources and facility and grace in manipulations, for which he was remarkable. The Massachusetts Medical Society honors itself in bringing a tribute of admiration of his work and gratitude for his services. In so doing we direct attention to a high standard of professional zeal and surgical skill, which to approximate involves most commendable industry. While to equal the rank to which a gifted nature, large opportunities, and spirited labors elevated Dr. Bigelow, must be the rare fortune of exceptionally endowed men. Yet great as were his genius and acquirements they do not so unapproachably lead the surgical profession to-day as in the generation when completeness of medical and surgical training was less common. His example is sure to be, nay, is even now emulously followed. His many pupils, who form all stages of professional life, look out upon the future of medical learning and practice, and we all, as we think of those taken from our number since last we met, may use the words of Tennyson:

"Men, my brothers, men the workers, ever reaping something new;  
That which they have done but earnest of the things that they shall do;  
Yet I doubt not through the ages one increasing purpose runs,  
And the thoughts of men are widened with the process of the sun.  
Knowledge comes, but wisdom lingers, and I linger on the shore,  
And the individual withers and the world is more and more."

DR. T. H. GAGE, of Worcester, said:

MR. PRESIDENT: I rise for the purpose of making a motion; but I trust it will not seem to my associates here presumptuous, if, before submitting it, I detain them for a single word suggested by the very impressive official announcement which has just been so appropriately made from the chair.

To the great body of Dr. Bigelow's pupils, and personal friends in the profession throughout the Commonwealth, his death was sudden and unexpected. Few such were prepared by any previous knowledge of his illness for the intelligence of his death, and the announcement when it came was to most a painful surprise. He had been more generally and favorably and perhaps familiarly known to the physicians and to the people of Massachusetts than any other medical gentleman of his time. Both the profession and the laity had recognized and appreciated his learning, his wisdom, and his skill, and had been accustomed to regard him as a consultant, in surgical cases of unusual gravity, perplexity, or doubt, whose opinions were entitled to the highest respect, and whose conclusions and decisions scarcely admitted of appeal. Educated and intelligent persons in all parts of the Commonwealth, and of every calling, and all professions, had regarded him with interest and admiration, not only as

an accomplished man of science, but as a citizen, whose eminent services in promoting the welfare and happiness of the people, by the alleviation of human suffering, had contributed to the honor and the glory of the State. His students, the young and the old, scattered in all the villages and towns, from the mountains to the sea, those who had enjoyed the teachings of his later and maturer years, and those whose privilege it had been to sit under his instructions when the glow and enthusiasm of youth and early manhood were upon him, had preserved faithfully in their hearts the spirit of loyalty to their great preceptor, sentiments of affectionate regard and respect for his person and his welfare, and an interest, which was almost filial in its nature, in the honors and the fame that had come to him. Thus when the painful and unlooked for intelligence was flashed along the wires that Dr. Bigelow was dead, the sensation produced was widespread, and profound. The hearts of those who had known and admired him, and of those who had been accustomed to turn to him in times of emergency for assistance and advice, were moved, as they would be rarely moved except in the presence of some general and great calamity. And I do not fear that I shall lay myself open to the charge of exaggeration if I say that, as the melancholy tidings passed rapidly from one to another, over the State, the spontaneous and kindly expressions of sentiment and appreciation with which they were accompanied, all unpremeditated and impromptu as they were, constituted in themselves an appropriate and a beautiful tribute to the services and the character of the distinguished person whose unexpected removal had called them forth.

But, as the first and more immediate impressions produced by the great shock passed away, these informal and desultory expressions of sentiment and feeling, to which I have alluded, gave place, as befitted the subject, to more studied, dignified, and carefully considered utterances. The sad event was made, with great propriety, in various medical organizations, learned bodies, and public institutions, with which Dr. Bigelow had been connected, an occasion of special, and studiously prepared commemorative action. Very distinguished members of the medical profession, and eminent civilians, who had known him all his life, and some whose good fortune it had been to share his acquaintance within the charmed circle of his intimate friends and associates; thus had opportunity to bear appreciative and eloquent testimony to the great qualities of character, and the marvellous skill he had so conspicuously displayed. And the strong and salient features of both were faithfully and lovingly delineated.

But, Mr. President, it remains for the Councillors of the Massachusetts Medical Society to take some action; and, under the rules fixing the times of holding their meetings, the present occasion affords them their first opportunity. That it will be the unanimous wish of those who are present to avail themselves of it, and to improve it, by preparing for their records some suitable memorial of their late distinguished associate and friend, may be, I presume, taken for granted; and to facilitate such a purpose I move you, sir, that a committee of three be appointed by the President to prepare and report a form of action, expressive, in their judgment, of the sense of the Councillors upon this occasion, and suitable, if adopted, to be entered upon the record of this day's proceedings.

The motion was seconded with remarks by Dr. Z. B. ADAMS, of Framingham, and thereupon adopted.

The President appointed Drs. Gage, Adams and Draper as a committee, who presented the following memorial, which was unanimously adopted:—

The Councillors of the Massachusetts Medical Society receive with the deepest sorrow the official announcement of the death of Dr. Henry Jacob Bigelow, and avail themselves of the earliest opportunity to place upon their records an expression of their great respect for his character, and their high appreciation of the services rendered by him to the Society, which is here represented, and to the medical profession.

That Dr. Bigelow was one of the most accomplished surgeons and eminent teachers of his time is the unanimous verdict of his contemporaries; and, that his relative place in history will be the same, seems equally assured. The great practical achievements, with which his name has become imperishably associated, have in them permanent and enduring qualities, and will bear his fame to future generations. So long as, and wherever in all the wide world, a human sufferer in the hour of sorest need experiences the merciful alleviations of anaesthesia, or the surgeon approaches the management of vesical calculus or luxation of the hip-joint with the confidence and courage born of the new and better methods, so long and so universally will the name of this distinguished surgeon and great benefactor of the race be remembered with gratitude and spoken with admiration.

Dr. Bigelow's long and useful connection with this body is recalled with most agreeable associations. His participations in its proceedings have always influenced results, and contributed to the general welfare. No Fellow of the parent Society has been more faithful as a Councillor than he.

Of gracious, dignified, and noble presence; wise, witty, sententious, and direct of speech; eloquent; courageous in debate, yet courteous to opponents; the memory of his service here will be an enduring pleasure.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, December 22, 1890, DR. W. L. RICHARDSON in the chair.

DR. F. H. HOOPER demonstrated the modern methods of

#### TRANS-ILLUMINATION OF THE AIR-CAVITIES OF THE HEAD AND OF THE LARYNX.

DR. F. I. KNIGHT: I certainly have nothing to say except in commendation of the introduction of this method, particularly for the examination of the nasal sinuses. When I was in Breslau a good many years ago, Voltolini, among other things, showed me the trans-illumination of the larynx with the sun's rays, saying: "You will never do this again. You will never practise this. People come and see my good operations and go home and never make use of them." And that was true. I have seldom used it except to show it to students as a curiosity. It has been tried more or less in different fields of medicine for the last twelve or fifteen years, in the stomach, etc., as we all know. This application of it to the sinuses of the nose prom-

ises to be of a good deal of practical value. The differential diagnosis in this region is very difficult, and anything which is going to give aid in getting at the physical condition of these parts is going to be of real service, and the method is going to stay as a practical method, and I think that can be said of this examination of the accessory cavities of the nose as distinguished from the examination of the larynx. I do not believe much practical use is going to be made of it in the larynx. As to the merit of the discovery of trans-illumination, I think the gentleman who first put the candle behind a hydrocele might claim the honor.

Dr. LANGMAD: I have never had any practical experience with this method, and I think Dr. Hooper has told the whole story with regard to it.

When I was in Paris twenty-five years ago I was invited, with several other gentlemen, to witness an illumination of the larynx, cesophagus and stomach. The experiment consisted in the introduction of a platinum wire isolated by a box-wood carrier. The carrier immediately burned out, however, and the patient suffered injury in consequence.

This method may be of the very greatest importance, especially with regard to diseases of the antrum, and particularly with regard to dropsy or the presence of fluid in the antrum. I must say that in reading of the frequency of disease of the antrum, in which the causes are supposed to be an extension of a rhinitis into the antrum, I have been astonished that I have never seen more of them. I have seen comparatively few in hospital or private practice. Almost all the cases I have seen have arisen from the common causes; from some trouble with the first or second molar tooth. I suppose the reason that we do not see so many of the diseases of the antrum as they see in Europe is because our dentists are so much better informed in regard to these diseases and are constantly on the watch for them. I suppose we should be astonished if we knew how many cases of disease of the antrum arising from the teeth had occurred in this city. The dentist extracts the molar, drills through, secures drainage, and says nothing about it. The books speak of disease of the antrum as an extension of a rhinitis as being very common, but in my experience it has not been so.

#### ANATOMICAL SPECIMENS.

Dr. JOHN HOMANS showed specimens of Fibroid Tumor of the Uterus, Cancer of the Uterus, and Malignant Adenoma of the Uterus, removed by abdominal section, by vaginal hysterectomy and by a combined method of abdominal and vaginal section.<sup>1</sup>

Dr. J. W. FARLOW showed a Fibro-Sarcoma with a small pedicle, which he had removed by a snare from the anterior part of the septum of the nose; also a large, posterior Hypertrophy of an Inferior Turbinate Bone which showed very plainly the mulberry-like character of the growth; also a large mass of Adenoid Growth, removed from a child six years old, together with a cast of the child's upper jaw, showing the narrow, high arch and how useless it would be to try to straighten the teeth or spread the jaw until the growths were removed; also a Parasitic Growth removed from the tongue of a man of sixty years, and the culture of the fungus on gelatine. This case is to be reported in full at a later date.

Dr. J. C. WHITE spoke to the Society on

#### LEPROSY, WITH LANTERN ILLUSTRATIONS.

See page 184 of the Journal.

#### JOHNS HOPKINS MEDICAL SOCIETY.

At a meeting of the Johns Hopkins Medical Society held in Baltimore on February 2, 1891.

Dr. MORISON presented a case of

#### LICHEN RUBRA TREATED BY KOCH'S METHOD.

The patient, a woman twenty-four years old, had been suffering from the present attack for three years. When sixteen years old the disease first appeared, and during three years resisted all treatment. At the time of entrance to the hospital she was much emaciated, very anæmic, her skin was shrivelled like parchment, and her legs so drawn up that she could not extend them. The diagnosis at the time was difficult; there were appearances of eczema, psoriasis and lichen rubra for some time, which gradually became characteristic of lichen only.

The patient had been dosed with arsenic to toxicity, and a long list of tonics had been used without the least benefit. At this extremity Dr. Morison injected three milligrammes of the Koch lymph. An intense reaction followed, and some improvement. Five injections were made, none exceeding five milligrammes; and when presented before the Society, the patient's general condition was greatly improved. No typical lichen patches could be seen, and this was thought to prove another of the marvelous cures by the lymph.

Dr. OSLER reported a singular case of

#### MULTIPLE CYSTICERCII OR CESTO-TUBERCULOSIS.

The patient was an Irishman, well built and muscular. On entering the hospital he had suffered with severe pains in arms and legs, and with muscular stiffness, inability to walk, marked weakness, congestion of the hands. The case seemed like one of alcoholic neuritis. Numerous painful nodules were felt beneath the skin in various parts of his body, too numerous for a diagnosis of Paget's subcutaneous painful tumors.

Dr. LA FLEUR suggested that it was a case of cysticerci; and on microscopic examination this proved to be the origin of the tumors. The man had evidently eaten a portion of a segment of a tape-worm, digested its ova, set free the six-hooked embryo, which had migrated in the blood until arrested, and then developed in the muscular and cellular tissues. About two dozen could be felt — the size of peas — painful on pressure and doubtless the cause of the muscular stiffness and swelling of the hands. Their size depends on the pressure of the surrounding tissues, so that in the peritoneum or brain they may grow to a great size. They are more common in the brain than elsewhere, and much more serious, causing diabetes and a great variety of diseases.

Dr. OSLER had experimented on pigs, feeding them with the ova of *tania mediceo-canellata*. These were borne with great impunity, and in three months could be found in the pig's muscles, under the tongue, and in the cellular tissue. After a certain time the segments calcify.

The possibility of auto-infection is interesting. There is ample room for the supposition that the ova might migrate from the bowel to the stomach and there be digested for circulation.

Dr. HOWARD KELLY reported

#### A CASE OF CÆSARIAN SECTION.

The previous history was of two pregnancies terminated at term with exceedingly difficult extraction of

the child after craniotomy. The pelvis was flattened and rachitic. Diagonal conjugate, nine cubic millimetres; conjugata vera, seven-eighths cubic millimetres; occipito mental diameter of child, fourteen cubic millimetres.

When seen at the thirty-sixth week of pregnancy, the labor pains were beginning. The head was presenting transversely but not engaged in the superior strait. A Caesarian section was thought advisable. The patient was prepared, and an incision, sixteen cubic millimetres long, above and below the umbilicus, was made at 4.17 p. m. At 4.19 the child was delivered by the breech, thus avoiding all trouble with the shoulders, and after-coming head. At 4.21 the uterus was sewed with silk; and in a few minutes more the patient was comfortable in bed. The baby was strong and well, weighed 3,200 grammes. Patient nursed the baby; had less than the usual number of after-pains; sat up on the twelfth day as after a normal labor.

DR. LA FLEUR reported several cases

#### OF HEPATIC ABSCESS.

Patients entered the hospital emaciated; with abdominal tenderness, cough, and viscid, brownish, copious expectoration. Sputum and stools were swarming with amœbæ; liver dulness was greatly increased.

At the autopsy of one case the peritoneum was inflamed; amœbæ were active in the fluid; liver extended to the umbilicus. The right lower lobe of the lung was consolidated and adherent to the diaphragm; in this was a large abscess, seven by six cubic millimetres, communicating through a perforation in the diaphragm with the liver abscess. The amœbæ are usually confined to the lymph-vessels and to the veins. They present the appearance of fresh-water amœbæ without the characteristic contractile vesicle.

These patients all came from Sparrow's Point, where they had been drinking the same well-water; and amœbæ had been found alive in the stools and sputum of twelve cases, all bearing the same resemblance to fresh-water amœbæ.

**MULTIPLE SKIN-GRAFTING.** — A contemporary thus describes the manner in which a member of a society had his skin replenished: "Three detachments of Sir Knights, each plumed and bearing in his right hip pocket a razor of Damascus steel, marched on Sunday to the baths adjoining the operating room of the hospital. One by one they rapidly disrobed themselves and with their unsheathed razor plunged into the foaming torrent of soap, water and steam. Emerging into the operating room thus purified, as to the razor and as to the skin, a left assistant grasped the razor and stripped from the quivering flesh a thin film of skin. The bleeding Sir Knight, groaning with the unaccustomed pain, rushed madly on to the open flask of liquor prepared for his refreshment, while the mutilating assistant passed the torn fragment of skin to the surgeon who placed it on the naked flesh of a brother Sir Knight rudely flayed in his battle against that arch enemy, Sarcina. Thus only when one hundred and thirty Sir Knights had been bathed, skinned and refreshed was the gaping wound satisfied."

THE BOSTON

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 19, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

**SUBSCRIPTION TERMS:** \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

### ANNUAL REPORTS OF THE PRESIDENT AND TREASURER OF HARVARD COLLEGE.

WE take from these annual reports (1889-90) the following items of interest to our readers:

The whole number of students in attendance in the Medical School of the University during the year was 304; during the first term, 290; during the second term, 287. Of these, 156 had literary or scientific degrees. There were 75 applicants for the degree of Doctor of Medicine in the three-years' course, of whom twenty-two were rejected. There were 15 applicants for the degree of Doctor of Medicine in the four-years' course, of whom two were rejected; four of the students received the degree *cum laude*. The fourth class was composed of 23 students.

The Dean of the Medical School in his report, suggests the importance to the School, for increasing the facilities for clinical instruction, of a hospital under the control of the Faculty, and states that no worthier object can be suggested to friends of medical education than the establishment and endowment of such an institution. Both the President of the University in his report, and the Dean of the School in his report, recommend the endowment of the Department of Bacteriology, in order to enable the head of that department to devote his whole time to the work of instruction and research, and to secure the assistance without which research is very slow and laborious. We have already given a detailed account of the arrangement and purposes of the new Sears Laboratory for Bacteriology and Pathology.<sup>1</sup> A more complete equipment for the Department of Histology and Embryology is desired.

In the direction of original research it is stated that, in the Anatomical Department material has been secured for the investigation of the relations between the shape of the bones and the figure of the individual, and the Professor in this department has published observations on the breast bone as an index of age, sex and height. The Professor of Embryology has published

<sup>1</sup> Journal, January 29, 1891.

lished a number of papers bearing upon studies in his special department. In the Chemical Department Professor Wood has been continuing investigations as to the elimination of arsenic in cases of chronic poisoning by that substance, and has also been studying the use of various menstrua for the restoration of dried blood stains in connection with medico-legal work. Dr. J. J. Putnam has continued his inquiries into the frequency with which lead and arsenic are found in the urine. In the Departments for Pathology and Bacteriology studies have been made of the diseases among the animals slaughtered at the Brighton abattoir; on cutaneous tuberculosis; as to the infectious nature of the milk of tuberculous cows; as to the presence and virulence of the bacilli of tuberculosis in sputa dried and kept for three years; an epidemic of hog cholera has been investigated; Dr. S. H. Martin has studied the biological characteristics of vaccinia in calves, and reports that he has obtained a mixed culture which produced vaccinia on inoculation—an interesting and possibly very important statement.

The Faculty of the Dental School resolved in 1889–90 to establish a three-years' graded course, beginning in September, 1891, and they have given public notice to that effect. Except that students will still be admitted to advanced standing on examination, all candidates for the degree will thereafter be required to pass three years in the School. Certificates of study in the office of a private practitioner will no longer be accepted. This action of the Faculty will add materially to the cost of the dental degree, and may temporarily diminish the number of students in the School; but it will raise the standard of the degree and add to its value.

The Veterinary School and Hospital are reported to have had a prosperous year—the most prosperous of the seven years of their existence. The hospital, by receiving only paying patients, was able to meet its own expenses, and the excess of the expenditures on the school over the receipts from the school.

#### CAMPHORIC ACID AND TELLURATE OF SODA IN NIGHT SWEATS. TWO NEW ANIDROTIC MEDICAMENTS.

CAMPHORIC acid, which was discovered in 1675 by Lémery, has very recently been made the subject of clinical studies by Leu, in *Centralblatt für Klin. Med.*, and by Dreesmann, in an inaugural thesis. It is obtained by heating camphor with ten times its weight of nitric acid; it presents itself in the form of little scales or colorless needles, which are transparent and bitter to the taste, melting at 70° C., and dissolving freely in alcohol, ether and essential oils, somewhat sparingly in boiling water, and being scarcely at all soluble in cold water.

Leu has remarked that, when camphoric acid is administered to tuberculous subjects who are subject to night sweats, in the dose of thirty grains, it pro-

duces a marked anidrotic effect several hours after its absorption; sometimes the suppression of the sweats does not come on till the next day, and the effect of one dose may last several days. The same good results may be obtained from the use of alcoholic lotions of camphoric acid, the lotions being freely applied to parts where the sweating is localized. Leu affirms that no ill effects have ever followed the internal or external use of this remedy. A soporific action sometimes follows the ingestion of a thirty-grain dose.

Camphoric acid was tried in thirteen bad cases of night sweats; in sixty per cent. of these cases the sweats were suppressed, in twenty-two per cent. they were diminished, and in eighteen per cent. only the remedy failed. Dreesmann has found this anidrotic effect of camphoric acid only in tuberculous cases; if the sweats are due to any other cause, the remedy is inefficacious. His experiments have shown that the sweating, which is provoked by pilocarpine, is not influenced by camphoric acid; hence he concludes that this medicament does not act by the intermediation of the central nervous system, but by destroying the soluble products of the tubercle bacillus, which are the direct cause of the profuse sweats symptomatic of the stage of pulmonary ulceration.

Combemale, in the *Bulletin Général de Thérapeutique*, January 15, 1891, has published the results of a series of clinical trials of camphoric acid, and concludes:

(1) That camphoric acid has a certain action on the night sweats of the tuberculous; it very often arrests them, frequently diminishes them, and is very rarely without effect.

(2) These effects follow doses of thirty grains, once a day, at 7 o'clock, p. m.

(3) No disagreeable or harmful after-effect has followed the usage of camphoric acid.

Combemale agrees with Leu as to the necessity of limiting the therapeutic application of camphoric acid to the night sweats of the tuberculous, and affirms that in his experience it has a very uncertain action in advanced cases of pulmonary phthisis with large cavities. It is in recent cases where the purulent surfaces are small, where the tubercles are still crude, or are just beginning to soften, that it does the most good, and here the remedy is almost infallible in its action.

Another new anidrotic has been announced—tellurate of soda. It is an oxygenated salt of tellurium, and is obtained by heating a mixture of tellurium or its binoxide, with soda or nitrate of soda. It is the normal tellurate ( $\text{Na}_2\text{TeO}_4 + 5\text{H}_2\text{O}$ ) which is employed. This salt is soluble in water and in alcohol, and presents itself after evaporation in the form of a gummy mass or whitish amorphous powder.

Neusser, in *Wiener Klin. Wochenschrift*, 1890, was the first to recommend the employment of tellurate of soda in night sweats. He gave pills of one-third of a grain each, and found one of these pills *per diem* sufficient to restrain the most obstinate night sweats of the phthisical. The ingestion of the remedy is followed

by a garlic-smell of the breath, but no injurious effects have been noticed.

Combemale (*loc. cit.*) has made trials of tellurate of soda in phthisical cases; he has obtained favorable results similar to those recorded by Neusser in nocturnal diaphoresis. He gave small doses, amounting to from half a grain to a grain daily, dissolved in a little julep. He has found that the remedy succeeds in the advanced stages of tuberculosis better than camphoric acid. The tellurate of soda acts equally well in restraining the night sweats of rheumatism, typhoid fever, and other prostrating affections. Both remedies are supposed to produce an antiseptic action, destructive of the soluble products of the microbes!

#### THE VITAL STATISTICS OF MASSACHUSETTS FOR THE YEAR 1889.<sup>1</sup>

In a population estimated to be 2,175,153, the births in Massachusetts in 1889 were 26.24 to each 1,000 persons living, as compared with 25.35 for the decade ending in 1889; the marriages were 9.37, as compared with an average of 9.07 for the thirty-five years ending in 1885; the deaths 19.21, the least in the decade, except 18.62 for 1888, and .42 less than the ten years' average. The population by census has increased from 994,514 in 1850 to 2,233,407 in 1890, or 2.53 per cent. in the last ten years.

The birth-rates and marriage-rates are much higher in the cities than in the towns, and generally indicate a gradual admixture of the native and foreign-born. The average age of first marriages has increased from 1871, for men, from 26.3 to 26.9; and for women, from 23.5 to 24.5. The divorces have increased in twenty years from 1 in 38.8 marriages to 1 in 26.9, the average being 1 in 29.1, the total number having about doubled (379-756), while the population has increased 49 per cent. in the same time. Of the 11,140 divorces granted in twenty years, 69.1 per cent. were on complaint of the wife. For adultery 1,584 were granted to women, 1,411 to men; for desertion 3,230 to women, 1,854 to men; for intoxication, 1,196 to women, 147 to men; for cruelty and abusive treatment, 1,390 to women, 18 to men; for neglect to provide, 234 to women, none to men. In 1889, the cases not contested were 89.1 per cent. of all; the percentage of successful applications for divorce was 98.2.

The public health for the year was above the average. Diphtheria, steadily increasing for five years, reached in 1889, including croup, 2,214 deaths, as compared with 1,523 in 1885. Scarlet fever was much less fatal, 185 deaths, and in the previous year, 504. Diarrhoeal diseases caused a lower death-rate than in 1888, or 3,835 deaths. The mortality from pneumonia was nearly eight per cent. less; and from bronchitis

somewhat less. Typhoid fever caused slightly, and measles considerably, less fatality.

The violent deaths were 973, of which 175 were suicides, 12 homicide, 350 drowned and lost at sea, 52 from poison, and 241 from railroad accidents. There were only six deaths from small-pox. With slight variations from year to year, the mortality from typhoid fever has been about stationary for the past ten years, the improvement from better sanitary conditions having virtually ceased; its death-rate in Suffolk County is less than in any other part of the State except the small islands.

The reported death-rate from pulmonary consumption has decreased from 34.3 per 10,000 in 1870 to 25.7 in 1889, and during the same period, from dropsy, from 17.9 to 3.8. In the same time the rate from brain diseases has increased from 14.35 to nearly 20; from cancer, from 3.5 to 6.1; from kidney diseases, from 10.5 to 30.1; from heart diseases, from 6.60 to 15.08. A great part of these changes come, of course, from better diagnosis and improved registration; but still the figures are, to an extent, significant both of the change in the character of our population and in the habits of living. The deaths recorded from malaria were 77, or more than twice as many as in the previous year. Of the 54 deaths from syphilis, 83.3 per cent. were in Suffolk and Middlesex Counties.

The Medical Examiners' returns, based upon 1,654 deaths from sudden, violent and suspicious causes, indicate an immense improvement upon the old coroner system, and at decreased cost.

The report is up to its usual high standard of excellence, and will well repay careful study.

#### MEDICAL NOTES.

**TO REGULATE PHYSICIANS' FEES.**—There are an unusually large number of bills before the different state legislatures this year to regulate in one way or another the practice of medicine. Georgia tried to prevent its doctors from getting drunk, and now Missouri is to consider the advisability of limiting the fee for a visit between 8 A. M. and 9 P. M. to one dollar, and for an office prescription to fifty cents.

**AN AID FOR THE FIELD-SURGEON.**—Every French soldier will receive shortly from the ministry of war a package containing antiseptic cotton, bandages and two safety needles. He will carry the package with him into battle, so that if wounded, the materials for dressing his injuries will be at hand for the field-surgeon.

**PYOKTANIN STAINS,** says Merck's *Bulletin*, are readily removed from the operator's hands by washing with spiritus saponatus, or with a ten per cent. solution of castile soap in alcohol, or with liquor soda chlorata. Pyoktanin pencils, when broken, are mended by simply wetting the severed surfaces with water, and pressing them together gently; when dry they will cohere.

<sup>1</sup> Forty-eighth Report to the Legislature of Massachusetts, relating to the Registry and Return of Births, Marriages, and Deaths in the Commonwealth for the year ending December 31, 1889, together with the Reports relating to the Returns of Libels for Divorce and to the Returns of Death investigated by the Medical Examiners for the year 1889. Prepared by the Secretary of the Commonwealth, with editorial remarks by Samuel W. Abbott, M.D. Boston: Wright & Potter Printing Co., State Printers, 18 Post Office Square, 1890.

**PROFESSOR KOCH'S METHOD.**—Dr. Von Gossler, Minister of Medical Affairs, etc., has requested the heads of the clinics, policlinics, and pathological institutions of the Prussian universities to report their experiences of Koch's method. The first collection of reports will be published soon by Springer of Berlin. Professor Brieger is to be head of the clinical department in Koch's new institute, and it is likely that Dr. Behring, whose valuable researches on the subject of immunity attracted much attention lately, will be head of the experimental department.

**ADULTERATION OF PHENACETIN.**—More than two years ago the likelihood of the adulteration of phenacetin with antifebrin was pointed out by Schwarz, Schröder, and Hirschsohn, owing to their great resemblance in physical and chemical respects, and to the difference in the commercial values, phenacetin being at that time about fifteen times the price of antifebrin. All three observers indicated tests by which such adulteration could be detected but in spite of their very timely warning a case in Elberfeld exhibiting toxic symptoms has recently occurred, and on investigation it was found that the powder supplied, when phenacetin had been ordered, consisted of equal parts of phenacetin and antifebrin or acetanilide.

**HOSPITAL FOR VIENNA STUDENTS.**—A hospital for sick students of all nationalities was recently opened at Vienna by the Emperor. Professor Schröter delivered an address, in the name of the Society for the Care of Sick Students, in which he expressed the satisfaction felt by the Society in having at last, after thirty years of work, a home of its own for the reception of students overtaken by illness. The hospital has accommodation for thirty-seven patients, eight beds being set apart for surgical cases, and nine, in a separate block, for infectious cases. Dr. Redtenbacher will have charge of the medical and Professor Von Dittel of the surgical section; dermatological cases will be under the care of Professor Lang.

**DELAWARE JUSTICE.**—The pillory and whipping-post are still in use for public punishments in Delaware. A daily paper relates that during a cold rain, two men stood in the pillory for an hour—one an old, gray-haired man, who had pleaded guilty to a petty forgery, and the other a negro, who had been convicted of burglary and larceny. When taken from the pillory the men were numb and they could scarcely move their hands and necks. The negro, who then fastened to the post and twenty lashes were laid across his bare back. Then came the other ten victims, each in turn receiving five lashes from the Sheriff. The total value of goods stolen by these ten thieves was \$56. Each of the victims will now undergo an imprisonment of one or two months.

**WISCONSIN MEDICAL PRACTICE LAW.**—The Wisconsin Legislature has recently passed an act creating three Boards of Medical Examiners, representing the Western State Medical Society, the Homoeopathic Medical Society, and the Lohetic Medical Society of the State respectively, each board to consist of three

members, appointed by the governor from a list of candidates submitted by the respective societies. The supervisor of medical examinations, who shall not be a practising physician, is to be appointed by the governor and will hold office until his successor shall be appointed. The several boards must submit to the supervisor of medical examinations, lists of questions for examination in the usual branches, and from these lists the supervisor will select at random the questions for each examination and present the same to the candidates. Each candidate must present to all three of the boards satisfactory evidence of good moral character, that he is more than twenty-one years of age, that he has obtained a competent common-school education, that he has studied medicine three years including two years in some legally incorporated medical school, and that he holds a legitimate diploma conferring the degree of Doctor of Medicine, or a diploma or license conferring the full right to practise all branches of medicine and surgery in some foreign country. No one, not previously entitled to practise medicine under the existing laws of the State, will be permitted to practise after the first day of July, 1891, unless he has received a license from one of the legally constituted boards of medical examiners. Any candidate who fails at one examination will be allowed to appear before the board again after an interval of six months.

#### BOSTON AND NEW ENGLAND.

**TUBERCULOSIS IN CATTLE.**—A resolve was reported during the week by the Committee on Public Health, of the Massachusetts Legislature, providing for an investigation by the State Board of Health into the dangers to human life and health arising from tuberculosis in the food products of cattle, with authority to expend not exceeding \$15,000.

**LEGISLATIVE HEARINGS.**—Before the Committee on Public Health of the Massachusetts legislature during the week, the hearing on the prevention of pollution of sources of water-supply was continued. This order was aimed at the pollution of the Merrimac River at Lawrence and Lowell, as these cities under the present law are exempted from any direction on the part of the State as to the pollution of the river. The mill and factory representatives were present in large numbers in opposition. Dr. Leslie, of Amesbury, who presented the order, was the only person to appear before the Committee in favor of some legislation to purify the river. There are twenty-six sewer openings into the canals and river at the city of Lowell; all its sewerage is discharged into the river. The only water furnished the mill operatives to drink, is drawn from the river and canals.

A hearing concerning the transfer to local boards of health from the district police of the sanitary provisions and ventilation in public buildings and schools was continued, a sharp discussion being developed between the advocates of the present system and the reformers.

A hearing concerning the regulation of the practice of medicine by requiring the registration of degrees was held. A circular was distributed reflecting upon the Committee. The Committee was inclined to look upon the paper as contempt, and the hearing was brought to an abrupt close.

**THE RHODE ISLAND HOSPITAL.**—The twenty-seventh annual report of the trustees shows that during the year ending September 30, 1890, 1,089 patients were admitted, a gain of 187 over the previous year. The average number of patients at one time in the hospital was 83 and the average stay was 28 days. The number of new cases in the out-patient departments was 4,733. But once before since the hospital was opened has there been an excess of receipts over disbursements. By the gift of \$22,000 from Mr. T. P. I. Goddard, a new out-patient building will soon be completed.

#### NEW YORK.

**SOCIETY OF MEDICAL JURISPRUDENCE.**—At a meeting of the Society of Medical Jurisprudence held February 9th, Dr. Carlos F. Macdonald, President of the State Commission in Lunacy, read a paper on "Recent Legislation for the Insane in the State of New York," in which he described the reforms inaugurated under the laws establishing the State Commission and State care for the insane poor.

**DEATH OF DR. GEORGE R. CUTTER.**—Dr. George R. Cutter, an eminent eye specialist, identified both with New York and Brooklyn, died of pneumonia at his home in the latter city, February 11th. He graduated from the College of Physicians and Surgeons, New York, in 1861, and was fifty years old at the time of his death. Dr. Cutter was also a linguist of unusual attainments, and for many years did a large amount of work in the way of medical translation.

#### Miscellany.

#### THE DISSEMINATION OF TUBERCLE UNDER KOCH'S TREATMENT.

An observation which, if confirmed by other observers, will make a most serious impression on the opinion of the profession as to the safety of Professor Koch's treatment, has been published by Dr. Victor Liebmann, of Trieste.<sup>1</sup> The communication, it is expressly stated, is only a preliminary one, but it is of such importance that it is desirable that all those who are working with the fluid should make early investigations as to its correctness.

The important and suggestive statements made by Professor Virchow upon the possibility of the use of Koch's remedy being the means for the dissemination of tubercle throughout the body by the liberation of bacilli from a localized focus, seem to receive some confirmation from the discovery by Dr. Liebmann of tubercle bacilli in the blood of patients under this treatment. He states very distinctly that though control phthisical patients who had not been treated with

the Koch fluid were found to have in their blood no tubercle bacilli, those patients who had received one or more injections of the fluid were no longer in the same condition, as tubercle bacilli, not in large numbers certainly, but still in sufficient numbers to be pretty easily demonstrable, were circulating in the blood stream.

The method employed was to carefully disinfect by hydrochloric acid and alcohol the cover-glasses, etc., employed, and to take a drop of blood from the finger, previously thoroughly cleansed with pure alcohol and ether, and the needle also having been previously heated to redness. The preparations were placed in warm carbol-fuchsin for half an hour, then washed in distilled water, stained for one minute in a modified Gabber's solution, and examined in water.

Nine cases are given; all the patients reacted markedly to small doses; and bacilli, sometimes granular or broken, were to be found in the blood on the evening of the day of the injection or the next day, but they disappeared if the injection was not repeated.

The importance of this fact will not be overlooked. It bears out in a most remarkable manner Professor Virchow's observation that the bacilli "appeared to be mobilized," and to be much more readily transported from the diseased tissue to the circulating fluids.

Already these investigations have been repeated by Dr. Ewald at the Augusta Hospital, the preparations being heated to 110° C., and the blood taken during and after the fever, but without, in any case, confirming Dr. Liebmann's results.

#### RESORCIN IN SEPTIC POISONING.

ANDEER<sup>1</sup> has repeatedly called attention to the value of resorcin in cases of septic infection from post-mortem examinations. In not a single case has he failed to get great benefit from its use. In the case last reported there was already superficial and deep lymphangitis, great swelling, pain and discoloration of the arm, and swelling of the axillary glands. A large number of antiseptics had been tried without effect, but with the application of resorcin pain disappeared in a few hours, and the patient made a rapid recovery.

#### OPERATION FOR GRAVES'S DISEASE.

DR. LENCKE,<sup>2</sup> of Hamburg, discusses the subject of exophthalmic goitre with special reference to its treatment. He claims that as the treatment of this condition by medicine is remarkable for nothing so much as its inefficacy, if the surgeon can offer even a chance of relief his interference is justifiable, and he relates two cases in which surgical interference seems to have had the best results. The first patient was a lad of seventeen, who had the classical symptoms of the disease—rapid heart, palpitation, prominence of the eyes, and goitre. He came under treatment on account of a sudden access of the swelling, which by the pressure it exerted produced great distress with extreme cyanosis. The heart was rapid and irregular, no rest or sleep could be obtained, and the patient was in

<sup>1</sup> Virchow's Archiv, Bd. 122.

<sup>2</sup> Deutsche Medicin. Wochenschr., January 10th, and Lancet, January 17th.

<sup>1</sup> Berliner Klin. Woch., No. 1, 1891.

imminent danger of asphyxia. Tracheotomy was performed, and a week later one-half of the tumor was extirpated. The operation was accompanied by much hemorrhage, which, however, stopped spontaneously, and recovery was uninterrupted. The symptoms rapidly vanished, the exophthalmos disappearing, and the heart becoming quiet and regular in action. The improvement was maintained until the time at which the paper was written. Operation was undertaken in the second case, which had long been under observation, because of the good result in the first. The patient in this case was older, the symptoms were similar, and the operation was the same. The improvement was also very marked, and the patient four months ago was able to resume his occupation. It is yet too early to estimate the full value of the procedure adopted, as regards cure of the disease; but if relief can be afforded in other cases as great as was apparently obtained in those just related, a strong case will have been made out for the surgical treatment of this distressing malady.

### THE REGULATION OF PROSTITUTION.

This is a subject which has been very widely discussed and written upon in Europe during the last few months. The French have taken it up in connection with the question of the depopulation of France. At the International Medical Congress Dr. Thiry,<sup>1</sup> of Brussels, read a paper on this subject, in which he states that prostitution, whether desirable or not, is a necessary evil; and that, if it were possible to suppress it, society would be afflicted by libertinism. Inspection is the sole way to protect prostitutes and those that use them from disease. In certain countries it is ignored, on the fallacious theory that it antagonizes liberty and the dignity of women. Another error is to regard prostitution as a crime. He considered that the regulation of prostitution is necessary to restrain the propagation of venereal and syphilitic diseases. Prostitution that attracts attention by the frequenting of streets, being the most powerful cause of propagating venereal diseases, should be forbidden, and it should be confined to registered houses, with frequent sanitary visits.

Dr. Kaposi said that in Vienna each prostitute receives a book containing a description and photograph of herself, and a copy of the laws relating to prostitution. No one under sixteen can be registered, no persons afflicted with organic or constitutional disease. Sanitary examinations are made twice a week, all diseased women are put into hospitals, primary syphilitic cases are quarantined for three months, and kept under treatment for two years. Claudestine prostitutes are treated in the same way by their own physicians.

Dr. Nesser had examined 572 prostitutes in Breslau, and found the gonococcus in 216 patients.

Dr. Felix of Bucharest, Dr. Drysdale of London, Dr. Hemzinger of Groningen, and Dr. Crocq of Brussels, up to Thiry's conclusions, particularly the limitation of prostitution to a few public houses. Felix held that in the future we should instruct, without a model, the pupils of higher classes in colleges regarding the dangers to which they were exposed, and instruct them primarily on the various

prophylactic measures. The criticism was made that this desideratum was possible, but would not be the "professor of coitus" be a veritable innovation for the end of this century?

In France, M. Commenge recently stated, at a meeting of the Academy of Medicine of Paris, that he had collected the statistics of the number of diseased prostitutes found in the decade from 1878 to 1887: First, among women registered by houses or cards; second, among those women that — though registered — were the object of more or less frequent arrests, and constituted a special class under the name of *femmes du dépôt*; third and lastly, among the unsuspected, or women that lived by clandestine prostitution. The results obtained, based on nearly a million visits, showed the number of cases of syphilis in each thousand examined to be respectively 3.1, 2.7 and 23.9. Of other venereal diseases 3.0, 2.5 and 14.5.

The crusade against the Contagious diseases Act in England resulted in what would have been expected. From thirty to fifty per cent. of troops, quartered in garrison towns, were on the sick list with venereal diseases, while during the enforcement of the law the proportion so affected was very small.

It is only by the accumulation of such statistics that the fanatical sentiment against the regulation of prostitution can be overcome and the health of innocent women and children protected.

### PRESCRIPTIONS.

INFANTILE CONSTIPATION. — Bouchut<sup>1</sup> gives the following syrup in the constipation of infants:

R	Podophyllini . . . . .	gr. i.
	Alcohol . . . . .	5 iss.
	Syr. althææ . . . . .	3 iv. M.

A dessertspoonful is given daily.

FOR VOMITING, Lahnstein<sup>2</sup> recommends:

R	Menthol . . . . .	gr. i.
	Alcohol . . . . .	3 ll.
	Syrup . . . . .	3 iv. M.

Sig. A teaspoonful may be given every hour.

POWDER FOR MIGRAINE. — The following powder is recommended in *La Médecine Moderne*:

R	Citrate of caffeine . . . . .	gr. iss.
	Phenacetin . . . . .	gr. ij.
	Sugar of milk . . . . .	gr. iiii. M.

Sig. For one powder. This may be repeated, if necessary, in two hours.

SCABIES. — M. V. de Lollis<sup>3</sup> presents the following as very efficacious:

R	Creolin . . . . .	gr. viiss.
	Vaselin . . . . .	3 iss. M.

Sig. Anoint the affected parts thoroughly once daily.

The whole body could be rubbed with the ointment without causing any unpleasant effects.

FUCHSINE FOR CHRONIC ULCERS. — Rosenberg<sup>4</sup> recommends different solutions of which the following has been the most useful.

R	Fuchsine . . . . .	gr. xij.
	Alcohol . . . . .	aa 3 viij. M.
	Aque . . . . .	

The wound, after being washed with water, is well saturated with the solution, and a piece of lint soaked in the same solution is placed upon the raw surface, ordinary cotton wool is wrapped around the limb, and

bandages applied. This dressing is to be changed every two to four days. He has found a small glass syringe very useful in applying it, and cotton wool, which has not been deprived of its oil, will prevent it from penetrating the dressing.

## Correspondence.

### THE DISPENSARY ABUSE.

Boston, February 8, 1891.

MR. EDITOR:—No doubt the attention of some of your readers was called lately to an editorial in the *New York Medical Record*, on "Should a Poor Man Study Medicine?" and I dare say most of them agreed with the views therein advanced. The idea which the writer holds about the evils accruing to the poor man from the usual methods of treatment pursued in the dispensaries and hospitals of our large cities, strikes home very forcibly to those physicians and surgeons who practice in the heart of our own city.

It is generally agreed that the free treatment of our institutions shall be limited, so far as is possible, to those patients who are unable to pay for private medical service. That institutions of this kind are a blessing to any community, as well as a much needed charity, no one will deny; that they are no less a help to the profession than to the laity goes without saying, but they can become a serious disadvantage to the former when the objects for which they were founded are transgressed. In other words, when the dispensary and hospital treat patients who are perfectly well able to pay a physician, they transgress their proper functions, and rob from the man of private practice what justly belongs to him. A critic of one of the dispensaries in New York City, says: "On August 12th there were five hundred and sixty-eight patients treated, and judging from the appearance, we venture to say that three-fourths, at least, of them were abundantly able to pay for private medical service." This same criticism would be made, in all probability, were our critic to visit other cities where large dispensaries exist. However, to say that such a proportion of undeserving cases are treated in any of the Boston out-patient departments would be making a rather sweeping statement, but I don't think any one who has ever visited our hospitals will not say that every day scores of patients are treated who can well afford the ordinary medical fee. It does seem as if the out-patient physician and surgeon, in their desire to "build up the clinic" and to collect statistics, forget their brother in private practice, and (unwittingly I hope) perform a grave injustice. Many of those connected with the out-patient departments are men of means, who can wait for patients and who are content with aiding science instead of earning a livelihood, but the fact remains, nevertheless, that the dispensary in treating these unworthy cases does an uncharitable act to some members of the profession. It must be admitted a difficult task to draw a hard and fast line between the deserving and undeserving patient; yet if the duty we owe each other would only prompt some to make an effort in this direction, there would be no cause for criticism. How many times patients enter the doctor's office, after coming from the out-patient department, who are only too willing to pay the fee demanded, and how many times money has been offered the attending student in the lying-in clinics, there are not a few to testify.

So, then, does it not seem as if something could and should be done to limit the privileges of our out-patient departments to the needy and deserving poor? In a State like Massachusetts, where no law exists regulating the practice of medicine, and where one has to cope with all sorts of quackery, have we not a right to expect mercy and consideration from those who are able to bestow them?

Very truly yours, J. M. THOMPSON, M.D.

## RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, FEBRUARY 7, 1891.

Deaths reported 2,936: under five years of age 1,100; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 441, acute lung diseases 481, consumption 326, diphtheria and croup 134, measles 122, scarlet fever 52, typhoid fever 43, diarrhoeal diseases 32, whooping-cough 23, erysipelas 15, cerebro-spinal meningitis 12, malarial fever 8.

From typhoid fever Chicago 12, Philadelphia 11, Cincinnati 4, Brooklyn and Lowell 3 each, New York and Lawrence 2 each, Boston, Washington, Nashville, Charleston, Lynn and Quincy 1 each. From diarrhoeal diseases New York 11, Chicago 7, Philadelphia, Brooklyn, St. Louis, New Orleans 4 each, Cincinnati 3, Washington and Lowell 2 each, Cambridge 1. From whooping-cough New York 9, Brooklyn 6, Chicago 3, Boston 2, St. Louis, Cincinnati and Pittsfield 1 each. From erysipelas New York and Brooklyn 4 each, Chicago and Boston 2 each, Washington, Lynn and Waltham 1 each. From cerebro-spinal meningitis New York, Chicago, Cincinnati and Washington 2 each, Brooklyn, Boston, Worcester and Taunton — each. From malarial fever Brooklyn 4, New York 3, Philadelphia 1.

In the twenty-eight greater towns of England and Wales with an estimated population of 10,010,426, for the week ending January 24th, the death-rate was 25.1. Deaths reported 4,810: acute diseases of the respiratory organs (London) 636, whooping-cough 113, measles 93, scarlet fever 15, diphtheria 45, diarrhoea 133, whooping-cough 115, diarrhoea 50, scarlet fever 44, diphtheria 36, fever 26.

The death-rates ranged from 13.8 in Hull to 39.0 in Halifax, Birkenhead 29.6, Birmingham 27.3, Bradford 15.9, Liverpool 21.9, London 25.7, Manchester 29.5, Nottingham 21.5, Sheffield 25.6, Sunderland 22.9.

In Edinburgh 19.7, Glasgow 31.1, Dublin 38.4.

In the twenty-eight greater towns of England and Wales with an estimated population of 10,010,426, for the week ending January 31st, the death-rate was 22.3. Deaths reported 4,281: acute diseases of the respiratory organs (London) 636, whooping-cough 113, measles 93, scarlet fever 15, diphtheria 45, diarrhoea 43, fever 40.

The death-rates ranged from 13.2 in Nottingham to 32.9 in Preston, Birmingham 25.6, Bradford 19.3, Hull 16.1, Leeds 21.3, Liverpool 20.8, London 22.1, Manchester 27.9, Newcastle-on-Tyne 24.6, Sheffield 24.1, Sunderland 24.1.

In Edinburgh 24.4, Glasgow 35.4, Dublin 32.6.

## METEOROLOGICAL RECORD,

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 7, 1891, TO FEBRUARY 13, 1891.

Leave of absence for one month, to take effect on or about February 10th instant, is granted assistant surgeon R. W. JOHNSON, U. S. Army. Par. 1, S. O. 16, Dept. Arizona, Los Angeles, Cal., February 1, 1891.

Leave of absence for one month, to take effect on or about February 15, 1891, is granted Major WILLIAM D. WALTON, surgeon U. S. Army. Par. 2, S. O. 15, Dept. Platte, Omaha, Nebraska, February 7, 1891.

By direction of the Secretary of War, Captain JAMES C. MERRILL, assistant surgeon, is relieved from duty at Fort Reno, Oklahoma Territory, and will report in person at the earliest practicable date to the surgeon general U. S. Army, in this city for duty in his office. Par. 5, S. O. 29, A. G. O., Washington, D. C., February 5, 1891.

The leave of absence of seven days granted to Captain WILLIAM B. DAVIS, assistant surgeon U. S. Army, by Orders No. 2, Fort Phila., Maine, February 4, 1891, is hereby extended twenty-three days, with permission to apply to the adjutant general of the Army for a further extension of one month. Par. 2, S. O. 22, Hdqrs. Div. Atlantic, Governor's Island, N. Y., February 5, 1891.

# OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING FEBRUARY 14, 1891.

E. W. ANZAL, passed assistant surgeon, detached from U. S. S. "Boston" and to U. S. S. "Lancaster."

T. C. CHAPIN, passed assistant surgeon, detached from U. S. S. "Vesuvius" and to U. S. S. "Boston."

W. C. DRAKE, assistant surgeon, detached from Hospital, Hot Springs and to U. S. S. "Vesuvius."

H. B. FITZ, passed assistant surgeon, ordered to the Army and Navy Hospital, Hot Springs.

W. F. ARNOLD, assistant surgeon, ordered to the U. S. Reception-ship "Vermont."

S. J. BLACKWOOD, assistant surgeon, detached from the U. S. S. "Vermont" and to "Newark."

EDWARD ANDERIDGE, passed assistant surgeon, ordered to the Navy Yard, New York.

J. H. NORTH, assistant surgeon, detached from Navy Yard, New York and to the U. S. S. "Lancaster."

## SOCIETY NOTICES.

ROSES SOCIETY FOR MEDICAL IMPROVEMENT. A regular meeting of the Society will be held on Monday, February 23, 1891, at the Medical Library, Boylston Place, at 8 o'clock, P. M. Dr. H. Jackson, of Albion, N. Y., Etiology and Prognosis. Dr. G. W. Gray, of The Progress of some Venereal Cases after Union.

Dr. J. O. Green will show a Series of Preparations Illustrative of the Pathology of the Larynx.

G. G. SEARS, M.D., Secretary.

NEEDHAM DECEMBER MEDICAL SOCIETY. A meeting for business and Entertainment will be held at Armory Hall, 67 Warren St., Boston, Tue. Ev., February 24, 1891, 7:45 P. M.

Communication: "Tuberculosis and the New Treatment" (illustrated by stereoscopic views), by Harold C. Ernst, M.D. JAMES C. D. PIGEON, M.D., Secretary.

## CHANGES OF NUMBERS ON BOYLSTON STREET.

For the convenience of our subscribers who live on Boylston Street, Boston, and have recently had the numbers on their houses changed by the city, we give a partial list of the new numbers:

Blodgett, A. N., 390.	Marcy, H. O., 338.
Bowditch, H. I., 324.	Monks, G. H., 399.
Bowditch, Y. Y., 324.	Muro, J. C., 369.
Bush, J. F., 651.	Osgood, H., 396.
Cheever, D. W., 557.	Page, F. W., 543.
Cushing, H. W., 399.	Parker, A. H., 308.
Gay, G. W., 653.	Perry, J. F., 248.
Greenleaf, R. W., 561.	Shaw, H. L., 431.
Harrington, C., 807.	Storer, D. H., 476.
Jack, F. L., 437.	Thornick, P., 373.
Jelly, G. F., 361.	Wadsworth, O. F., 393.
Knight, F. I., 377.	Watson, F. S., 373.
Langmaid, S. W., 373.	Webber, S. G., 379.
Leland, G. A., 671.	Wesselhoeft, C., 659.
Lovett, R. W., 379.	Whittier, E. N., 647.

## DEATHS.

John S. Messersmith, M.D., Medical Director, U. S. N., with rank of Commodore, retired, died in Lancaster, Pa., February 16th, aged eighty-one years. He was commissioned, in 1837, by President Jackson, and was a member of Commodore Perry's first expedition to Japan. He served through the Mexican War and the Rebellion, being retired in 1872.

Dr. Karl Reyher, a distinguished surgeon of St. Petersburg, died from an accident on January 11th, aged forty-five.

Dr. Nicolas Gutierrez, founder of the Cuban Academy of Medicine, and also of the medical press of that island, died recently aged about ninety. In 1835 he was appointed Professor of Pathology in the University of Havana, and subsequently became rector.

## BOOKS AND PAMPHLETS RECEIVED.

Note on the Virile Reflex. By C. H. Hughes, M.D. St. Louis. Reprint. 1891.

Operation Blanks, Blocked. Prepared by W. W. Keen, M.D. Philadelphia: Lea Brothers & Co. 1891.

The Ninety-fourth Annual Report of the Boston Dispensary, with the By-Laws, Acts of Incorporation, etc. 1890.

The Breathing Movements in Relation to Voice Production. By G. Hudson Makuen, M.D., Philadelphia. Reprint. 1890.

Report of the Directors of the Boston Training School for Nurses Attached to the Massachusetts General Hospital for 1890.

Etudes sur la Rage, et la Méthode Pasteur. Par le Dr. Lataud, Rédacteur en Chef du Journal de Médecine de Paris, Seconde Edition. Paris. 1891.

Traité Élémentaire d'Anatomie Médicale du Système Nerveux. Par le Dr. Ch. Féré. Deuxième édition, revue, corrigée et considérablement augmentée, avec 242 figures.

Annual Report of the Supervising Surgeon-General of the Marine-Hospital Service of the United States for the Fiscal Year 1890. Washington: Government Printing Office. 1890.

Professor Koch's Method to Cure Tuberculosis, Popularly Treated. By Dr. Max Birnbaum. Translated from the German by Dr. Fr. Bröndicke. Milwaukee: H. E. Haferkamp. 1891.

Severe Vomiting during Pregnancy. A Collection and Analysis of Cases, with Remarks on Treatment. By Graily Hewitt, M.D., F.R.C.P., F.R.S. London: Longmans, Green & Co. 1890.

A Death Caused by a Uterine Dilator, with some Remarks as to the Proper Method of Using the Dilator. By Howard A. Kelly, M.D., Professor of Gynecology in the Johns Hopkins University. Reprint. 1891.

Hypertension Gravidarum as an Indication for the Induction of Premature Labor. By J. Henry Fruinight, A.M., M.D., Fellow of the New York Academy of Medicine, New York Obstetrical Society, etc. Reprint. 1890.

A Submembranous Local Treatment of Pharyngeal Diphtheria. By A. Seibert, M.D., Professor of Diseases of Children, New York Polytechnic, and Physician to the Children's Department of the German Dispensary. Reprint. 1890.

L'asepsie et l'antisepsie à l'Hôpital Bichat. Service de Chirurgie du Dr. F. Terrier (1883-1889). Par M. le Dr. Marcel Baudouin. Avec une préface et deux introductions de M. le Dr. Terrier. Avec 10 figures et 4 photographies.

## Addresses.

### EARLY DIAGNOSIS OF SOME SERIOUS DISEASES OF THE NERVOUS SYSTEM; ITS IMPORTANCE AND FEASIBILITY.

BY E. C. SEGUIN, M.D., PROVIDENCE, R. I.

#### V. EPILEPSY (SYMPTOMS OF, CONTINUED).

(6) THE post-spasmodic stupor is of considerable value in estimating the probability that a nervous "attack" is or is not epileptic. In the vast majority of cases of *grand-mal* a deep sleep of variable duration succeeds to the spasm and subsequent coma. In some instances the patient apparently regains consciousness, utters a few words or sentences, then lapses into sleep. On awaking there is no recollection of the remarks made. In other cases only a transient sense of dullness or sleepiness is experienced; and this is true of many cases of *petit-mal*. Very often in *petit-mal* there is not a trace of stupor after the momentary seizure; conversation being continued, or a muscular action kept up right away. There are cases of *grand-mal* in which no sleep occurs, but even in these rare cases a certain sluggishness in action and speech is evident for a time after a seizure. In hysteria, on the other hand, the patient usually is clear-minded and bright even after severe spasms, and always recalls what she may have said between recurring paroxysms.

In some cases of epilepsy and of hysteria, delirium follows the spasm, or *petit-mal*. In some epileptics transient seizures, overlooked by lay observers or careless physicians, are succeeded by delirious, co-ordinated actions seemingly intentional and deliberate; such as wandering off, stealing, committing murder (sometimes on a disliked person, thus apparently proving intent), yet, when the patient "comes to himself," hours, days or weeks after, there is complete amnesia of the things done and said. I am inclined to agree with Kraft-Ebing in holding amnesia a *sine qua non* for the diagnosis of epilepsy in such cases.

(7) Post-epileptic sensations. Often after *grand-mal*, patients feel sore, either generally, or more especially in one member (if this has been the seat of the chief spasm), as if they had been beaten, to use a common expression. Often also, there is headache of no definite distribution, and also a sense of exhaustion and languor. These symptoms help us to determine the occurrence of nocturnal seizures in the absence of witnesses. I have known the recurrence of soreness in the ball of one thumb, on a number of mornings, to lead to the diagnosis (verified by witnesses later) of nocturnal *grand mal*. A case came under my observation two years ago in which, on some five or six occasions, the patient (a bachelor) awoke with one humerus dislocated, suffering intensely from this, and also from general muscular soreness. On one occasion both humeri were dislocated. Strange to say, the diagnosis of nocturnal *grand mal* had not been made until all but the last dislocation occurred.

Other valuable evidences of nocturnal *grand-mal* are (1) the occurrence of minute specks or points of hemorrhage under the skin of the face and neck, discovered on rising. This sign has an almost pathognomonic value. (2) Emission of urine in bed, without awakening. This in adults who have not had the habit

of "wetting the bed," is strong presumptive evidence of an epileptic attack. In children it is, of course, a much less significant sign.

The occurrence of any of these symptoms (aching limbs and soreness, speck-like hemorrhages, enuresis), should make us insist on having some one sleep with the patient long enough to obtain an observation, before a positive diagnosis is made.

(8) Is any value to be attached, in the case of a patient who sleeps alone, to a dim recollection of an aura, or of something like an attack having occurred during sleep? Not infrequently our patients report some such dream-like reminiscence. I think that, usually, this is really a dream, that is, the patient dreams he has had an attack, and wakes with some faith in the dream. In my experience such reports have been made by patients who did not present the usual signs of a recent seizure. Unless the case be one of very strong and long signal-symptom or aura, I think that recollection of an attack is impossible; and it is generally recognized that amnesia is peculiarly complete in cases where it is known that nocturnal attacks do occur.

(9) There is still another means, not generally known, of distinguishing between hysterical and epileptic attacks, especially in those hybrid cases (hystero-epilepsy), in which symptoms of both orders are commingled; also of determining the truly epileptic nature of attacks which have occurred without witnesses, or are described by careless and incompetent ones. I mean the therapeutic test. As far back as 1873, I satisfied myself that an anti-epileptic treatment (bromide treatment) aggravated hysteria, particularly its spasmodic form, and subsequent experience has strengthened my opinion. To state it briefly: a tonic treatment, especially by strychnia in full doses, benefits hysterical cases, while it causes (except in a small number of cases of *petit-mal*) increasing numbers of spasms, and more severe spasms in epilepsy. Contrarily, a bromide treatment reduces the number of, or completely prevents, attacks of a truly epileptic nature, and the same treatment aggravates hysteria. I would not be too dogmatic about the value of this rule, but it is certainly one of much practical value. Especially have I been satisfied with its application in the (not rare) cases of epileptoid spasms of young children between eight and fourteen, which are, especially in boys, much more often than is supposed, hysterical. In such cases we also have, as guides to a correct diagnosis, very prolonged spasms, co-ordinated or dramatic spasms, absence of enuresis and of post-epileptic stupor, and the fact that the eyes are *firmly* shut in the seizures.

It will be said that I have given too much time to the analytical study of the symptoms of epileptic attacks. The disease is so common, and its diagnosis so often difficult, that I think I am justified in detailing the foundations for a correct inductive diagnosis.

Let me add a few remarks of a more general nature.

The errors usually made in the study of epileptic cases are two, namely: (1) Underestimating or not appreciating the meaning of a first attack of *grand-mal*; (2) not recognizing the epileptic nature of slight, simple *petit-mal*.

(1) I have elsewhere treated at some length of the difficulties attending the diagnosis or estimation of a

<sup>1</sup> Delivered before the Providence Medical Association, December 1, 1890. Concluded from page 181 of the Journal.

first convulsion in childhood.<sup>18</sup> I have there related several cases in which attacks of *grand-mal* were treated by able physicians as eclamptic or symptomatic; usually of gastric origin. In many cases no proper treatment is directed until quite a number of spasms have occurred, spread out over long but diminishing intervals, and the "epileptic habit" has become established. I will not repeat the arguments<sup>19</sup> I there advanced to show that after the third year of life, symptomatic (eclamptic) spasmodic attacks are rare. They do occur occasionally, in very excitable, neurotic subjects after that age, but I repeat, very rarely, until we reach the age when uræmia and syphilis appear as potent factors of epileptoid seizures. In the first two years of life there is great convulsibility, if I may be allowed the word, and such causes as intestinal, preputial (vulvar) dental irritations may give rise to spasms which are precisely like those of epilepsy. During the same period, and a little later in irritable subjects, the onset of acute disease (exanthemata, pneumonia, malarial fever, etc.) may be characterized by an epileptiform seizure. Consequently, if the attacks are very few in number, and *always* accompanied by a decided exciting cause, we may call the attacks eclamptic, and hope that there will be no succeeding ones. But after the third year, and during the first few weeks of life, an epileptiform attack, *is*, in my experience, the beginning of the long and fatal chain of attacks which we call epilepsy. After a second seizure, in my opinion, especially if the attacks were not accompanied by very strong evidences of peripheral irritation sufficient to cause a spasm, a cautious bromide treatment should be begun and kept up for several years.

In adolescents and adults the diagnosis of a first or second attack is less difficult. We need here to exclude hysteria, extreme excitability of the nervous system (allowing of a late eclamptic or reflex seizure), uræmia, and syphilis inherited or acquired. Yet in the syphilitic cases the attacks may rightfully be designated epileptic, as contradistinguished from spasms caused by reflex action. Even at the menstrual period, an epileptiform attack occurring in a girl is probably the beginning of epilepsy. In adults, uræmia is the factor to be most carefully eliminated, especially if the first seizure has been a *status epilepticus* with long-continued stupor. In uræmia the spasm is less distinctly tonic at first, biting of the tongue is rare, small pupils are the rule. The temperature may be high as in epilepsy, and it should not be forgotten that uræmic spasm, like Jacksonian epilepsy, may be hemiplegic or one-sided. Examination of the urine is not as valuable a test as might be expected *a priori*, for albumen may appear in the urine as the result of a truly epileptic attack, and on the other hand, uræmia so-called, may be present without albuminuria and only few casts. The examinations of the urine should be frequently repeated (three or four specimens in each day) during the two or three weeks succeeding the seizure. In this way evidence of chronic interstitial nephritis may be obtained. There are, I believe, rare cases in which eclamptic attacks precede the appearance of objective signs of renal disease in the urine, several such attacks recurring at long intervals before the diagnosis of cirrhosis of the kidney

can be made. As regards syphilis, it is of the utmost importance to recognize it, but its discovery does not relieve us of the obligation of beginning a mild anti-epileptic treatment, as well as an anti-syphilitic treatment, after the first seizure.

In case of doubt in an adolescent or adult, as to the real significance of a first or second epileptiform attack (that is, as to whether it is truly epileptic or symptomatic), I think the best course is to begin a moderate, carefully watched bromide treatment, and continue it a long time. If properly managed in a subject not unusually affected by the bromides, I firmly believe that such a course will do no harm, and may, probably will, cure the beginning epilepsy.<sup>20</sup> If we hesitate, and postpone an anti-epileptic treatment, how great a responsibility is thrown upon us. Each recurring attack diminishes the prospects of a cure in an enormous ratio I believe, and after three, six, eight convulsions, spread out it may be over a period of two or three years, the case is probably incurable. I would repeat what I said at the beginning of this section, that if there is any disease the curability of which depends on its recognition at the earliest possible moment, that disease is epilepsy. Lastly, if it appears that we have given a long-continued bromide treatment to a non-epileptic person, after an eclamptic attack, no special harm has been done. It is a serious dilemma for the physician, but to my mind there is no doubt as to which course should be chosen for the patient's welfare.

(2) The non-recognition of *petit-mal*. This is a very frequent error on the part of parents and of physicians as well. The "spells" are so slight that they surely amount to nothing; they come from the stomach; they will pass off when the child is older, etc. Numberless reasons are given for the neglect of these cases. Another fatal misconception is that such "dizzy spells" will cease when menstruation is established; a most absurd notion. If you will pardon a digression, I will speak here of the dangerous error, popularly universal and indulged in by too many physicians, that chorea and epilepsy are benefited by menstruation and by marriage. In my experience nothing could be more erroneous and dangerous, especially as regards marriage. Neuroses are aggravated by both these events, and we should use all our influence, I believe, to prevent the marriage of epileptics. I have known marriage to be *prescribed* for epilepsy to both male and female subjects, in all cases with very bad results, physically and socially. Such practice is deserving of the strongest condemnation.

The question of the marriage of epileptics, apart from this fanciful therapeutic influence, is one often presented, and each case requires separate judgment. In general I am opposed to the marriage of any epileptic, yet exceptions occur. For instance, if the patient be a woman, and the prospective husband fully understands the circumstances, if she is not herself very degenerate or come of degenerate stock, if her attacks are under control, and if the man be not neurotic or degenerate, I would consent to the marriage. I have studied the children issued of two or three such marriages, and see

<sup>18</sup> *Opuscula Medica*, p. 31, et seq. (New York Medical Record, August 6 and 13, 1871.)

<sup>19</sup> *Ibid.*, p. 31, et seq.

<sup>20</sup> The fear of dementia from bromism is prevalent in the minds of physicians and laymen. It is based on the results of reckless, unsystematic giving of bromides, producing toxic effects. I have repeatedly received patients in this condition, and still having attacks, and have been able, by *care*, to reduce the doses of bromide, restore their intelligence, and diminish the number of attacks still further. It should be remembered, and impressed on parents that it is the epilepsy which causes dementia, as was perfectly recognized by authors writing before bromides were used.

no reason to regret my action. In the case of a male epileptic the question is more serious. He is supposed to be the bread-winner and protector of the wife and family, consequently very slight remains of the dread disease should positively prohibit marriage. Given the case of a healthy young epileptic, not degenerate, not of degenerate stock, who has had no attack for four years, under treatment, I might give consent, but only on condition that the *fiancée* should know all particulars, and fully appreciate the possibility of a return of the disease, and of disability of her husband. It is, gentlemen, a question which comes very close to our conscience, and we should not allow any sentimental notion to bias our judgment. A newly-married man or woman may honestly swear to care for an infirm (epileptic) wife or husband, yet after a few years of contact with the repulsive symptoms of the disease, especially the moral perversion which characterizes it (so few epileptics can be good, true or kind), it becomes humanly impossible to fulfil the promises, and cruel wrong results, besides the possible tainting of the offspring.

To return to *petit-mal*, the points for its diagnosis have been given above. I beg you not to underestimate these slight symptoms, but to institute a thorough treatment as soon as possible. A remarkable fact, noted by many observers, is that *petit-mal* does not yield to bromide treatment as readily as *grand-mal*. Indeed, many cases show no improvement even when bromism is well marked, and I must admit that we, as yet, know of no indications for the use of other remedies. It is a hap-hazard, experimental treatment. Some cases yield, as if by magic, to strychnia, others to atropia, some to ergotin and digitalis. I have exhausted my materia medica in some few cases without materially reducing the number of attacks (often many each day). It is always a painful surprise for parents when you tell them, as you should, that these slight "spells," hardly worth mentioning, are much more difficult to control than convulsions, and that they are just as likely, if not more so, to affect the child's intellect.

For many of the minor points in the diagnosis of *petit* and *grand-mal* in children I would again refer you to my former paper.<sup>21</sup> As an encouragement I might cite here a case which has been under my care for the past two years; slight dream-like *petit-mal* in an adult, no convulsions. With a moderate dose of bromide of sodium (three grammes) on rising, and cannabis indica 0.02 three times a day, tonics and hygiene, an interval of nearly a year has been obtained. The patient had had for several years attacks almost every day. Dementia was slightly but distinctly marked when I first saw him, but his mental action has become better and easier in the last year, in spite of great business responsibilities.

Pardon me, if, before such an audience, I have touched upon so many trivial points. My experience as a specialist has shown me that the diseases treated of in this paper are not recognized as early as they should be and can be, if the general practitioner will give *attention and time* to the study of his cases by the analytical method. Especially in epilepsy is an early diagnosis urgently demanded, because it is the most curable of the diseases mentioned. Pray believe me when I tell you that you will never regret having made an early diagnosis of tabes, dementia paralytica, spinal disease, cerebral tumor and epilepsy; whereas we all

look back with self-reproachful feelings to having failed to recognize these affections early, and to institute proper treatment, medicinal or hygienic.

## THE RELATION OF ORTHOPÆDIC SURGERY TO GENERAL SURGERY.<sup>1</sup>

BY NEWTON M. SHAFFER, M.D.,

Attending Surgeon in charge of the New York Orthopædic Dispensary and Hospital.

GENTLEMEN:—It has been for several years the special function of the New York Orthopædic Dispensary and Hospital to aid in the development of purely orthopædic methods. Its work has been to develop and improve the much neglected branch of mechanico-therapy. It has devoted much time and effort to the early recognition of the deforming diseases, especially of childhood, and it has aided in devising methods not only for the prevention of deformity, but also for relieving or curing it after it has occurred. While the general surgeon has been occupied in bringing operative surgery to its present very high standard of efficiency, your Institution has been working in a field of almost equal importance—though far less brilliant and far less attractive to the rank and file of the medical profession.

The operative side of general surgery has always been well taught in all the medical colleges and universities. On the other hand, there has been in the same institutions an almost general neglect of orthopædic surgery—a department of surgery almost as important as operative surgery itself, and one which is of great value to the human race. Your Institution has been content to work in those lines which would aid in removing the unjust opprobrium that attaches to mechanico-therapy, and in demonstrating the usefulness and the wide range of properly applied mechanical principles of treatment.

In short, your Institution has been steadily working upon conservative lines—neither ignoring the great strides in general surgery, nor forgetting its own mission. Its efforts have been rewarded in more ways than one. The steady increase in the number of patients which have sought your services was mentioned in the last Annual Report; and while orthopædic institutions and orthopædic departments of institutions and orthopædic clinics at the colleges have multiplied in New York City and elsewhere since this Institution was organized in 1866, it still remains a fact that a large percentage of the patients which apply to your Institution for treatment have previously had no orthopædic treatment at all; and while there are now quite a number of places to which the poor cripple may apply, so broad and so generous is the philanthropy of New York, the important orthopædic institutions of our city are overcrowded, and some of them, like our own, are asking for more room and increased facilities.

The subject of mechanico-therapy is so important and its future usefulness is now so well assured that we, as an Institution, may well feel proud that our efforts have been so steadfastly directed toward its development. The general surgeon, whose ample and easily obtained training fits him to perform the cutting operations for the relief of deformity, finds himself

<sup>1</sup> An address delivered before the Trustees of the New York Orthopædic Dispensary and Hospital—upon the occasion of its Twenty-third Annual Meeting.

<sup>21</sup> Opera Minora, p. 519, et seq.

fully occupied in keeping abreast with the current surgical thought and literature of the day. The dextrous operator finds his time fully taken up in his peculiar and special work. But there is another side to surgery. The joint, for example, that is excised in many instances may be saved; the limb condemned to amputation on account of its deformity may in many cases, be straightened. Properly applied mechanico-therapy will save many of the deformities that fall into the hands of the operative surgeon. Indeed, many of the deformities that were formerly almost habitually operated upon can be relieved or cured by orthopaedic measures without operation. But, if a patient with deformity reaches a point where orthopaedic measures are contraindicated, or useless—or where a surgical operation, with ordinary surgical dressings only, are necessary to remove the deformity, he should at once be placed under the care of the general surgeon. Orthopaedic surgeons, in short, ought to limit their work to their own department—in which there is enough to do and enough to learn, without interfering in the slightest degree with the already overcrowded ranks of the general surgeon.

Orthopaedic surgeons have until recently been placed at a great disadvantage. The early followers of true orthopaedic surgery—and some of them are alive to-day—were necessarily self-educated in orthopaedic methods and work. They had no school or college; no hospital or dispensary to which they could go to receive instruction in orthopaedic surgery. Equipped as regularly educated men, amply prepared to amputate a limb or excise a joint, etc., they were not taught even the simplest rudiments of mechanico-therapy. They might have been told that "Smith's club-foot shoe is the best," or that "Jones's knock-knee instrument is superior to Brown's"; but of the mechanical principles involved they were taught little or nothing. In addition to this, they had to meet and overcome the still existing opprobrium that attaches to the subject of mechanical treatment. They had also to meet the criticism that "Dr. X. could perhaps apply a club-foot shoe pretty well, but he could not amputate a limb as well as Dr. Y."—as if any means that relieves human suffering is beneath the dignity of the most highly educated and accomplished surgeon that ever lived.

This is becoming changed. There are several places where the seeker after orthopaedic knowledge may find opportunities for study; and while it is difficult to remove the old prejudice that exists, especially outside of New York City, it will not be long before orthopaedic surgery, *per se*, will occupy its legitimate place in the estimation of the entire medical profession. In the meantime, orthopaedic surgery needs men who will work and wait,—men who will patiently investigate the many unsolved questions that confront it on all sides; men who will devote themselves to a true specialism, and who will steadfastly refuse to compete with the general surgeon in the field of operative surgery.

We have only to look about us to see how fully the field of general surgery is occupied. No one in the civilized world, requiring the services of the general surgeon, need go unrelieved. The general hospitals of all countries are numerous and well-equipped, and this is especially true of our own great city. On the other hand, what are the special provisions made for the treatment of the deformed? There are comparatively few surgeons in the whole world whose early

education and training fit them to intelligently apply apparatus to the conditions of deformity. In some of the large cities, both here and abroad, there are orthopaedic dispensaries and hospitals, but the surgeons connected with them and controlling them are too frequently men with strong operative instincts and training—surgeons who are accomplished in all that pertains to diagnosis, the conventional surgical dressings and the use of the knife, but who are necessarily lacking in the special training required to successfully apply the fundamental principles of mechanico-therapy to an average case of progressive deformity. They are, by nature and education, operative surgeons who duly recognize the value of mechanico-therapy, but they are, I think, too often willing to relegate the mechanical detail of treatment, both before and after operation, to the uneducated instrument maker, whose interest in the patient is merely a commercial one. It is largely so in England, France and Germany,—it is only less so in America. At the same time, there are quite a number who are, strictly speaking, orthopaedic surgeons, whose education is based upon an early and prolonged training in orthopaedic methods, and it is to these men that we must look, I think, for the advancement of true orthopaedic surgery.

It must be apparent that it is only by special effort and prolonged study and work that any department of medicine can reach its maximum of benefit to the human race. The history of Medicine proves that many of its greatest advances have been made by broadly educated men who have devoted themselves to special branches of work. And so it is in Orthopaedy. It is not the surgeon who amputates a thigh, reduces a fracture or a dislocation, and applies a hip splint the same day, that is likely to advance orthopaedic science. It is more likely to be the surgeon who, with the wide and almost unexplored field of mechanico-therapy before him, devotes his life to demonstrating its great value in the various conditions of deformity and deforming diseases.

The function of the orthopaedic surgeon should therefore be to fill a place not occupied by the general surgeon—to do a work that the general surgeon is either unwilling or unfitted to undertake, and to aid in developing an important department of surgery which has been too long neglected or ignored. Those deformities which general surgery is competent to relieve, without the intervention or aid of the orthopaedist, should be placed at once under the care of the general surgeon; while, on the other hand, chronic cases requiring special mechanical treatment, either in the prevention or cure of deformity, should be placed under the care of the orthopaedic surgeon.

It is my experience that a longer training is necessary to fit one to be an orthopaedic surgeon than to fit one to be an operative surgeon. The brilliancy of operative work attracts many of the best men in the profession, while the hard and rugged work of mechanico-therapy seems to repel many who are adapted to orthopaedics; and yet the work of the orthopaedist may be called an exact science. He is dealing with mathematical and mechanical problems all the time. He has a definite object in view, and his therapy is controlled by his own hands. He is limited in the application of his principles of treatment only by the vulnerability of the human tissues; and while he may be in doubt as to the best "method" to be employed he is never in doubt as to the ultimate principles of treatment.

The field of orthopaedic surgery is therefore a very wide one—so wide and so comprehensive that one engaged in its practice need not encroach on the field of the general surgeon. Still, the orthopaedic surgeon should be an educated operative surgeon—and he should be prepared to operate upon any patient who *requires special mechanical treatment after operation*. But the operative treatment should be secondary to the mechanical, and the element of conservatism should necessarily enter largely into the work. The patient mechanical work—may be of years—necessary to save a limb or joint from deformity, may be less brilliant than the operative means that removes them, but the real merit lies in that method which saves the limb and restores the affected individual to society with a useful member.

In an essay read before the International Medical Congress held in Berlin in August last the writer raised the question, "What is Orthopaedic Surgery?"<sup>2</sup> and he ventured to define it as follows: "Orthopaedic surgery is that department of surgery which includes the prevention, the mechanical treatment and the operative treatment of chronic or progressive deformities, for the proper treatment of which special forms of apparatus or special mechanical dressings are necessary."

The conclusion formulated in this definition is based upon nearly twenty-two years of work in your Institution—seventeen years spent in the orthopaedic ward of St. Luke's Hospital, combined with an early training of five years in the New York Hospital for the Relief of the Ruptured and Crippled. It places your Institution on record as being the first to formulate a definite plan of work, which separates orthopaedic from general surgery, and which aims to cover a definite field not included in that of the general hospitals and dispensaries.

#### ON THE EXTRACTION OF THE AFTER-COMING HEAD AND ARMS.<sup>1</sup>

BY EDWARD REYNOLDS, M.D.

THE extraction of the after-coming head and arms is a procedure familiar to all, but so many methods are in use, and the preferences of individual operators for one or the other vary so widely, that a *résumé* of the writer's experience with the different plans in vogue, considered in reference to the different conditions which present, may be of some interest, if only by provoking an expression of the views of the other members of the Society. The methods which I propose to discuss are the release of the arms by bending the body downward or upward; the extraction of the head by the method of Prague; by combined traction, with or without supra-pubic pressure; by Martin's method; or by the use of forceps; and the release of the head and arms together by the method known as Deventer's.

The choice of operation for the release of the arms seems to me to depend wholly upon the portion of the pelvis at which the arrest of the shoulders occurs. When the disparity between the child and the bony

pelvis is so great that progress is arrested at or about the time when the point of the scapulae appear, but one method is applicable. The back must be turned towards one side of the pelvis, the body drawn sharply upward to that side, and the half or whole hand passed boldly upward in search of one arm, of which the posterior is usually the more easily reached. In such cases, if the adaptation is only moderately tight, the arm may sometimes be brought most easily within reach by making strong traction upon the body before the hand is passed into the vagina, and attempting to bring the posterior arm to the lowest possible point in the pelvis by forced flexion of the trunk around the lower edge of the symphysis, but in the more difficult cases it has seemed to me better to make no attempt to strain the arm downwards, but, on the contrary, to try to gain greater space for the introduction of the hand by pushing the trunk gently upwards, in order to lessen the engagement of the shoulder and so afford space at the brim; and I think that in this procedure, if the back of the hand be well greased before introduction, the fundus of the uterus carefully washed and the body of the child held immovably by gentle traction downwards with the disengaged hand, the internal fingers may be made to reach the extended elbow without the employment of injudicious force, without subjecting the uterus to any essential risk, and in most cases without lacerating the perineum.

When version is done for the relief of some condition which necessitates prompt delivery, and in a pelvis which affords ample space for the passage of the child, or when in contracted pelvis, the transverse space is ample, it is usually possible to bring the points of the shoulders into view before arrest occurs. In such cases, my preference is distinctly in favor of the plan of dropping the body towards the floor with the back looking directly upward, swinging it to one side in order to depress the corresponding shoulder, and then attempting to release the arms by passing two fingers over the shoulder and along the upper arm into the concavity of the elbow.

After the release of the arms, the method which should be preferred for the release of the head depends, in my opinion, upon the form of pelvis present. With a normal pelvis or with a flattened pelvis in which the transverse space is ample, I prefer to resort at once to the method of combined traction upon the face and shoulders, aided by supra-pubic pressure by an assistant. In this procedure the fingers of the internal hand should be placed at once, if this be possible, upon the canine fossae of the child, in preference to its mouth, the other hand should be hooked about the shoulders, and traction made as nearly as possible in a direction vertically downward until the resistance of the superior strait has been overcome; but a point of considerable importance is that the fingers and wrist of the internal hand should be made to arch away from the face and body of the child in such a way as to admit air to its mouth, a precaution which may save the lives of many children which would otherwise be lost by asphyxia during the extraction. In my own experience I have several times seen the chest fill with air while the head was still in the superior strait, and have thus saved several children which would probably have been lost without this precaution. The assistant should be directed to apply his pressure in the axis of the superior strait, to apply a gentle force at first, and increase it rapidly but gradually, until the maximum effort is

<sup>1</sup> New York Medical Record, September 27, 1896.

<sup>2</sup> Read before the Obstetrical Society of Boston, December 12, 1896.

attained. It is a matter of some importance that he should apply his hands over the head itself, rather than to the fundus, which, with its contained placenta, may usually be felt as a soft mass above, and frequently somewhat behind the head, since a neglect of this precaution may possibly result in rupture of the uterus by excessive increase of the internal fluid pressure.

When the pelvis in question is simply flat, and possessed of ample transverse space, I have sometimes found it easier to bring the head into the superior strait by the method of Prague, which consists in traction upon the body directly downwards and towards the floor before resorting to combined traction; but whichever method is used, I am sure that success in extracting rapidly, easily, and with a minimum degree of force in these cases, is almost wholly dependent upon an accurate observance of the mechanism of natural delivery of the after-coming head through such a pelvis.

When the pelvis is flattened and the transverse space ample, the after-coming head enters transverse, and is placed bodily to that side of the pelvis towards which the occiput is directed, so that the parietal protuberances occupy the largest antero-posterior diameter (that which is opposite to the sacro-iliac notch), while the smaller bi-mastoid and bi-temporal are engaged between the promontory and symphysis. The bi-temporal thus remains arrested, while the bi-parietal advances through the brim, the movement resulting in a marked extension of the head. So soon as the occipital end of the head is released from the superior strait, the pressure of the uterus is concentrated upon the forehead, the bi-temporal is driven past the conjugate and flexion is established. From this it follows that during artificial extraction by the combined method, the efforts of the internal hand should, in such cases, be confined to watching the movement of extension until the release of the occiput is perceived, a phenomenon which occurs at about the time when the horizontal ramus of the lower jaw is at right angles with the neck, the traction which is applied to the shoulders by the external hand should then be reduced to a degree of force which will just maintain what has already been gained, while the internal hand is made to sharply flex the head, a change which may usually be effected with the greatest ease if the attempt is not made too soon; rotation and the remainder of the extraction then usually follow with the greatest rapidity.

The use of forceps to the after-coming head has been warmly advocated by many operators, and as strongly disapproved by others. I cannot but think that their use or disuse is a matter which must be left, for the most part, to the personal equation of the individual physician, but my own experience has been, that in simple flat and normal pelvis, forceps are less powerful than manual extraction; but that, when it is necessary to deliver the after-coming head through a pelvis in which the transverse space is insufficient, and in which the head enters in a well-marked oblique position, the forceps are, upon the other hand, more efficient than manual methods; but although I have several times, in such cases, succeeded in delivering the after head by forceps, after failing with my hands, I have never succeeded in saving the child, and I cannot help believing that if an operator of ordinary skill and muscular power devotes himself persistently to manual extraction, and employs from the start, the maximum amount of force which he considers justifiable in the

given case, he will succeed in almost every instance, and I think, perhaps, in all instances, in extracting by such means any child which he could extract alive by an original application of forceps; that is, I believe that when a given head is beyond the power of manual extraction, its delivery by forceps may necessarily involve an amount of compression which is in itself about as dangerous to foetal life as is the use of the perforator, and far more dangerous to the mother.

My experience with Martin's method, which consists in flexion of the head by pressure upon the face per vaginam, in combination with supra-pubic pressure upon the occiput by the other hand of the operator, has been very limited, but so far as it has gone, has been decidedly favorable to the expedient.

The method known as Deventer's, in which the after-coming head and arms are extracted together, is one which is little known and practised, but one which I believe to be well worthy of much greater favor than has hitherto been accorded it. It was introduced and advocated by a French accoucheur of that name, early in the eighteenth century, fell into disuse, but has been revived during the past few years by several American obstetricians. When this plan is adopted, the body is extracted in the ordinary way until the points of the shoulders appear; the shoulders and feet are then seized by the hands, exactly as in the Prague method, and traction is made vertically downward towards the floor, no attention being paid to the arms. The mechanism is as follows: the chin catches upon the coccyx and lower portion of the sacrum, the arms are in apposition with the elastic and yielding sacro-seatic ligaments, and by stretching them outwards, add so much to the pelvic space that they fail to interfere with the movements of the head; the head extends, the occiput appears at the arch, the perineum is retracted by the neck and chin, the occiput is born by extension, the face follows, and the arms remain in the vagina until after the delivery of the head.

During the last three years I have employed this method a considerable number of times with the following results: it is totally unsuccessful where the head and arms are arrested at the superior strait; and it is less valuable than other plans when the antero-posterior diameter of the brim is so much contracted as to arrest the head, and the transverse diameter sufficiently large to permit passage of the shoulders; but when version is done in the interests of immediate delivery in normal pelvis, or for arrest due to other causes than extreme disproportion, that is, when the points of the shoulders appear at the vulva and the head is not firmly arrested by the superior strait, the manœuvre is superior to all others in the very important particulars of ease and rapidity. It is so simple that the most inexpert operator can hardly fail in its performance, and occupies but a fraction of a minute after the shoulders are in sight.

I am now inclined to employ it in all such cases. It was originally urged by Deventer, and has been claimed by his followers that if the perineum was not injured by the extraction of the breech and body, it is never torn during the delivery of the arms and head, a point which is fully corroborated in my own cases, and which is in striking support of Emmet's belief that laceration of the perineum is caused by its extension outwards and forwards, and not at all by any backward tension which may be exerted upon it.

## A SURGICO-LEGAL CASE.

BY C. W. STICKNEY, M.D., HOLDEN, MASS.

A SUIT for alleged malpractice has recently been decided in the Superior Court at Worcester, and seems to possess sufficient interest to the profession at large to make it worth putting on record. In fact, most of the cases leading to law-suits are of interest to the profession generally—or at least should be—inasmuch as these suits are at the present time quite fashionable. Three cases of the kind were entered for trial at the long term of court at Worcester this winter: two of them have at this writing been disposed of—the third still remains for trial. True, it is not very common for a jury to award damages, but the expense of defending these suits is a considerable item, and any plan to discourage parties from bringing them should meet with favor among reputable physicians.

In this case the plaintiff is Mrs. William M. Prescott of Northampton, formerly of Holden. On the 12th of July, 1888, being then fifty-seven years old, she fell from a load of hay, injuring both wrists. The left wrist I found severely sprained and contused—that combination of circumstances well expressed by the term “concussion.” The right wrist was partially dislocated, that is, the carpus was thrown partially backwards from its articulation with the radius, producing something of a silver fork deformity, but occupying a position lower down than is usually found in fracture of the lower end of the radius. The dislocation was readily reduced by extension and manipulation, the patient declining anæsthesia. Both wrists were bound up with splints.

The next day I visited her and reapplied the splints, reassuring myself by careful examination that there was no other displacement of bones and no fracture anywhere. At this visit she refused further attention at the house, saying she would come to my office, or would send for me if needed. I remonstrated with her, telling her it was not a safe way to deal with so serious an injury, but to no purpose. She insisted on paying me for those two visits, and being considered as an office-patient thereafter. Finding I could do no better, and feeling that it was my duty to do the best I could under the circumstances rather than abandon the case, I directed her to present herself at the office in two days—three at most. Toward the end of a week she came to my office; wrists doing as well as could be expected. In a few days more she came again; probably ten to fourteen days after the injury. Still nothing to cause uneasiness; only the swelling and tenderness natural to such injuries. On this occasion she asked if I thought it safe for her to go to Lawrence and stay with her daughter a few weeks. I said she might as well be in one place as another; “but,” I said, “wherever you go you must put yourself at once under the care of a competent surgeon, who should see you at least twice a week.” I explained the necessity for skilful supervision with passive motions and the like, telling her that if she neglected it the results were almost certain to be unsatisfactory.

She left town soon after, and I did not see her again until the 28th of August. Then she presented herself at my office with wrists distorted by contractions of tendons, and bound in their abnormal positions by adhesions; fingers almost immovable, and the hands practically useless. I asked if she did as I told her,

and she said that after she had been in Lawrence three weeks or so, she had consulted “the best doctor in Lawrence” (she referred to Dr. C. N. Chamberlain), who told her that “as far as he could see the wrists were all right, but needed straightening,” that is, there was no displacement of bones, but the adhesions and contractions should be dealt with. He offered to etherize her and operate, but she declined his proposition, saying that she would not take ether anyway, and would go back to Holden for treatment. That his judgment was correct could not be doubted; but, as she would not consent to take ether, I could not proceed radically to break up the adhesions and restore the mobility of the joints, but was forced to content myself with the slower method by passive movement with massage, etc.; and right here I may add that, as the sequel shows, I believe this method would have resulted as favorably as the more radical plan. She came to me only once more, however; at that visit the wrists and smaller joints of the hands showed decided increase of flexibility, and left no reason to doubt the ultimate restoration of the usefulness of the hands.

Not content with this, however, she went soon to a “bone-setter,” one Sweet of Worcester, who, with the assistance of a homœopathic practitioner of the same city (Dr. J. K. Warren), broke up the adhesions under ether (to which she at last consented), and after about six months of treatment left her with fairly useful wrists.

At the trial plaintiff claimed to have paid me at each of the two visits at her house, claiming it was her custom to pay her bills in that way. She admitted, however, that she had not paid the “bone-setter” in that way, and my records of the case sustained my statement that she paid me for both at the second visit. A witness also corroborated me by saying that she heard plaintiff direct me not to go to her house again. Another witness heard her say, a few days after the accident, that her wrists “were doing nicely”; whereas she claimed to have suffered severely and continually with them from the first. My evidence relative to directing her to put herself under treatment at once on reaching Lawrence she flatly contradicted, and neither could be corroborated.

But the chief interest of the case centred in the remarkable testimony of the “bone-setter.” When asked about the condition of the wrists when she went to him, he said there was a *dislocation in both wrists!* Only a few days after I had seen the patient, only a few weeks after the “best doctor in Lawrence” had pronounced the wrists all right—save for the adhesions—this “man of intuition” discovers that both wrists are dislocated! And further discovers a fracture of the radius one-half inch from its lower end! And Dr. J. K. Warren—whose memory by the way was very poor, and who unfortunately made no notes of the case—*thought* both wrists were dislocated, and said on the stand that “he had an impression that it was his impression at the time that there was a fracture of the radius” (only he located the fracture in the opposite wrist as regards his colleague’s evidence)! The “bone setter” was unable to explain what he meant by a dislocation, but thought “some of the small bones of the wrist were out of place.” He further thought “that if only one or two of the small bones were displaced it would be a partial dislocation,” and that a complete dislocation meant “the displacement of

all the bones." He appeared totally ignorant of the fact that dislocation of one or two bones of the carpus from the others of the carpus is one of the rarest of accidents, and well nigh impossible as the result of a fall upon the hands. In fact, he admitted that he is entirely innocent of scientific surgical knowledge and of anything more than the most superficial knowledge of anatomy, and yet laid himself out before the jury with an arrogance and an assumption of superiority over common, educated surgeons—such as has not often fallen to my lot to witness. Of course, it was not difficult to show by competent surgeons that the fracture of the radius sworn to would undoubtedly leave a callus at its original site—particularly if it had remained unredressed for two months; but neither Dr. S. B. Woodward nor Dr. J. B. Rich, who were summoned as experts, could find any evidence of previous fracture. These gentlemen also gave valuable evidence touching the surgical points raised, and in such a manner as to make themselves fully understood by the jury.

The plaintiff thus attempted to show, on the part of the defendant, a want of conception of the gravity of the injury, with consequent failure to adjust the parts properly, and hence improper treatment; the defendant maintained and held that the original diagnosis and treatment were correct and that the evil result, other than what could properly be attributed to the injury itself, was the result of the plaintiff's own neglect in refusing to allow defendant to treat the case as he saw fit, and in her failure to place herself under treatment in Lawrence after leaving him. The jury returned a verdict for the defendant.

## REPORT ON THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M.D.

### ALCOHOL AND ALCOHOLIC SOLUTIONS IN THE ABORTIVE TREATMENT OF HERPES.<sup>1</sup>

Dr. DUPAS, of Lille, gives the following directions for this common and often troublesome condition.

Alcohol of ninety per cent. strength, or a solution of two parts of resorcin to one hundred of alcohol, can be employed as a dressing; or, one per cent. of thymol or three per cent. of menthol in ninety-five per cent. alcohol. If the solutions cause too much pain, a little cocaine may be added. Compresses moistened in one of these solutions are to be applied to the lesions, and over this spread some impermeable material, or absorbent cotton may be used. These dressings must be changed frequently during the day. The herpetic eruption abates rapidly under this treatment. The element of pain is also subdued, and it is not rare to see rebellious neuralgias from herpes-zoster give way in a few hours to this treatment.

### ETHER AS A MENSTRUUM IN DILUTION OF THE SKIN.<sup>2</sup>

Dr. Sawyer considers that there are in practice three obstacles to the absorption of a medicine through the skin; namely, the epidermis, the sebaceous secretion of the skin, and the relative insolubility of the drug which is employed in any particular case. The ointment and oily liniments are a better vehicle for the

introduction of medicaments through the skin than plasters which have lead-plaster as a basis. After some observation and consideration, ether was thought the best menstruum at our disposal for the solution of many remedies designed for epidermic medication, and after examining a large number of drugs he has selected belladonna, iodine, menthol, and capsicum as suitable for external therapeutic employment in the form of etherial tinctures. He prefers to have the etherial tincture of belladonna made from belladonna root, with camphor, of the same strength as the belladonna liniment of the British Pharmacopœia, using the official pure ether in its preparation instead of rectified spirit of wine. To form an etherial tincture of menthol, after many experiments, a strength of one drachm to the ounce was fixed upon. The preparation can be readily applied as a paint to the skin, and is an efficient means of using menthol for its local therapeutic effects, especially for the removal of superficial neuralgic pain. It should be lightly painted over the painful part. The quick evaporation of the ether gives a grateful sense of coldness which supplements the analgesic action of the menthol, and allows the easy application of a succession of coats, which leave pure menthol in a finely divided condition upon the skin.

### TREATMENT OF DROPSY.<sup>3</sup>

At a meeting of the Society of Medicine in Berlin Dr. Furbring discussed the treatment of cardiac and renal dropsy. The fluid may be got rid of in four ways: (1) by the sweat glands; (2) by the kidneys; (3) by the intestines; (4) by surgical means. In cardiac dropsy diuretics hold the first place as does diaphoresis in dropsy of renal origin. In renal dropsy he used heat as a diaphoretic; the chief contra-indication is its employment is cardiac weakness with dyspnoea. Pilocarpine had been abandoned on account of the dangerous symptoms sometimes caused by it; among diuretics, digitalis is still the sovereign remedy, and it was of service also in renal dropsy and even in glomerulonephritis, for here cardiac debility often played a part. In cases in which he had failed to obtain benefit from digitalis either in the form of infusion, powder, or pill, he had obtained excellent results with acetum digitalis in combination with wine of pepsin.

Drugs such as adonis, convallamarin, blatta and sparteine are superfluous; they too often failed, and there were frequently unpleasant concomitant effects produced by their employment. With lactose he had had no success, but to the following he gives some commendation: strophanthus, caffeine, theobromine, calomel, and the group of saline diuretics. The action of caffeine on the central nervous system was disagreeable, but this might be avoided by the use of sodio-salicylate of theobromine, or diuretine.

When drastic purgatives are employed the patient should be strong and have a good pulse.

### TWO CASES OF POISONING FROM SMALL AMOUNTS OF ATROPINE.<sup>4</sup>

For a lad of twelve years Dr. Owens prescribed two or three drops of a solution containing two grains of atropine to the ounce of water to be instilled into the eyes three times within an hour on a Thursday morning, and again three times during that day, three times during Friday, and once on Saturday. Of these ten instillations the last two were omitted by his mother,

<sup>1</sup> *Journal of Medicine and Genito-Urinary Diseases*, No. 81, Jan. 1, 1891, p. 1390.

<sup>2</sup> *The Medical Press*, April 23, 1890.

<sup>3</sup> *Lancet*, vol. II, No. 9, 1890.

as the boy seemed strange on Friday afternoon. When seen by Dr. Owens on Saturday he had all the symptoms of atropine-poisoning, staggering, unsteady gait, dryness of throat and tongue, picking at imaginary objects, muttering, smiling, and occasionally laughing outright to himself. He could be aroused for a few moments so that he would answer questions, but soon relapsed. The face was slightly flushed, there was no rash, the pulse was small and rapid. Pupils were only moderately dilated, and responded but slightly to light. In a few days the patient was all right.

The second case was that of a remarkably healthy gentleman of seventy-three. In order to see if his cataract was mature, up to the periphery, two or three drops of a two-grain-to-the-ounce solution were instilled three times in about twenty minutes. The pupil dilated readily, but after finishing the examination he spoke thickly and did not answer questions readily. He got up to walk and fell back in the chair, and soon became almost unconscious. Paralysis was so complete that he was quite helpless, and had to be carried to the carriage, his face becoming suffused and the body covered with an erythematous rash; the pulse could scarcely be counted.

These cases are of interest, first for the small quantity of the drug that in each case produced such severe effects; secondly, the different toxic symptoms produced. In the old man's case paralysis came on rapidly and was complete, whereas in the younger patient the paralysis was less marked, the tetanic symptoms being most prominent, coming on eighteen hours after.

#### THE ACTION OF SALOL ON THE KIDNEYS.\*

This question has recently been investigated by Dr. Hesselbach, from both experimental and clinical standpoints, and the results have a very practical interest. Salol is a drug intended to take the place of quinine and salicylic acid, which was at first recommended as entirely free from noxious properties. Its drawbacks and dangers remained to be discovered by clinical observation. It was first prepared by Von Nencki in 1883, and was introduced into practice by Sahli in 1886. It is the phenylic ether of salicylic acid, and as is well known can be split up into components, phenol, or carbolic acid (some forty per cent.), and salicylic acid (some sixty per cent.), by the pancreatic juice, and to a less extent by the saliva, by the action of bacteria, by organic tissues, and by alkaline carbonates. These components are eliminated from the body, probably as phenyl-ether, sulphuric acid, and salicylic acid. Its decomposition and elimination from the body take place somewhat rapidly, for half an hour after the administration of thirty grains of salol salicylic acid can be detected in the urine; but the complete elimination of its components requires a much longer time. For days after its ingestion (in one case five days) the dark green or even blackish tint characteristic of carboluria is observable. The result of this slow excretion is that when salol is given continuously its components are apt to accumulate in the system, and give rise to medicinal and even toxic effects of an enduring kind. The action of salol is doubtless due entirely to the phenol and salicylic acid into which it is broken up, though Sahli surmises from the fat-like chemical character of salol, that in large doses it may be absorbed without decomposition. Even if this were so, however, it is by no means impossible that it would

be split up in the tissues if not in the alimentary canal.

There have been, too, opposing views in regard to the risk of using salol, but unquestionable carbolic poisoning has been reported as following the use of large doses, and Dr. Hesselbach gives details of a case which terminated fatally.

The patient was a servant, twenty-two years old, stout and somewhat anæmic, with no hereditary disease, and hitherto healthy, except for frequent headaches and swelling of the feet. On May 18, 1888, she was seized with acute articular rheumatism, for which she had salicylate of sodium, which relieved the pain except in the ankle. On June 8th she received 120 grains of salol within eight hours; she became unconscious and died on June 12th. On June 10th no urine having been passed since June 8th, eight and a half ounces of pale yellow, slightly turbid urine were drawn with a catheter, in this were detected traces of albumin, salicylic acid and phenol.

The chief changes discovered at the post-mortem examination, which are reported in detail, were in the kidney. The epithelial changes suggested strongly an acute exacerbation. Inasmuch as the dangerous symptoms which preceded death followed immediately on the ingestion of 120 grains of salol, it seems justifiable to infer that the case was one of salol poisoning, which led to the epithelial changes and ultimately proved fatal.

Why did the salol prove so exceptionally toxic, while in other cases it has shown itself innocuous? Is the salol chargeable with the toxic action, in particular the action on the kidney? Is it the phenol or the salicylic acid, or both of these? A series of experiments was instituted, beginning with an investigation as to the action of phenol on the kidney; this substance being the most apt to produce such changes, and was followed by an investigation of salol and salicylic acid.

The large number of cases of nephritis from carbolic acid which have now been put upon record, prove that the drug is a renal irritant. Although, therefore, there were already numerous data in existence pointing to the action of phenol on the kidney, it appeared necessary to have recourse to experiment in order to discover the way in which the action took place in one and the same species of animal and to compare the resulting microscopic preparations from different species. On examination after death there appeared hyperæmia and œdema of the pia-mater, anæmia of the kidneys, especially of the cortex, and fatty changes (degeneration) in the cortical tissues.

That phenol, apart from its cerebral effects, should chiefly attack the kidney is due to the fact that in this organ its transformation into the innocuous phenyl-ether sulphuric acid takes place. That this is so may be inferred from the analogous use of benzoic acid, which is changed into sulphuric acid within the kidney.

The excretion of phenol takes place through the epithelium of the convoluted tubes, and this is damaged in the process, then also its transformation into phenyl-ether sulphuric acid will at least be delayed and act as an irritant. Disease of the kidney, especially of the renal epithelium, must be unfavorable for the elimination of phenol and so constitutes a predisposition to toxic effects when the drug is administered and a contra-indication for its use.

\*Practitioner, Nos. 265, 266, 1890.

In the next series of experiments salol was administered to rabbits. The microscopic appearances were essentially the same as in those seen in phenol poisoning, everywhere the fatty degeneration of the epithelium of the convoluted tubules was unmistakable. That salicylic acid frequently gives rise to outward and dangerous symptoms, especially in relation to the central nervous system, is well known, its action on the kidneys has, however, been less frequently described. Chopin has found that in aged patients it readily gave rise to albuminuria, also in chronic renal disease it acted as a diuretic and increased the albuminuria.

After giving salicylic acid to rabbits the chief thing found in the kidneys on microscopical examination was the existence of hæmorrhagic extravasations in the interstitial tissue and the renal tubules, and not a destruction of the epithelial cells. Comparing, then, the renal changes produced by phenol and by salicylic acid respectively, the former, as we have seen, leads to anæmia of the kidney and acute fatty degeneration of the epithelium and of the convoluted tubules; the latter, to hyperæmia of the kidney and hæmorrhage into the interstitial tissue and the tubules, followed by comparatively slight epithelial degeneration. Phenol acts primarily on the cortex, attacking the medulla only when given in large doses; salicylic acid affects chiefly the medullary portions, and only when in large quantity extends its action to the cortex.

As regards the lethal doses the comparison is less precise, inasmuch as the mode of action of the two drugs is very different. Six grains of phenol (per pound) in five days proved fatal, while twenty grains of salicylate of sodium (per pound) were necessary to kill, and killed the animal in two days.

These observations appear to make it clear that the renal changes in salol poisoning are chiefly due to the phenol it contains. After the use of salol, anæmia of the kidney and acute fatty degeneration of the renal epithelium showed themselves; the cortex was the chief seat of the change, the medulla being but little affected, only when the dose of salol was large did distinct traces of hæmorrhage appear in the medulla and the medullary rays of the cortex. In other words, only after large doses of salol did the toxic effects of the contained salicylic acid become apparent.

But closer examination shows that the several morbid changes were by no means proportionate to the respective amounts of the two constituents of the salol, whence it may certainly be inferred that not the whole amount of these constituents were concerned in producing the toxic effects observed. Probably a considerable proportion of the salol is absorbed or eliminated unaltered. Which constituent is most potent in producing the symptoms of salol-poisoning is hard to determine with certainty, as the symptoms produced by the one are not unlike those produced by the other. But even in this respect the action of phenol seems to prevail.

In Dr. Hesselbach's patient the contraction of the kidney and the morbid changes in the secretory mechanism thereby induced, doubtless account for the fatal effect of the forty-seven grains of phenol contained in the salol ingested. Phenol-poisoning may occur much more readily if the renal epithelium is already diseased than if the kidney are sound. Further, Kuster has observed that phenol, and therefore, salol, is especially toxic to anæmic or feeble patients of the female sex,

and the death of this patient becomes thus more intelligible.

The following are Dr. Hesselbach's conclusions: (1) The large proportion of phenol contained in salol renders it so toxic a substance that its unrestricted therapeutic use is fraught with danger. (2) In renal disease, acute or chronic, salol is contraindicated.

#### TREATMENT OF SOME URINARY DISORDERS.<sup>6</sup>

In comparing the various systems of which the human body is built up, such, for instance, as the nervous, respiratory, circulatory, digestive and urinary, the last especially enjoys a condition for the action of drugs which is not equally shared by the other systems, except, perhaps, the digestive system.

Dr. Reginald Harrison devotes a part of a clinical lecture to a consideration of the uses of certain drugs in urinary disorders.

The power of quinine in connection with operations on the urinary organs has long been recognized, and there can be little doubt that this is directly associated with the fact, that it is so largely eliminated by the urine.

Dr. Palmer, of Louisville, Ky., found that he could so sterilize the urine by the administration of boracic acid in ten-grain doses as to prevent the occurrence of urethral fever after such operations on the urethra as internal urethrotomy. The power of sterilizing the urine so as to render it innocuous when placed under conditions where otherwise it would be liable to generate septic influences, is not limited to boracic acid and quinine. Hypophosphate of soda in half-drachm doses, in some purulent affections of the urinary organs may owe its beneficial effects to its influence as a bactericide.

Dr. Harrison has used pichi during four years in the form of a fluid extract, in drachm doses, with considerable benefit. In renal colic and the passing of calculi through the kidneys and along the ureters, attended with hæmaturia; though not exercising any solvent power, it seems by its action on the tissues in some way to favor the escape of the stone, and thus suppress bleeding; it has been found useful also in the hæmorrhage which frequently accompanies cancer of the bladder. The sedative action of the drug on the mucous membrane of the bladder has proved beneficial in many instances of irritability connected with a large prostate. After the bladder has been properly cleansed by irrigation and disinfected, it has been frequently found that the calls to urinate were far less urgent when the pichi was being used.

Acting somewhat similarly, though less astringent in its properties and, therefore, of less value when there is hæmorrhage, is an extract prepared from the berries and fruit of the raw palmetto (*serenoa serulata*); it seems to act something like pareira, and is a good substitute for it.

Of the chemical products, saccharin in half-grain doses is useful in preventing the ammoniacal change in the urine in cases of cystitis, where the mucous membrane of the bladder throws off large quantities of mucus, and the urine undergoes rapid ammoniacal decomposition, the urine may become healthy and acid under the use of saccharin, and on discontinuing the drug, the urine will speedily return to its original condition. Hence, it may be found useful in readily providing against conditions which cannot be radically

<sup>6</sup> The Medical Press, No. 2,671, 1890.

altered. Dr. Thomas Stephenson and Dr. Woolridge have shown that saccharin may be taken for a considerable period without interfering with the digestive or other functions of the body. Another chemical product is borocitrate of magnesia, prepared by dissolving a natural borate of magnesia, found at Strassfurt, in citric acid. It forms a white powder with a sourish taste, and is given in teaspoonful doses in a tumbler of warm water two or three times a day. Its employment has been advocated by Dr. Kochler, in cases of uric acid calculi and gravel. The discharge of these bodies, whose presence has previously been suspected, has frequently taken place after the use of this salt. It may be, all it does is to secure that the individual shall take at stated times more fluid than perhaps he would otherwise do; an important point, upon which Sir William Roberts has laid stress. Dr. Harrison is disposed to think that it does more than thus induce a person to flush his kidneys with a bland fluid, by no means disagreeable to taste, and that it is capable of modifying or altering the crystalline form in which uric acid is discharged, and of exercising a solvent power on some kinds of urate stones.

#### NEW METHODS OF TREATING ERYSIPELAS.<sup>7</sup>

Rosenbach's method consists in washing not only the erysipelatous patch, but the entire neighboring surface, with soap and then bathing daily these patches with five per cent. solution of phenic acid dissolved in absolute alcohol. Very brilliant results are claimed to follow this method, both as regards the course of the disease and the febrile phenomena. Even absolute alcohol is said to produce a favorable action.

In Nolte's method the entire affected surface and surrounding zone are painted twice daily with a mucilage of gum-arabic containing from three to five per cent. of phenic acid.

The method of Koch consists in applying by means of a camel's-hair pencil, the following ointment in a thin layer over the affected parts:

Crocin . . . . .	1 part.
Iodoform . . . . .	4 parts.
Lanolin . . . . .	10 parts.

After the ointment is applied it is covered with a thin layer of gutta-percha. This method is said to be especially applicable to erysipelas of the face and of the hairy scalp.

In the method of treatment of Nussbaum and Brumen, ichthyol is employed in collodion.

Hallepeau recommends the use of a solution of one part to twenty of salicylate sodium. Thick cloths are wet with this solution, then applied to the affected parts, and then covered with a layer of rubber cloth so as to prevent evaporation. Almost immediate relief is obtained, and a cure is said to follow on the third to the fifth day.

Hunter recommends the injection of carbolic acid into the healthy skin at a distance from the part infected. This method of treatment is extremely painful, and is only applicable in severe cases of the face or hairy scalp.

Dr. Kraske advises making an incision in the healthy skin around the erysipelatous patch before applying the antiseptic substance.

Wöfler makes use of mechanical compression by bandages applied so as to circumscribe the inflamed tissue, while Dr. Kraske proposes elastic rubber bands

to accomplish the same effect, where these are applicable.

#### DEATH FROM A LARGE DOSE OF PARALDEHYDE.<sup>8</sup>

Bridget O'B., twenty years old, was admitted to the fever hospital attached to the Cork workhouse, suffering from typhoid fever. Through an oversight on the part of the attendant, she was probably given six or seven drachms of paraldehyde. In about five minutes she fell into an unconscious state, and, despite medical assistance, she died some hours later.

#### ARISTOL.

(1) Aristol has been used in a pure state in sclerotic and other ulcerations in the male and female genitals. After washing the ulcers with carbolic or sublimate water, the aristol was powdered on and covered with gauze. In ulcers on the glans penis it is necessary to remove the bandage frequently on account of priapism; in those cases iodoform has the advantage over aristol. In syphilitic and indolent ulcers or chancres, the latter acts exceedingly well. Great cleanliness is necessary, especially about the female genitals. In fresh cases aristol has no advantage over iodoform.

(2) Aristol was made use of with the best results in acute otitis media and otorrhoea in place of boracic acid, in lupus laryngis, laryngorrhoea, in ulcerations of the penis, and ulcers of the leg. In burns aristol (with oil or lanolin, ten per cent.) relieved pain and caused rapid cure.

Aristol possesses the advantages of iodoform and can even be used in children, with whom iodoform must be used carefully.

Aristol has not a penetrating odor like iodoform.

### Clinical Department.

#### TWO CASES OF LAPAROTOMY FOR PELVIC ABSCESS, WITH PERFORATION OF THE INTESTINE, AND CONTINUOUS PURULENT DISCHARGES.

BY ERNEST W. CUSHING, M.D.

I HAVE the honor to present to your Society to-night two specimens which illustrate a class of cases, the most difficult and dangerous of all the results of pelvic inflammation, which can be dealt with surgically. I refer to cases where suppuration in and around the uterine appendages has found an exit through the intestine, through which the pus is continually discharged, although the suppurating sac or tube never ceases to secrete a fresh supply, so that the unhappy patient wastes miserably, and succumbs at length from the well-known effects of prolonged suppuration.

I desire to call particular attention to such cases, because in many text-books the discharge of a so-called pelvic abscess through the rectum or bladder is spoken of as a sort of natural and almost favorable termination of the disease, whereas, in point of fact, it is almost always a lamentable and miserable failure on the part of nature to cure the disorder, and at the present time must usually imply that there has been a

<sup>7</sup> Read by invitation before the Obstetrical Society of Boston, December, 1890.

<sup>8</sup> Lancet, August 29, 1890.

<sup>7</sup> Therapeutic Gazette, No. 16, 1890.

want on the part of the attendant physician either of a due comprehension of the nature and gravity of the original pelvic inflammation, or a lack of diligence in securing a proper evacuation of the pus, and removal of the diseased appendages by abdominal section. The change of opinion in regard to the pathology of pelvic inflammation has been so striking within the last few years that it is not to be wondered at that these neglected cases continue to occur, and, owing to many circumstances which are quite beyond the control of family physicians, it is clear that a certain number of women will always continue to be unable to obtain, or will refuse the opportunity of receiving timely surgical interference, so that in order to be finally saved they must undergo an operation much more critical and difficult than the removal of the seat of disease by a seasonable laparotomy would have been.

The number of such operations, where a perforation of a bowel exists already, which have been reported is, however, so limited that no rules have been established for the technique of the operation, and I submit these two cases to the attention of this Society, hoping that the experience of some of the members may serve as a basis for a discussion as to the proper means of treating such formidable complications.

CASE I. Mrs. McL., patient of Dr. Coffee, of West Fairlee, Vt., applied for admission to the Woman's Charity Club Hospital, December 1, 1890, with the following history: She had been suffering from some pelvic disease since she was nineteen years of age, when she broke down at school, and was treated with tampons and pessary. Since that time she has had great trouble at her menstrual periods, and has never regained her health fully. Has been married for several years, but has never conceived; is now thirty-one years of age. Six years ago she went to bed for a long period, and had several severe uterine hemorrhages; she was treated with tampons for enlargement of the uterus. Had an attack of peritonitis about the middle of last October, and had been confined to her bed for about six weeks before that; has gradually recovered sufficiently to be transported to the hospital.

On admission, the diagnosis of discharge of pus from the intestine was immediately made, from the characteristic odor and appearance of the discharges. On examination I found what appeared to be a small fibroid tumor much obscured by rigidity of the abdominal walls and of the vaginal roof, with evidence of the presence of a mass in the left iliac fossa. The patient was emaciated and cachectic; although I greatly feared that there might be a complication with malignant disease, I determined to give the patient the benefit of an operation.

On opening the abdomen the enlargement of the uterus was found to be a common myoma; both tubes were the seat of pyosalpinx; and on the left there was a considerable abscess cavity, which communicated with the colon at a point near the middle of the sigmoid flexure. No attempt was made to remove the myoma; but the uterine appendages, and the sac of the abscess, were enucleated carefully, tied close to the corium of the uterus, and removed. The connection between the tube and the colon was separated as gently as possible; the opening in the bowel, which was about one inch long, was trimmed and refreshed with sponges, and then the muscular and mucous coats were united with a continuous suture of fine silk, over

which was another continuous sero-serous suture, bringing peritoneal surfaces together; careful irrigation and a glass drainage-tube completed the operation. Recovery was uneventful; no fecal matter escaped through the tube, although a little gas passed off at times through the opening, after the tube had been removed. This finally closed, however. The tumor seems to be somewhat smaller than before the operation, and gives no trouble.<sup>2</sup>

CASE II. Mrs. B., aged forty, was sent to me at the hospital by Dr. Greene, of Bethel, Vt., in May 1890, with the following history: For fourteen years she had been a sufferer from uterine disorder, and during the last three years there had been repeated attacks of pelvic inflammation. In September, 1889, an attack more severe than usual occurred, when an abscess formed and ruptured into the rectum high up. Through the latter there had been a continual discharge of very offensive pus, which was so profuse that the strength of the patient was failing and she was slowly sinking. Under these circumstances her physician sent her to the hospital, feeling that the source of this waste, which could not be controlled through the rectum, in spite of careful attempts at disinfection and drainage, must be found and remedied by surgical measures. Examination showed masses in the region of the tubes, both of which were evidently affected. The discharge of pus was horribly offensive, and the condition being desperate, I concluded to perform laparotomy.

At the operation one pus tube was removed without much difficulty; but on the left both tube and ovary were involved in a large abscess, the wall of which was densely adherent to the intestines and to the surrounding parts. After isolating the upper part of the large sac it was opened, when gas and pus, mingled with feces, escaped. The cavity of the abscess was now carefully irrigated with a strong solution of sulpho-naphthol, the patient being turned on her side, and care being taken to allow as little of the fluid as possible to escape into the abdominal cavity. I was strongly tempted to sew the sac into the abdominal wound, but concluded that the fecal fistula certain to result from this course would leave the patient little better off than before. I therefore carefully enucleated the whole sac, separating it from its connection with the intestine with as little violence as possible. Dr. Greene now passed his finger into the rectum so that it emerged through the rent in the latter, and I was able to feel the finger, and with a Sims' speculum to see it, in the pelvis. The edges of the opening in the intestine were caught with pressure forceps and carefully drawn up, and the opening closed with eight fine silk stitches and a continuous suture of catgut. Irrigation; glass drainage-tube; recovery, with fecal fistula, which closed entirely within a month, so that the patient went home well, and has remained in good health now for seven months.

NAME OF KOCH'S FLUID. — The new supply of Koch's lymph is sent out in bottles labelled, "Tuberculin, Dr. Libbertz," so that, after having had all sorts of names, such as "Kochin," "Koch's fluid," etc., bestowed on it by amateur godfathers, the lymph may now be considered officially christened.

<sup>2</sup> Patient has left the hospital very much improved in health, and apparently cured of the pelvic inflammation.

## Reports of Societies.

### THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.<sup>1</sup>

#### MIGRAINE AND HEADACHE FROM EYE-STRAIN.

THE point made by DR. P. CALLAN was that eye-strain was responsible in seventy-five per cent. of the cases for functional headache and migraine.

#### ONE THOUSAND CASES OF OCULAR HEADACHE, AND THE DIFFERENT STATES OF REFRACTION CONNECTED THEREWITH.

DR. W. F. MITTENDORF said that Dr. Roosa had anticipated the points which he had endeavored to emphasize in the paper which he had prepared. He believed that the treatment of a large majority of these eye cases should be directed to the improvement of the hygienic surroundings of the patients. Of the thousand cases of headache which he had observed and tabulated, only a fractional portion could be set down as the result of muscular insufficiencies directly.

#### SOME POINTS ON THE PATHOGENESIS OF AURAL VERTIGO.

THIS was the title of a communication by DR. O. D. POMEROY, of New York. He had deduced from the cases which had come under his immediate observation, that vertigo was the direct result of a variety of causes and among these he enumerated suppuration of the middle ear, labyrinthine disease from traumatism, sunken drum membrane in acute and chronic middle catarrh, sclerosis of the middle ear, Ménière's disease, polypi, and syphilis. Of late, operative procedures had been instituted for the relief of the conditions which caused pressure upon the peri-lymph and consequent vertigo. This consisted in a division of the tensor tympani of the stapedius perforation of the membrane and so forth, but with little effect. More recently still the membrane itself, with one or more of the ossicles, had been removed with the hope of relieving sources of pressure or obstruction to the passage of audible tones, but so far, with uncertain results. In reviewing the work of neurologists it was apparent enough that diseases of the internal ear figured principally as pathogenic factors in vertigo. This the speaker believed to be a conspicuous error, as in his experience, at least, a much larger number of cases of middle ear disease were concerned in the causation of vertigo than were those of the labyrinth. He had thought it proper to develop this subject from the fact that vertigo had often been regarded as evidence of brain or spinal disease when an investigation of the auditory apparatus might have placed the difficulty elsewhere.

#### APPENDICITIS.

THE importance which is now attached to inflammatory disturbances in the region of the appendix vermiformis from a medical and surgical standpoint was well demonstrated by the fact that an entire evening session was devoted to what proved to be a brilliant and exhaustive consideration of this subject. It is impossible in this writing to attempt more than the most superficial *résumé* of the points brought out by the several speakers.

DR. HERMAN MYNTER, of Buffalo, to whom had

<sup>1</sup> Eighty-fifth Annual Meeting, held at Albany, February 3-5, 1891. Continued from page 189 of the Journal.

been assigned the expounding of the gross pathology of the disease, said that he had followed in this respect the nomenclature of Professor With of Copenhagen, who had described three forms of appendicitis: (1) Peritonitis appendicularis adhesiva, in which the ulceration in the appendix went so deep that the peritoneal covering was affected and adhesions were formed; (2) peritonitis appendicularis localis, characterized by local peritonitis and abscess; (3) peritonitis appendicularis universalis, in which there was diffuse peritonitis by perforation into the peritoneal cavity. The question as to whether abscesses which formed were intra- or extra-peritoneal had been much debated. He saw no reason for any disagreement upon this point. Both the cæcum and the appendix were, according to Bull and others, always completely invested by peritoneum. An abscess starting in the appendix must necessarily at the onset be intra-peritoneal, limited by adhesions. If the adhesions were strong, and exudation continued to be deposited so that the perforation into the abdominal cavity was prevented, the parietal peritoneum might become perforated, and the pus was then in the retro-peritoneal tissue, that is, in the iliac fossa, and constituted an extra-peritoneal abscess, and if not opened by an extra-peritoneal incision above Poupart's ligament might perforate elsewhere, as, for instance, into the rectum, the ischio-rectal fossa, or backwards.

DR. A. P. GERSTER, continuing the subject of the pathology, said that in a majority of cases of perforation of the appendix, the cause was to be found in stenosis or atresia of some portion of the organ. Then there were perforations which occurred without such condition being present, as, for instance, from tuberculous ulceration, typhoid fever, and so on. It had been thought that foreign bodies had played a very important part in producing perforation, but he believed that, taking into consideration the large quantity of such bodies which were constantly swallowed in the food, that perforation ought under such circumstances to be much more frequent than it was. The appendix, having a muscular coat, had the power of expelling bodies which might be caught in its blind sac. He thought that this view was proven by the fact that in a vast proportion of cases of perforative and non-perforative appendicitis foreign bodies were not present at all. The most common cause of the trouble was a catarrhal condition which either took origin in the appendix itself, or was continued or transmitted from the *caput coli* into the appendix. The latter seemed to the speaker the most common process.

DR. CHARLES McBURNEY then gave an elaborate review of his own practical experience in treating the disease surgically, and the deductions which he had drawn therefrom as to the indications for early laparotomy. He emphasized the fact that the earliest possible diagnosis and frequent examination of the patient, might properly be demanded of every physician and surgeon who was called to attend a case of appendicitis. Clearly defined rules which would guide safely in all instances to a decision as to when a case of appendicitis might be safely treated conservatively, could not be laid down. A general description often, but not always, applicable was the best substitute he could offer. The diagnosis having been made in a given case, the treatment should be directed to ensuring absolute rest and controlling peri- and retro-peristalsis. As a local application over the cæcum and appendix, cold was by far the best. Anodynes should not be given to the

point of masking the symptoms, and were possibly better avoided altogether. If nausea disappeared within twelve hours, if at the end of the same period tenderness on pressure had not increased, if the temperature remained normal or had not risen to 100° in the mouth, if the pulse was not accelerated or but slightly so, and if the patient moved in bed with ease, the case was probably a mild one destined to recovery. If at the end of twelve hours more this state of things still obtained, the chance of favorable ending was enhanced. If during the succeeding two days no tumor had formed and the symptoms had all improved or some had improved while others had remained stationary, the case might be considered as practically safe, although complete rest should be enjoined. Again, in other cases the temperature would be higher, the pulse full and the nausea considerable; still these symptoms might not increase in severity, and the indications for conservative treatment would be clear. In these latter cases a short interval of twelve hours or more would usually develop signs of improvement, or of the cessation of advance, or of the advance of the symptoms. If signs of improvement had appeared, medical treatment would be continued. If the symptoms had merely ceased to advance, the decision would be postponed till another visit, to be made after a short interval, the medical treatment being in the meanwhile continued. If the symptoms had become more marked, then the question of immediate operation arose. In all of those cases which showed well-marked signs of increasing disease the question of an operation should be deliberately and carefully discussed, and in the opinion of the speaker the operation should be done. It was not best to wait strong evidence of perforation or peritonitis. It was not satisfactory to wait till the pulse became rapid and weak, and the respiration anxious. No one could name the signs of impending perforation. When spreading peritonitis was discoverable, the peritonitis had already spread. If the peritonitis had passed beyond the wall of an abscess, then the abscess had already ruptured. If marked distention of the abdomen was waited for, section might demonstrate septic paresis of the gut, a condition from which the speaker had never known a patient to recover. Such indications were conditions which it would be wiser to anticipate. It might be laid down as a rule with few exceptions that the indications of advancing disease could be clearly made out by the end of thirty-six hours, provided that the diagnosis had been made early, and followed up by several careful examinations. Advancing disease, with significant symptoms, at this period offered the necessary indications for operation. The speaker then more minutely considered the various symptoms, both subtle and pronounced, which should be observed by physician and surgeon as bearing upon the important question of operative interference.

DR. W. W. KEES, of Philadelphia, continued the discussion of the foregoing question under five heads: (1) Appendicitis of a mild form, without formation of abscess and terminating in resolution. (2) Perforative appendicitis followed by general peritonitis. This class he divided into severe, early, fulminating peritonitis, and an apparently mild peritonitis suddenly bursting out into general peritonitis from perforation of the appendix or rupture of an abscess. (3) Cases of abscess-formation in which evacuation of the pus was effected either by operation, external rupture or rupture into a hollow viscus. In these cases resolution or death usu-

ally took place in from three to four weeks. (4) Abscess-formation took place slowly, the chronicity continuing for weeks or months or even a year before discharge took place. (5) Cases of recurrent appendicitis. The speaker was of the opinion that of the milder forms examination would demonstrate that about one-third of all adults had been affected by one or more attacks. The position taken by Dr. Keen was substantially that of the previous speaker, that conservative measures were admissible only up to a certain point, beyond which operative procedures offered most encouraging results, the prospects diminishing in proportion to the delay.

DR. L. A. STRIMSON, of New York, in considering the technique of operations for the relief of appendicitis, divided these into two groups: those in which the general peritoneal cavity was opened with the intention of removing the appendix, and those in which the interference was limited to the evacuation of the abscess without exposure of the general cavity. For the first he recommended a lateral incision along the border of the right rectus. In the search for the appendix the anterior longitudinal bundle of unstriated muscle of the colon was a guide, for it ran directly to the appendix. To secure the stump of the appendix he preferred a stout catgut ligature to enfolding and suturing the end. He urged the employment of a drainage-tube and an abundant packing of iodoform gauze whenever pus was found and there had been prolonged exposure and handling of the intestines. He thought the use of these made it safe to empty and drain through the incision abscesses that were not adherent to the anterior abdominal wall. He did not advocate free irrigation of the general peritoneal cavity, as he considered it inefficient for disinfection and possibly harmful. For the second class of operations he recommended the usual oblique incision parallel to the upper part of Poupart's ligament, opening directly into the abscess if it were adherent in the line of the incision, or passing backward between the peritoneum and the iliac fascia, to reach the abscess from behind near the base of the appendix if it were small and not adherent in front. Abscesses deep in the pelvis could be operated upon through the anterior wall of the rectum by guiding the knife on the finger after stretching the sphincter.

DR. ROBERT F. WEIR, of New York, gave his conclusions as to the propriety of and the indications for resection of the appendix during the quiescent stage of chronic relapsing appendicitis. A year ago he had expressed the opinion that when the recurrent attacks of appendical inflammation were so frequent as to impair the patient's usefulness in life, it was proper to run the risk of a laparotomy for relief, but that this measure might be delayed until an acute attack was in progress. Careful deductions made from twenty-four cases had induced him to concur in the opinion that, in the absence of definite contraindications, intermediate laparotomy might be performed in cases where the patients were debared from the enjoyment of life or the ability to earn a living. He was led to indorse this view from the uncertainty of attaining a proper discrimination in diagnosis, from the slight mortality in the quiescent stage, and the usually uniform good results which were obtained.

DR. ALBERT VANDER VEER, of Albany, considered the relation of the physician and surgeon in the care of cases of appendicitis. He thought that the care of

such cases, so far as the physician was concerned consisted in an early recognition of the disease, and that then, in view of the present success of abdominal surgery in these cases, it became his duty promptly to share the anxiety of the case with the operating surgeon. There existed no longer any excuse for a physician in full practice who pleaded ignorance of "the McBurney point." Upon the surgeon, after being called into consultation, there would rest much of the subsequent responsibility, though both physician and surgeon should associate in watching the case. If the care of appendicitis could be upon the basis thus suggested, fewer cases would come to the operating table in a septic condition seeking the surgeon's aid only as a forlorn hope.

DR. FRANCIS BACON, of New Haven, said that the expectant plan which he had so far adopted might be regarded by some as unjustifiable temerity. He narrated a case in which he had operated with cocaine anæsthesia and in which an interesting point had been observed. When the appendix was exposed and during a moment of sensitiveness handling of the organ had caused the patient to complain of pain in the region of the umbilicus.

#### PELVIC INFLAMMATION IN WOMEN.

This formed the subject of a series of papers and discussions.

DR. A. F. CURRIER, of New York, introduced the subject. He said that the practical points which were to be explained, were whether pelvic inflammations in women, were due to traumatism or infection or both. Also, what was the influence of parturition, gonorrhœa, syphilis, surgical injuries to the pelvic structures, the congestion of menstruation, retained secretions within the uterus or vagina, and solid and cystic new growths. Blood and lymph vessels and glands, nerves, muscular and cellular tissue, serous and mucous membrane were all present in the pelvis, and were all susceptible of inflammatory processes. The uterine appendages might undergo varying degrees of inflammation and degeneration; as to the methods of dealing with the various morbid processes, he would leave that part of the discussion to the gentlemen who followed him.

DR. W. GILL WYLIE, of New York, in dealing with the question of the pathology of inflammation of the uterine appendages and tissues around the uterus said, that when in a state of acute inflammation it was very difficult to make a differential diagnosis as to the location of the inflammation in many cases. During the acute stage of septic poisoning after labor, or abortion, there was inflammation of the veins and lymphatics, but phlegmon was rarely formed in cellular tissue. The poison might extend in the cellular tissue and an acute cellulitis kill the patient, but such a condition as a chronic cellulitis the speaker had never seen. When removing diseased Fallopian tubes and ovaries during the acute stage of the formation of a pelvic abscess he had found the connective tissue of the broad ligament oedematous and thickened. Here the real disease was in the tube and ovary and the connective tissue was only affected by continuity, for when the tube and ovary were removed the oedema in the surrounding tissue would soon disappear.

In over four hundred laparotomies done for the removal of diseased tubes and ovaries, the great majority being typical cases of so-called cellulitis, the speaker had not found one case which could be fairly termed

cellulitis. Invariably the abscess had started in or about the Fallopian tube or ovary within the peritoneum.

(To be continued.)

#### THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MEETING, December 13, 1890.

DR. DRAPER referred to the death of Dr. Doe, and moved that a committee of three be appointed by the Chair to draft resolutions on his death. The Chair appointed Dr. Draper, Dr. Blake and Dr. C. E. Stedman. The resolutions were printed in the December 18th number of the JOURNAL.

DR. TOWNSEND reported a case of pregnancy at an advanced age; and showed the patient and her child. (Publication reserved for a later date.)

DR. BLAKE spoke of a woman he had attended, who was forty-seven years old when she had her first child. Another patient gave birth to a child at the age of fifty-five years.

DR. RICHARDSON knew of an authentic case where the patient had her first and only child at the age of fifty-two years.

DR. SINCLAIR knew of two sisters who menstruated up to the age of fifty-six and sixty years respectively, and said that pregnancy was probably possible throughout the period of menstruation.

DR. TOWNSEND said that ovulation might continue after menstruation had ceased, and cited a case which he had seen reported of a woman who gave birth to a living child eighteen months after the cessation of menstruation, and he had himself attended a patient a few days ago, who, at the age of forty-three, gave birth to a living child eleven months after the catamenia had ceased; she had supposed it was the change of life.

DR. SINCLAIR knew of a similar case where confinement took place twelve months after the cessation of menses.

DR. EDWARD REYNOLDS read a paper  
ON THE EXTRACTION OF THE AFTER-COMING HEAD  
AND ARMS.<sup>1</sup>

DR. W. L. RICHARDSON said that he had found great help in delivering the head in such cases by attempting to first push back the head a little, one hand being behind the occiput and the two fingers of the other resting on either side of the nose, while at the same time the head is flexed as much as possible. By so doing a more perfect flexion is obtained. With the head at the superior strait it will be often found easy to deliver if the forceps are applied directly over the occiput and face. Formerly it was thought that forceps so applied would increase the bi-parietal diameter. Experiments have, however, shown such not to be the case—the effect produced being a telescoping of the head.

DR. GREEN said that in an article by Winckel, some twenty-nine different methods were described for delivering the after-coming head, all of which could probably be reduced to two or three good methods. Martin's (Winckel's) method consists in using the right hand for supra pubic pressure, the finger of the left hand being placed in the canine fossa.

<sup>1</sup> See page 205 of the Journal.

a method which would require the operator to be of more than average strength. It is undoubtedly a matter of personal experience, and each operator prefers his own way.

Dr. Green depends largely on the intelligent suprapubic pressure of an assistant, and believes it is always well to have a medical man for an assistant in these cases.

As to the use of forceps, he believed it to be a matter of personal equation, as the reader said, and for his own part he prefers manual extraction to this instrument. He had occasionally failed with forceps where he had afterwards succeeded with the hands.

Dr. TOWNSEND said that he had found the forceps most serviceable in the delivery of the after-coming head, and he believed that in difficult cases it was a much easier and more scientific way of delivery than the methods of manual extraction. He had been particularly fortunate in their use, and recalled especially one case which he had already reported to the Society where delivery by the Prague and Snellie-Veit methods failed, where forceps alone failed, but the quick application and use of axis traction brought out a living child.

In all cases where vigorous use of manual methods fail, he always uses, without delay, the forceps, and it may be owing to this fact that he regards them so favorably.

Dr. E. REYNOLDS said that this was probably the fact that those who use forceps early are the ones who are most impressed in their favor, and quoted a remark of Godell that he has lately learned to use more force in the manual extraction of the after-coming head, and has had less need of forceps.

Dr. RICHARDSON said that he always resorted to the forceps without delay if he was unsuccessful in the use of the manual methods. He did not believe in prolonged efforts at manual extraction.

Dr. E. W. CUSHING reported by invitation

TWO CASES OF LAPAROTOMY FOR TUBAL DISEASE,<sup>2</sup> and showed specimens.

Dr. BAKER said that this class of cases is both interesting and trying to manage, and it is to be noted that they have apparently increased in frequency lately, owing to the fact that they are now properly diagnosed, whereas they were formerly supposed to be cases of pelvic cellulitis.

It is a question whether they can be best treated by laparotomy or by an opening with drainage tube into the rectum. Undoubtedly, where the tube can be removed and the opening closed, as in Dr. Cushing's cases, this is certainly the best and quickest procedure, but many operators would not be so successful. The method of drainage into the rectum is, perhaps, therefore, the safest and best, especially if the opening be within easy reach.

Dr. CUSHING said that this would have been impossible in the first case, as the opening was high up in the sigmoid flexure, and there was a fibroid in the way.

Dr. CHILVER said that cases of pelvic abscess which open spontaneously into the rectum, generally get well. He had seen a case which was opened anteriorly, but which was not cured until it opened itself into the rectum.

Dr. BAKER said that the cases of pelvic abscess

which used formerly to waste to death with old discharging sinuses are not seen now in these days of laparotomy.

It was voted that copies of the resolutions on Dr. Doe's death be placed in the records, be published in the *Boston Medical and Surgical Journal*<sup>3</sup> and be sent to the family of the deceased.

## NEW YORK MEDICO-LEGAL SOCIETY.

At a meeting of the Medico-Legal Society held February 11th, there was a discussion of the report of a special committee on

### HYPNOTISM,

in which certain questions were suggested for consideration, such as the following: Is hypnosis a disease? Is hypnotism attended with danger to the subject? Should hypnotism be used on criminals in an inquisitorial way? Should the Penal Code be amended, and the rules of evidence be changed to admit hypnotism as an element in court proceedings?

The first speaker was Dr. E. P. THWING, who took the ground that hypnosis was not as a rule dangerous to the subject. He had made about one hundred and fifty experiments, and no unsatisfactory results had followed any of them. Like other useful agents, however, hypnotism was liable to abuse, and he had heard of instances where serious results had followed such abuse of it. The employment of hypnotism in courts of law, in an inquisitorial way, to get accused persons to incriminate themselves, he believed would be improper and illegal.

A number of letters from authorities in different cities were read. Among them was one from Prof. WILLIAM JAMES, of Harvard, in which he strongly opposed the idea of using hypnotism inquisitorially, and also objected to having any legal rules laid down for the regulation of hypnotic experiments when conducted by scientific men of good professional standing.

Dr. CHARLES H. HUGHES, of St. Louis, wrote that under certain well-defined restrictions he thought that hypnotism could be used inquisitorially without either impropriety or injustice. He believed that public exhibitions of hypnotism should be prohibited by law. Hypnosis, he said, was an abnormal and unnatural function of the brain, and the practice of inducing it should not be encouraged where the subjects were persons of great impressibility.

Prof. GEORGE TRUMBULL LADD, of Chicago, expressed the opinion that hypnotism had not reached such a stage in either the general understanding or the scientific world as to call for any changes in the civil or criminal law. It might, for the time being, at least, properly be left in the control of science. The law, however, should prohibit public exhibitions of hypnotic subjects, and should prevent the practice of hypnotism by incompetent persons.

Among those who took part in the discussion were Dr. PAUL GIBICK and Mr. JULIAN HAWTHORNE. The latter believed that on certain occasions individuals become self-hypnotized, and the greatest achievements of orators, actors and poets were sometimes made in this state.

## Recent Literature.

*Du Chemisme Stomacal (Digestion Normal Dyspepsie).*  
By Drs. G. HAYEM and J. WINTER. Pages 274.  
Paris: G. Masson, Publisher. 1891.

This book contains some exceedingly important new researches on the gastric juice in health and in disease. It is divided into two parts: I, The Normal Chemistry of the Gastric Juice; II, The Pathological Chemistry of the Stomach.

The writers reject the terms *hyperacidity* and *hypoacidity*, so much in use by the German authorities to designate two most common causes of dyspepsia and present as their classification three principal categories: *hyperpepsia*, *simple dyspepsia* and *hypoepsia*. The latter may end in complete *apepsia*.

Hyperpepsia is characterized by exaggeration of the normal fermentative processes; there is in the ordinary quantitative type augmentation of the free hydrochloric acid and of the chloro-organic compounds. But often the fermentative process, abnormally exaggerated, is, at the same time, deviated from its ordinary evolution, and the hyperpepsia becomes *qualitative*.

Hypoepsia signifies enfeeblement of the gastric fermentative processes. In the most common form there is deficiency of chlorides, deficiency of HCl, without notable qualitative deviation, without acid fermentation. Nearly all patients with hypoepsia in the first degree have been neuropathic; among the gastric lesions, dilatation of the stomach has been most frequently noted.

Apepsia is characterized by suppression of the stomachal chemical function. There is complete absence of HCl, free or combined.

In simple dyspepsia the patients complain of more or less pronounced digestive troubles, while the stomachal chemism is found to be absolutely normal or nearly so. The dyspepsia is generally constituted by an enfeeblement of the motricity of the stomach, or by phenomena of a purely nervous nature.

Such is the briefest possible analysis of a book which is destined to mark an epoch in the progress of stomachal pathology. The work is not easy reading, and fairly bristles with mathematical formulae, which, at first sight, remind one of a treatise on eye diseases.

Thus, on page 209, we find a clinical account of a case of hypoepsia with dilatation of the stomach and symptoms of neurasthenia. The condition of the gastric function is indicated by the following formula:

$$\begin{array}{lll} T = 0.335, & H = 0.110 & A = 0.120, \\ T = 0.166, & C = 0.129 & a = 0.022. \end{array}$$

He who is an enthusiast in gastric pathology will master both the formulae and the methods, and will be able henceforth to bring mathematical exactness into the work of clinical investigation.

The careful perusal of this book leaves in our mind a rather painful impression of the complexity of the pathological states of the stomach and the difficulty of diagnosis. Such qualitative and quantitative estimate of the dyspepsias as is set forth in this work necessitates repeated test experiments, "soundings" of the stomach and analyses of its contents, for which a special laboratory training, or the constant presence of a competent chemist is demanded; there are hints, too, as to possibilities in the direction of fearfully enhanced responsibilities on the part of the gastropathic expert of the future who must (if true to his calling), leave neglected none of these means of diagnosis which exact science has placed in his hands.

E. V. H.

THE BOSTON

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 26, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.56 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DANRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

## LEGISLATION CONCERNING ARSENIC.

A PETITION has recently been presented in the Massachusetts Legislature and referred to the Committee on Public Health, asking for legislation to forbid the manufacture and sale of paper hangings and fabrics containing arsenical pigments. The subject is not a new one. Attention has repeatedly been called, during the past fifty years, to the ill effects which may result from the use of articles colored with arsenical pigments. As a result, very stringent regulations exist in certain European countries restricting or preventing the manufacture, sale and importation of such articles.

For reasons not easy to understand, the importance of the subject does not appear to have been generally recognized in this country. The medical profession in Massachusetts has hitherto stood almost alone in its endeavors to impart to the community a proper knowledge of the subject and to secure restrictive legislation.

The State Board of Health early recognized the importance of affording the community some protection, and in their report presented to the legislature in January, 1872, published a carefully prepared paper by Dr. F. W. Draper, of Boston, "On the Evil Effects of the Use of Arsenic in certain Green Colors." In 1873, cases of poisoning by arsenic in a box factory at Lowell were investigated by Dr. E. G. Cutler, of Boston, whose paper was published in the seventh report of the Board, "with a special view to legislation on the subject." Again, in their tenth report, published in 1879, the Board expresses its opinion that "laws should be passed prohibiting the manufacture or sale of all articles improperly containing arsenic."

The investigation made by Dr. Draper was suggested by the extensive use as a pigment of the aceto-arsenite of copper (Schweinfürdt or Paris green). The arsenic acid process for the manufacture of magenta had been devised and patented twelve years before. But it was not very generally known till some years

later that arsenical colors are not limited to green, and that papers and other articles of every color are frequently arsenical owing to the use of arsenical anilines, or to the use of compounds of arsenic as mordants. In order to disseminate this information the State Board of Health, Lunacy and Charity published in the Health Supplement of their fifth report in 1884, a very complete article by Dr. E. S. Wood, entitled "Arsenic as a Domestic Poison."

In 1881, the Board of Health of the City of Boston, appreciating the importance of the subject, and the desirability of securing some legislation, secured an analysis of a large number of samples of papers and fabrics by Dr. W. B. Mills, whose results were published in the ninth report of the Board.

Four attempts have thus far been made to secure legislation in this State, in all of which the medical profession of Boston and vicinity has taken an active part. These attempts have all failed; yet they have been of incalculable service in securing to the community a great degree of protection from the dangers of arsenical poisoning. Probably less than five per cent. of the wall paper sold in Boston to-day are dangerously arsenical, against forty or fifty per cent. six or seven years ago. The number which contain as much as an accidental trace is to-day less than the number of highly arsenical ones then. This result has been brought about solely in consequence of the continued efforts of our Boards of Health, chemists and physicians. It is true that cases of wall-paper poisoning are still met with. But the majority of these are, we believe, caused by papers which were sold and put on the walls some years ago. These are beyond the reach of legislation.

We are of the opinion that the greatest danger at the present time is to be found in glazed papers, fabrics, and colors used for tinting walls. Any attempt to secure legislation directed to these is certain to provoke determined opposition owing to the extent of the industries involved. Yet the continued presentation of the subject is in every way desirable. Even if legislation is not secured, every attempt to secure it assists in imparting to the public a knowledge of the dangers which may result from the use of arsenical pigments. This knowledge will eventually prove as effectual in diminishing the danger as any legislative restrictions which can be obtained. When the public is so far educated as to demand non-arsenical colors, their use must cease. The results which have already been effected in the case of wall-papers, in the entire absence of any legislation, prove conclusively that the use of such pigments is wholly unnecessary. We believe, therefore, that no effort should be spared to secure the additional protection which will be afforded by the prohibition of the use of arsenical pigments on fabrics and other domestic articles.

The following is a translation of the inscription on the sign board of a "dispensary" in Milan: "Teeth extracted, corns cut, and tuberculosis cured after Professor Koch's method."

## THE ROLE OF THE LIVER IN THE PRODUCTION OF UREA.

UNTIL the time of Prevost and Dumas, it was believed that urea was formed in the kidney. These physiologists proved by their experiment of removing the kidneys in animals that urea is preformed in the blood or in the tissues, and from that day the kidney has been regarded rather as a filter than as a secreting organ destined to elaborate substances not previously existing in the blood.

Subsequently the doctrine was promulgated that urea is formed everywhere in the economy where nitrogenous waste is going on, its sources being metabolism of tissues and of unassimilated food-proteids. The muscles were believed to constitute no inconsiderable source; Wurtz's observation that lymph contains more urea than blood is suggestive of a direct relationship between urea and tissue-metamorphosis.

The facts which have given rise to the belief that the liver is the principal if not the only producer of urea may be briefly stated as follows:

It was discovered as early as 1846 that the urine of persons affected with chronic hepatitis contains little or no urea; twenty years later Meissner, basing himself on accurate analyses of the urine in acute yellow atrophy of the liver, laid down the law that destructive diseases of the liver entail diminution or suppression of urea. Bouchardat, in 1867, proclaimed that certain lesions of the liver are attended with augmentation of urea production, while others cause diminution. Brouardel and Marchison enriched medical literature by new observations showing "that the quantity of urea secreted and eliminated in twenty-four hours is dependent on two principal influences: the state of integrity or alteration of the hepatic cells, and the greater or less activity of the hepatic circulation.

In those cases which are characterized by augmentation of urea, the liver has not been found to be the seat of grave organic lesions, but only of simple functional disturbances, a hyperæmia, it may be, similar to what is observed in a certain number of cases of diabetes. In one case of spasmodic icterus, Bouchardat noted the enormous quantity of 133 grammes of urea in the twenty-four hours, and the excretion continued in this proportion for three or four days. Fourcroy and Vauquelin also announced about the same time (1846) that in icterus the urine may contain a very large proportion of urea. Foulhoux subsequently reported a case of simple hepatitis in which the figure of urea was double the ordinary.<sup>1</sup>

Facts of the second group—where there is diminution of urea—belong to cases of destructive lesions of the liver, where the whole extent of the hepatic parenchyma is affected. Under this head we find acute yellow atrophy of the liver, common cirrhosis, cancer of the liver which has invaded large portions of that gland, hydatid cysts, abscesses of considerable dimensions, granulo fatty degenerations of the liver, whether

<sup>1</sup> Chareot—*Maladies du Foie*, etc., 1882, p. 86.

following grave infectious fevers, or induced experimentally in animals.

Meissner's treatise contains the principal observations which have been made on animals confirmative of the pathological observations above mentioned. According to this authority, urea is not found in the muscles or in the lungs of mammals, but almost exclusively in the liver. In the liver of a dog which was bled to death, several centigrammes were obtained: the organ was carefully washed, and the vessels flushed out with warm water before being subjected to analysis. The results obtained by Meissner have been confirmed by Cyon, who concludes "that there is a real and rapid production of urea in the passage of the blood through the liver." Cyon appeals to facts similar to those adduced by Claude Bernard to prove that the liver produces sugar: the blood of the hepatic vein is found to contain more urea than the blood of the vena portæ.

Lecorché and Talamon<sup>2</sup> do not dispute the proposition that the liver produces urea, or that there is more urea in the hepatic than in the portal vein; they do dispute that the liver is the sole or the principal urea-forming organ. To the statement that in destructive diseases of the liver there is a diminution of urea, they oppose careful observations of their own, where, despite such destroying lesions (diffuse cancer, diffuse venous cirrhosis), the quantity of urea remained normal. This fall in the proportion of urea, of which Murchison and Brouardel make so much in its application to serious hepatic lesions, is equally characteristic of every disease of long duration, of every cachexia, cancerous, tuberculous or otherwise; it is, however, true, as a general rule, that in affections which alter the structure of the liver, the fall in urea-production is a little greater than in the chronic diseases of other organs. This is easily explained on the ground that the liver is an organ of great magnitude and importance; "it is quite natural that the quantity fabricated should fall considerably when a centre of formation so important is suppressed, but it will not do to push too far the consequences of this fact, and make ureopœiosis, that is, *urea making*, (from the Greek), a special function of the liver."<sup>3</sup> In fine, the diminution of urea, and the appearance of leucine and tyrosine and extractives in the urine are not accidents proper to acute yellow atrophy or other wasting diseases of the liver; "but simply an episode of the general perturbation imposed on the phenomena of dissimilation of the entire organism by the infectious disease."

Lecorché and Talamon next take up the facts adduced by Murchison and others, from which the conclusion is drawn that in states of hyperamnia, or excitation of the liver, the production of urea is exaggerated. This they admit to be true, but "polyuria, with augmentation of urea, is not peculiar to hepatic affections, being only a critical phenomenon, such as may be observed in any other acute disease; lastly, it

physiology seems to have demonstrated that urea is formed in the liver, clinical observation does not permit us to believe in a special function of that gland, but only in a phenomenon of dissimilation, such as takes place likewise in the intimate substance of all the tissues of the organism."

This, then, which is really the older doctrine, may, we think, be regarded as the latest authoritative teaching of science respecting the puzzling question of the sources of urea in the economy.

#### ANNUAL REPORT OF THE NEW YORK STATE BOARD OF CHARITIES.

In the twenty-fourth annual report of the State Board of Charities, just submitted to the Legislature, the claims for the further continuance of the supervisory work of the Board as regards public institutions for the insane, are discussed at some length. The Board of Charities thinks there are no reasons for the transfer to the State Lunacy Commission of the simple powers of supervision by the Board, inasmuch as they do not include any authority to order or direct changes in the institutions, or to modify the treatment of the insane, or to interfere with the Commission, but consist only of such as are necessary to give information to the Legislature. . . .

"The question is, shall the numerous and expanded institutions for the insane, extended over the vast territory of the State, the worst wards and inmost recesses of which are properly, and in great degree necessarily, closed to the public at large, be closed also against all official examination, except by the three salaried officials, who, however competent or personally eminent, are legally distinguished by being specially charged with the execution of the laws. The first answer is that these executive powers of the Commission, as construed by it, are similar, though superior, to those of the superintendents of the respective institutions; and, covering the vast territorial jurisdiction of the State, have already become so complicated and onerous as to induce the Commission to seek partial relief from their visitatorial and supervisory duties specified in the act of 1889, and to secure such relief by the amendatory act of 1890. The further and sufficient answer, which it is submitted should be conclusive, is that the State system for the care of the insane, which is necessarily withdrawn from public observation, should not by law be withdrawn also from official inspection."

The report places the number of insane in the custody of the institutions of the State on October 1, 1890, at 16,022, as against 15,538 on October 1, 1889. The poor-houses and almshouses of the State are stated to furnish shelter, in round numbers, for an average of 22,000 persons, 9,000 of whom are insane, and 13,000 otherwise disabled. A gradual and steady improvement in these institutions has undoubtedly taken place since the visits of the Board were inaugurated.

## BONE TRANSPLANTATION AT THE CHARITY HOSPITAL.

As a rule the medical discoveries heralded by the daily press are of questionable value. This, it may be added, is as true since the presentation of paratubercle as it was before. It is for this reason that little value was placed on the newspaper reports of the case of bone transplantation from a dog, announced several months ago in the *New York* daily papers: especially as the journals of that city have within a few years devoted some space to the exploiting of impossible surgical feats, and the sensational accounts of grave operations. But this opinion will not be held after reading the article by Dr. Phelps in the last number of the *New York Medical Record*, giving the details of his unusual case. Although transplantation of bone is no novelty, the method employed by Dr. Phelps is not only novel, but one which will not be frequently repeated, owing to the difficulty of commanding the necessary conditions; and although the result was not a surgical success, yet experimentally it is of great value.

It is natural that an attempt to temporarily unite a human being and a dog in a union as close as that of the Siamese twins should have excited the interest of a newspaper reporter, and also of the lay mind; but it is doubtful if either could appreciate the scientific importance of the question, or the value of the first attempt of the union of the circulation between the two branches of the vertebrates, hitherto entirely separated since the primeval division from the ancestral vertebrate whose nature and character even a Darwinian would be unable to define. The reason for the selection of a dog was, according to Dr. Phelps, the similarity of the elements of the blood. The experiment, which was certainly attempted in the cause of humanity, was carried out with a great deal of care and thoroughness. Any one who is familiar with laboratory work will admit that the problem which Dr. Phelps presented to himself was a most difficult one and one which gives credit even if only partially successful.

Of how great practical value this may be is at present a question. If, however, we take the broader view that no well-established fact is without value, it will be admitted that the case of Dr. Phelps is worthy of investigation. He has certainly made it easier for a second attempt in the same direction, should it be regarded as advisable; and considering the difficulty of his undertaking and the pains that were required to have carried out his attempt, the profession is certainly indebted to him not only for the work, but for the careful explanation of what was certainly a carefully prepared experiment.

## MEDICAL NOTES.

**SMALL POX IN TEXAS.**—Small-pox is still prevailing at different points in Texas and New Mexico, and is within twenty miles or less of the city of El Paso. The people are often unwilling to be vaccinated. In many of the towns no isolation is thought of.

**TYPHOID FEVER IN FLORENCE.**—Since the middle of December there has been an epidemic of typhoid fever in Florence, which is now fast diminishing. From December 16th to January 23d, 1,179 cases were reported, with a ratio of deaths ranging in different weeks from twelve to forty per cent.

**THE HARVARD MEDICAL SOCIETY OF NEW YORK CITY**, composed of graduates of the Harvard Medical School residing in New York, has recently been organized, with Dr. Rufus P. Lincoln as President, Dr. Paul F. Mundé as Vice-President, Dr. Dillon Brown as Secretary, and an Executive Committee consisting of the President, the Secretary, and Dr. Frederic R. Sturgis, Dr. William J. Morton, and Dr. Henry C. Coe. Meetings are to be held on the first Saturday of each month, except June, July, August, and September.

**THE PREVENTION OF NARCOTIC INEBRIETY.**—At a meeting of the American Association for the Cure of Inebriety, held February 18th at the Academy of Medicine, New York, Dr. J. B. Mattison, of Brooklyn, offered the following preamble and resolutions:

*Whereas*, a leading cause of morphinism, chloralism and cocaineism is the facility with which morphine, chloral and cocaine can be procured from pharmacists; and,

*Whereas*, the refilling of prescriptions containing these drugs is a potent factor in the rise and growth of these diseases.

*Therefore, be it resolved*, as the sense of this Association, that no retail druggist should sell morphine, chloral or cocaine, except on a physician's prescription; that no prescription containing morphine, chloral or cocaine should be refilled, except on the written order of a physician.

These were unanimously adopted, and a committee consisting of Drs. Mattison, Crothers and Wright was appointed to secure legislation along the line of the resolutions.

**A LEPROSY COMMISSION TO INDIA** has been dispatched from England, which, after an investigation of one year, is expected to report concerning the desirability or otherwise of encouraging the voluntary partial withdrawal of lepers from among the non-leperous population; of enforcing the complete isolation of all lepers; and of enforcing the isolation of certain lepers. It will also report on the best methods of accomplishing whatever may be decided upon.

**AN AFRICAN SANATORIUM.**—The German Emperor has given a sum of 20,000 marks towards the erection of a sanatorium in some "elevated healthy region of German East Africa." A German hospital has been built at Dar-es-Salaam.

**INFELCENZA AND CHILDREN'S GROWTH.**—A systematic course of observations of the growth in weight of the children in the Deaf-mute Institution at Copenhagen has been kept up for seven years. Among the most striking results is the fact that the principal increase takes place in the autumn months. In the year 1889, influenza appeared in Copenhagen toward the end of November. Six of the professors of the institution were attacked, while no pronounced cases were de-

veloped among the pupils. At the same time, for four weeks after the 23d of November, the weight of the boys increased only two-fifths as rapidly as it had done in the corresponding weeks of the previous years, while the girls gained nothing.

**INJECTION OF DOG SERUM AS A REMEDY FOR TUBERCULOSIS.**—In a series of communications made in the course of the last two years to the Société de Biologie, MM. Héricourt and Richet have given the results obtained by the injection of the blood of an animal refractory to tuberculosis, such as the dog, into the economy of one susceptible to the disease. They have demonstrated experimentally that such a proceeding exerts a retarding influence on the evolution of tuberculosis artificially communicated, without, however, stopping it altogether. With a view of intensifying these partially protective properties of canine blood, they inoculated the dog with a large dose of very active tuberculous matter, and one month later (the animal having lost flesh, and exhibiting manifest signs of ill health) injected into the peritoneal cavity of rabbits 70 cc. of the dog's blood. Encouraged by their results, they have extended the application of their method to tuberculous human beings, employing the serum only. M. Richet reports that four phthisical men have, since the early part of December, 1890, been subjected to this treatment. The results obtained seem to warrant the assumption that the introduction of the serum of dog's blood into the human economy counteracts, to some extent at least, the influence of Koch's bacillus.

**ADDITIONS TO THE BRITISH PHARMACOPEIA.**—Amongst the new drugs introduced are: Sulphonal, phenacetin, paraldehyde, picrotoxin, oil of cade, hydrobromate of homatropine, eucalyptus gum, acetanilide, gluside, and phenazone, the last three being official names for antifebrin, saccharin and antipyrine respectively. "Lanoline" appears in the additions as hydrous wool fat (*adeps lanae hydrosus*). Wool fat is described as "the purified cholestrin-fat of sheep's wool," and the hydrous variety is to be made from this by the addition of thirty per cent. of water. Among the new preparations are: a tincture and ointment of hamamelis, syrup of ferrous chloride, and *pilula ferri*, the latter representing Bland's pill, and each five-grain pill to contain about one grain of carbonate of iron; menthol plaster; castor oil mixture, in which the oil is emulsified with the aid of solution of potash and syrup, the mixture being flavored with oils of lemon and cloves, whilst orange-flower water is used as a vehicle (two ounces of the mixture contains six drachms of castor oil); sulphur lozenges, each containing five grains of precipitated sulphur, and one grain of acid tartrate of potassium; and ointment of hemlock, made by adding hydrous wool fat and a little boric acid to evaporated hemlock juice.

## NEW ENGLAND.

**LEGISLATIVE HEARINGS.**—Those in favor of the petition that unvaccinated children may be allowed to

attend schools appeared before the Committee on Public Health. There was a hearing before the same committee in regard to the expediency of enacting a law which will prevent the manufacture or sale of articles of household or personal use containing arsenic, where such articles may be dangerous to the health of the community. Edward S. Hale, Esq., appeared for the petitioners. John D. Long, Esq., appeared for the dealers in paper-hangings, as remonstrants. The petitioners in favor of some regulation in the use of arsenic were heard, and the hearing was continued to March 11th. Petitions were presented from five hundred people.

**CHARITY CLUB HOSPITAL FAIR.**—A fair is being held in Boston by some interested and energetic ladies in behalf of the Charity Club Hospital.

## NEW YORK.

**TWO CASES OF SMALL-POX,** the first, it is said, that have been reported in the city for about two years, were discovered by the health authorities on February 20th. Both the patients, who were Armenian peddlers, were removed to the hospital, and every precaution was at once taken to prevent any spread of the disease. A large number of the residents in the vicinity of the men's lodgings were vaccinated by the sanitary corps.

**GIFT TO THE WOMAN'S HOSPITAL.**—Mr. Morris K. Jesup has made a generous gift of \$100,000 to the Woman's Hospital. It is to be known as the Abby Sherwood Jesup fund, in memory of his mother, and the income from it is to be used in giving the benefits of the hospital to women who are in whole or in part able to pay their own expenses.

**FIRE IN ST. MARY'S HOSPITAL.**—St. Mary's Hospital, at Rochester, was destroyed by fire, on the night of February 15th. There were in the institution at the time 250 patients, 19 Sisters of Charity, and a considerable number of employees, but they all escaped in safety. One fireman, however, was unfortunately fatally injured by a falling cornice. The loss of property amounted to some \$65,000, and the insurance on it was only about \$20,000. The entire building had just been thoroughly repaired and newly fitted up at an expense of \$50,000. The hospital was a three-story stone structure, with two long wings and a tower at the end of each of the latter. It was founded a number of years ago by Mother Hieronyma, who has just completed her fiftieth year of service as a nun in the Roman Catholic Church; an event which was to have been celebrated with appropriate ceremonies on the day after that on which the fire occurred.

**DR. GAIUS LEONARD HALSEY,** a well-known physician of Central New York, died at Unadilla on February 17th. During the past year he published an account of a trip which he made to California during the gold fever of 1849, and also some interesting reminiscences of a physician's life in a country village fifty years ago.

## Miscellany.

### EFFECTS OF OREXIN ON ASSIMILATION.<sup>1</sup>

THE effects of hydrochlorate of orexin on the assimilation of nitrogen and fat and on the nitrogenous metabolism in healthy as well as in diseased subjects has recently been studied by Dr. E. T. Kotliar, chief of Professor Manassein's therapeutic clinic in St. Petersburg, the pathological cases comprising three of chronic gastric catarrh and one of carcinoma of the stomach. The results obtained are thus summarized. Orexin given in quantities of from five to twelve grains daily for four or five days increases the assimilation of nitrogen both in healthy and in diseased subjects. It increases the assimilation of fat in diseased subjects. The nitrogenous assimilation is lessened to a marked degree in healthy persons, but much less so and less constantly in diseased subjects. In both classes of individuals the appetite is improved, the sensation of hunger not, however, being always increased.

### DISINFECTION OF TUBERCULOUS SPUTUM.

DR. MARTIN KIRCHNER<sup>2</sup> points out that tubercle bacilli are more resistant than some other micro-organisms to the action of some antiseptic fluids, but are very easily destroyed by others. Four per cent. carbolic acid with the addition of two per cent. of hydrochloric acid; or ten per cent. creolin, will suffice to render tubercle bacilli innocuous in a very short time. Caustic soda and potash on the other hand, and five per cent. permanganate of potash have no effect, nor is a solution of 1 in 1,000 of corrosive sublimate sufficient, owing to the highly albuminous character of the sputum in which the bacilli are contained. It has now been proved that tuberculous sputum may retain its infective properties for ten months even after decomposition or drying up. A temperature of 70° C., has been shown to be insufficient to render tuberculous sputum innocuous, and the author believes that absolute disinfection is only to be obtained by means of steam. This plan was advocated by Grancher and De Genes in 1888, but the apparatus devised for the purpose was cumbersome and costly.

Now that there is a general disposition to treat tuberculous cases by collecting them together, it should be an absolute law that all the sputum proceeding from such cases should be rendered harmless before it is disposed of in the common drains. With this object, Dr. Kirchner has caused a form of disinfecting kettle to be constructed, consisting of a round metal box about ten inches high and sixteen inches in diameter, its floor forming a shallow tank to hold the water to be vaporized, the whole being covered with a lid perforated at one point for the passage of a thermometer. In this box are placed two or more trays perforated to permit of the free circulation of steam, and so arranged as to carry five pitting cups of the special pattern which he uses. These cups are placed for half an hour within the apparatus, heat being maintained so that the temperature of the steam never falls below 100° C. Small cups made of glass with wide lips and ends, conical, should be used in preference to the spittoon, but not be placed within reach of the patient's

hand, and be clearly labelled. These cups must be placed in the disinfecting box for half an hour before they are emptied, and their contents may then with safety be treated by simple washing.

### MACEWEN ON THE CURE OF ANEURISM.

IN an address delivered before the Midland Medical Society, Dr. Macewen<sup>1</sup> remarks upon the methods of curing aneurism by acting directly upon the blood stream to bring about coagulation. When the current of blood is unobstructed, white thrombi are prone to form in the interior of a vessel at a spot where irritation has been induced, and from which the endothelium has been removed. When this process has been initiated, it tends to grow by superimposed accretions, so that a partial thrombosis may proceed until complete occlusion occurs. In large aneurismal sacs it is, as a rule, many months before occlusion by this process takes place.

A thrombus formed by acting on the contents of an aneurismal sac is different from one induced by acting on its walls. The introduction of foreign bodies into the sac of an aneurism in which the blood is freely circulating, with the object of forming red thrombi, is not the most certain way of producing permanent occlusion of the vessel. White thrombi are more suitable for permanent aneurismal occlusion under such circumstances. A white thrombus may be secured in an aneurismal sac by irritating the wall of the aneurism in such a way as to induce infiltration of the parietes with leucocytes and a segregation of them from the blood stream at the point of irritation. The irritation ought to be just sufficient to set up reparative exudation, and should not exceed it; if the irritation be pushed to such an extent as to induce softening of the vessel wall, not only would the object be frustrated, but the pressure of blood from within might cause the aneurism to burst. It is better to provide many foci of thrombi, either by producing a uniform irritation over the whole inner surface, or by stimulating as many points as possible.

The instrument employed is a pin of sufficient length to completely transfix the aneurism and to permit of manipulation within it. Its calibre ought to be as fine as possible, the strength being only sufficient to penetrate the coat of the aneurism and the intervening tissues. It is cylindrical, tapers to a point like an ordinary sewing needle, and has on the opposite end a somewhat rounded head. As the coats of aneurismal sacs vary in thickness, it is necessary for the pins to vary in calibre. They should also be finely polished.

The operation is preceded by careful cleansing and asepsis of the skin over the aneurism. The aseptic pin is then made to penetrate the sac, and pass through its cavity until it comes in contact with the opposite side, and no farther. Then irritation may be affected, either by moving the pin over the surface of the inner wall, or by allowing the impulse of the blood-current playing on the very thin pin to produce the same result. If the wall, penetrated by the pin, on introduction be dense, the former method will be preferable, as the force of the blood-current will produce so feeble an action on the thin pin as to be insufficient to move

<sup>1</sup> An Address on Aneurism, by William Macewen, M.D., of Glasgow. British Medical Journal, November 15, 1900, and Annals of Surgery, January, 1901.

<sup>2</sup> The Lancet, January 15, 1891.  
 Communicated by the Editor, No. 1, 1891.

it to and fro, while it is firmly grasped by a dense wall. After acting thus for ten minutes at one part, the point of the pin, without being removed from the sac, ought to be shifted to another spot, and so on, until the greater portion of the internal surface opposite to the point of entrance has been acted upon. A single insertion of the pin through the aneurismal sac into its interior may be sufficient to enable the point of the instrument to come into contact with the greater part of its internal surface, but in some cases puncture from various sides of the external wall may be necessary. In the case of a very large aneurism, several pins may be introduced from various points.

In some cases Dr. Macewen has repeated the irritation many times at intervals of weeks. Four cases are detailed, in two of which the clinical results were verified by a subsequent pathological examination. Of these four cases, one involved the innominate, one the left subclavian, one the abdominal aorta, and one the upper part of the femoral implicating the external iliac. Two of these were absolutely cured by the induction of white thrombi within the sac. One was so greatly relieved that he was able to resume his work as a locomotive engine driver. One died after two months' treatment from asphyxia when the aneurism was two-thirds healed, and when complete consolidation was within a few weeks of consummation.

In connection with the subject Dr. Macewen remarks that any method which would induce the occlusion of the sac by the formation of white thrombi and its consequent organization into living tissues, might be used, provided it evinced any superiority to this one. Such a one in particular would be a method which, while equally successful and easily applied, would do away with the necessity of opening the sac.

### PRESCRIPTIONS.

**ERGOTIN IN CHRONIC GONORRHOEA.** — Roicki,<sup>1</sup> a Russian, uses the following solution of ergotin:

R Ergotin . . . . . grs. v.  
Aque destil. . . . . 3 i M.

Use as an injection several times daily. Ergotin is given by the mouth at the same time.

**CREOLIN IN INFANTILE DIARRHOEA.** — Schwing<sup>2</sup> recommends the following mixture for infants who are suffering from diarrhoea:

R Creolin . . . . . grs. i to ii j.  
Aque cinnamon. . . . . 3 i ss.  
Syrup . . . . . 3 ss.

Mix, and administer a coffee-spoonful every two or three hours.

### Correspondence.

#### PUBLICATION OF THE RESULTS BY KOCH'S METHOD.

Boston, February 22, 1891.

MR. EDITOR: — It seems to me high time that notices similar to the following from the Boston *Transcript* of February 21st should meet with criticism at the hands of men able to give an opinion as to the results of the treatment of patients by Koch's material.

"Of the twenty-four patients who were first accepted at the Massachusetts General Hospital for treatment with Professor Koch's remedy for tuberculosis, about half have been discharged. This is not to indicate that the cure is completed in every case, but the improvement is so marked that they have been sent to their homes to report after a time that varies according to the condition of each case. If the patient continues to show the improvement that is now to be noted, the discharge will be permanent. A marked improvement is shown in the case of all the patients who have been under treatment.

"Nearly all the places left vacant have been filled, and only two beds remain vacant; but these will be filled at once from the long list of applicants now on file. A second consignment of lymph has been received from Germany, which is enough to continue the treatment upon those now in the hospital for some time; and it is expected that more will be sent over before the present supply is exhausted.

"Applications are still received at the hospital from those who desire to begin the treatment, but these are not frequent. For the first four weeks they kept pouring in, and it required considerable additional work to examine all that applied; but it is now done without difficulty."

While physicians are carefully experimenting with the material, and as yet have expressed no opinion as to the ultimate result of the treatment, the public are led to believe that we have under our control a material which is almost a sure cure for tuberculosis.

It seems to me but just to those suffering from tuberculosis that they should be informed that, as yet, the treatment by Koch's method is only a great clinical experiment. The public have not access to scientific journals where they can read that, as yet, even the most enthusiastic adherents of this method of treatment have not demonstrated or claimed a single case of cure of any tuberculous lesion.

Respectfully yours,  
HENRY JACKSON, M.D.

#### RECORD OF MORTALITY FOR THE WEEK ENDING SATURDAY, FEBRUARY 13, 1891.

Cities.	Estimated population for Feb.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 14, 1891, TO FEBRUARY 20, 1891.

By direction of the Secretary of War, Captain LOUIS M. MAY'S, assistant surgeon, is relieved from further duty at Fort Stanton, New Mexico, and will report in person to the commanding officer, Whipple Barracks, Arizona, for duty at that station, relieving Captain RICHARD W. JOHNSON, assistant surgeon. Captain JOHNSON, on being relieved by Captain MAUS, assistant surgeon, will report in person to the commanding officer, San Carlos, Arizona Territory, for duty at that station. S. O. 25, Par. 7, A. G. O., Washington, D. C., February 12, 1891.

By direction of the Secretary of War, Lieutenant-Colonel CHARLES C. BYRNE, surgeon, is relieved from duty at Fort Sam Houston, Tex., and will report in person to the commanding general, Department of the Columbia, for duty as medical director of that Department, relieving Colonel FRANKLIN J. P. BERRY, surgeon. Colonel BERRY, on being relieved by Lieutenant-Colonel BYRNE, will proceed by the way of San Francisco, Cal., to St. Louis, Mo., and report in person to the commanding general, Department of the Missouri, for duty as medical director of that Department, relieving Colonel CHARLES PAGE, assistant surgeon-general. Colonel PAGE, on being relieved by Colonel BERRY, will report in person to the commanding general, Department of the Atlantic, for duty as medical director of that Department. S. O. 25, Par. 6, A. G. O., Washington, D. C., February 13, 1891.

#### SOCIETY NOTICES.

REPORTS SOCIETY FOR MEDICAL OBSERVATION. A regular meeting of the Society will be held, at 19 Bayston Place, on Monday evening, March 24, at eight o'clock.

Readers: Dr. A. H. Nichols, "Simulated Primary Dementia. A Medical-Legal Case"; Dr. W. F. Temple, "A Report of Some Cases of Syphilis"; Dr. E. H. Fitz, "Intestinal Perforation in Typhoid Fever."

Report of Treasurer. Report of Committee on Admissions. T. F. SHERMAN, M.D., Secretary.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a meeting of this Section, at 19 Bayston Place, on Wednesday evening, March 4th, at eight o'clock. Dr. G. W. Allen will read a paper on the "Treatment of Acute Urethritis." Dr. D. W. Cheever will report a case of Compound Dislocation of the Hip-Joint. Dr. S. N. Nelson will show a patient in whose body four large pistol-balls were lodged, only one of them having been removed. Dr. S. J. Mixer will read a short paper, the subject of which will be announced on the card.

GEORGE H. MONKS, M.D., Secretary.

AMERICAN MEDICAL ASSOCIATION. — The forty-second annual session will be held in Washington, D. C., on Tuesday, Wednesday, Thursday and Friday, May 5th, 6th, 7th and 8th, commencing on Tuesday at 11 A. M.

HARVARD MEDICAL SOCIETY OF NEW YORK. — A regular meeting will be held at the residence of Dr. R. F. Lincoln, 22 West 31st Street, on Saturday, March 7, 1891, at 8.30 P. M. Paper by Dr. H. C. Coe, "Diagnosis by Exclusion." If unable to attend, please notify Dr. Lincoln.

DR. DILLON BROWN, Secretary, 102 East 57th Street.

DR. R. P. LINCOLN, President.

SIXTH ANNUAL MEETING OF THE ASSOCIATION OF AMERICAN PHYSICIANS. — The following preliminary programme has been announced:—

1. The President's Address, William Pepper, Philadelphia. 2. Discussion on the Relations between Arterial Disease and Visceral Changes. Referee, George L. Peabody, New York; Co-Referees, James K. Thacher, New Haven. William T. Councilman, Baltimore. 3. Discussion on the Remote Results of the Removal of the Ovaries and Tubes. Referee, William T. Lusk, New York; Co-Referee, Wharton Stalker, Philadelphia. 4. Discussion on the Treatment of Visceral Tuberculosis by Koch's Method. Reports by Francis P. Kinnicut, New York; Harold Ernst, Boston; William Oster, Baltimore; Commission of University of Pennsylvania, reported by Drs. Musser and Griffith, Philadelphia. 5. Experimental Studies on the Causes of the Localization of Pulmonary Phthisis, and certain other Infectious Diseases in the Lungs. J. West Roosevelt, New York. 6. The Relation of Drinking-waters to Disease. Henry F. Walcott, Cambridge. 7. Intestinal Perforation in Typhoid Fever. R. H. Fitz, Boston. 8. On Changes in the Red Blood Corpuscles in the Pernicious Anemia of Texas Cattle Fever. (By invitation.) Theobald Smith, Washington. 9. On the Diseases of the Kidney, popularly called "Bright's Disease." Francis Delfield, New York. 10. The Use of Albuminous Food in Diseases of the Kidney. William H. Draper, New York. 11. Bradycardia in Acute Articular Rheumatism. I. E. Atkinson, Baltimore. 12. The Treatment of Epileptiform Neuralgia. James Stewart, Montreal. 13. The Condition and Prospects of the Library of the Surgeon General's Office, and its Index Catalogue. John S. Billings, Washington. 14-16. Papers by Norman Bridge, Chicago; JOHN GUTKES, Philadelphia; William F. Whitney, Boston. Titles to be announced subsequently.

The meeting of the Association will be held at Washington, D. C., September 23d, 24th, 25th, in connection with the Second Congress of American Physicians and Surgeons.

#### DEATHS.

S. L. Chase, M.D., of Colchester, Conn., died February 15th.

Lealand J. Graves, M.D., died at Claremont, N. H., February 12d, aged seventy-nine years.

James H. Eldridge, M.D., died at East Greenwich, R. I., on February 20th, aged seventy-five.

Henry W. Stevens, M.D., Assistant Pathologist at the New York Hospital, died February 23d, aged thirty-three years.

Henry C. King, M.D., died at Phenix, R. I., on February 21st, aged sixty-three. He lived formerly at Aponeau and Providence.

Marius Duvall, M.D., Medical Director of the United States Navy, retired, with the relative rank of Commodore, died in Baltimore, February 21st, aged seventy-three.

J. A. Mend, M.D., died recently in New Orleans, aged forty-nine. He graduated from the Harvard Medical School in 1863, and since then has practiced in the South.

Theobald Obersteiner, M.D., who had been the body-physician of Maximilian, Emperor of Mexico, died in Vienna, January 25th, aged seventy-one. He was the father of the present Professor Obersteiner of Vienna.

## Original Articles.

BOSTON HOSPITALS.<sup>1</sup>

BY CLARENCE J. BLAKE, M.D., BOSTON.

THE writer of the Boylston prize essay for 1860,<sup>2</sup> in quoting the saying of Rousseau, "I know that the truth is in things and not in the mind which judges them,"<sup>3</sup> as having been used as evidence for the value of statistics, remarks further that the sentence contains also the germ of their fallacy, since statistics tend, when carried too far, to separate reason from observation; to ignore the subjective and to study only the objective phenomena of disease, and would lead the medical observer to overlook the fact that it is by his mind that he judges, and that the rectitude of his decision depends on his own mental acuteness.

The following statistical paper is presented, therefore, merely as a contribution of material which may possibly be made variously useful by others, while its collection has served the personal purpose of the writer in answering several questions naturally suggesting themselves in the consideration of so interesting a subject as the double purpose of the care of the physically disabled and the training of their self-constituted friends and helpers, a combined use of hospital foundations which has its sanction in precedent and age, ever since the establishment of a hospital and clinical school, the first of its kind, at Odessa in the fourth century, as well as in the broader intelligence and more widely diffused charitable spirit of to-day.

The extent and distribution of hospital service is necessarily limited by centres of population and physical demands; beyond these it may be justly said there is, in such a centre as Boston for instance, no limit to the provision which will be made by the well and well-to-do for the sick and needy, if only the need is justly demonstrable on a common-sense basis.

As obtained from the Bureau of Statistics,<sup>4</sup> the city of Boston has at present an estimated population of 446,547, and there is in addition, within a twelve-mile radius, a suburban population of over 400,000, distributed as follows:

## POPULATION, BOSTON AND VICINITY.

Boston . . . . .	446,547	Lynnfield . . . . .	785
Cambridge . . . . .	69,837	Medford . . . . .	11,052
Chelsea . . . . .	27,850	Melrose . . . . .	8,500
Lynn . . . . .	55,094	Milton . . . . .	4,278
Malden . . . . .	22,984	Nahant . . . . .	899
Newton . . . . .	24,357	Needham . . . . .	3,033
Somerville . . . . .	40,117	Quincy . . . . .	16,711
Waltham . . . . .	18,522	Reading . . . . .	4,080
Arlington . . . . .	5,625	Revere . . . . .	5,652
Belmont . . . . .	2,076	Saugus . . . . .	3,633
Braintree . . . . .	4,845	Stonham . . . . .	6,158
Brookline . . . . .	12,676	Swampscott* . . . . .	3,185

Lexington . . . . .	3,666	Woburn . . . . .	13,491

\* Hull, Swampscott and Wellesley are beyond the twelve-mile radius as measured on the railroads.

<sup>1</sup> Delivered before the Thursday Evening Club, February, 1891.

<sup>2</sup> Dr. J. W. Cheever: The Value and the Fallacy of Statistics in the Observation of Disease.

<sup>3</sup> "Je sais que la vérité est dans les choses, et non dans mon esprit qui les juge; et que moins je mets du mien dans les jugements, plus j'en porte, plus je suis sûr d'approcher de la vérité."

<sup>4</sup> In using these figures it should be stated that they are subject to further revision, as the result of the official count now in progress.

Of the towns above enumerated five, namely, Cambridge, Lynn, Newton, Waltham and Quincy, with a total population of over 185,000, have already established hospitals of their own, with an aggregate of 135 beds, and with out-patient services or provision for the reception of such charity patients as come merely for advice or for such treatment as may be required without admission to the hospital.

Setting aside the recognized tendency of movement toward a large centre of population, which must always operate in a degree against the utilization of the suburban hospitals, a tendency favored in the case of Boston by its ample railroad connections with the suburbs, it is proper to estimate the population of Boston and vicinity within available reach of its hospital accommodations as at least 650,000.

This estimate leaves out of consideration the patients who may come from beyond the twelve-mile-radius towns, and who do very frequently come to the larger hospitals and clinics, as the records of those institutions show: for example, of patients admitted to the City Hospital in 1889, 1,415 were natives of Boston, and 487 of other towns in Massachusetts, about 25% of the whole number from the State coming from outside of Boston; there were admitted to the Massachusetts General Hospital in the same year 1,095 natives of Boston, 2,010 from other towns in Massachusetts, or a little over 64% from places in the State other than Boston; while the out-patient departments of the Massachusetts Charitable Eye and Ear Infirmary in the same year received 7,741 patients from Boston, and 6,030 from other parts of Massachusetts, a proportion of over 43%; to this must be added the patients who come from still greater distances, and who make, at a moderate estimate, from five to ten per cent. of the *clientèle* of our hospital clinics.<sup>5</sup>

To provide for this demand we have in Boston certainly twelve hospitals, and at least six distinct out-patient institutions or dispensaries, the largest of which maintains an extensive house visit or district service in addition to the work at its central office.

Some idea of the accommodation provided for that class of patients requiring removal from home to the continued care afforded by a hospital, and which is absolutely necessary to recovery in many cases, and can in no other way be so adequately furnished, is given by a glance at the number of beds in the general hospitals:

Massachusetts General Hospital, <sup>6</sup> Blossom St. . . . .	273
Boston City Hospital, <sup>7</sup> Harrison Ave. . . . .	512
Carney Hospital, Old Harbor St., So. Boston . . . . .	225

These, with exception of the Homœopathic Hospital, East Concord Street, 73 beds, which will have next year with its two new wings, 220 beds, comprise the "general" hospitals receiving all classes of patients, and affording a total of over 1,000 beds, while the house accommodation provided by the following special hospitals largely supplements the work of the general hospitals, which latter also include special

and nearly completed at Washington; the revision will not materially affect the results, but will possibly change them slightly.

<sup>5</sup> Of patients coming from considerable distances to enter hospitals many pay something toward their support while inmates, and are not, therefore, entirely a charge upon the institution; the amount paid usually falls short of the actual cost of maintenance.

<sup>6</sup> Medical beds 82; surgical 109; private rooms for both medical and surgical 36; abdominal ward (surgical) 15; equals 243, to which should be added the beds in the Convalescent Home, Waverly 30.

<sup>7</sup> Medical beds 109; surgical 191; private rooms 24; contagious wards 56; equals 480; Convalescent Home 32.

departments within themselves, showing to any one who has followed the development and growth of these institutions during the last decade an evidence of that specialization found in all occupations as a mark of the rapid growth of a community.

Children's Hospital, Huntington Avenue, to which it has been necessary within two years to add a new wing, receives children of all classes under twelve years of age, and has, in addition to its hospital building in town, a convalescent home, with eighteen beds, in Wellesley.	73 beds
Boston Lying-In Hospital, McLean Street, now in process of rebuilding and enlargement, to meet the pressing demands upon its services, when completed will have over . . . . .	70 beds
Free Hospital for Women, East Springfield Street, has at present twenty beds, but will soon remove to a larger building, on the corner of Park and Marion Streets, Brookline, within easy reach of the city proper, by means of the electric road, affording . . . . .	50 beds
the present building remaining in the hands of the Hospital for use as a dispensary or out-patient clinic with a few beds for emergency cases.	
Women's Charity Club Hospital, Chester Park, . . . . .	12 beds
New England Hospital for Women and Children, Dimock Street, Roxbury, maintaining also a dispensary for women and children in Fayette Street, city proper . . . . .	68 beds
St. Elizabeth's Hospital, having with its branch hospital at Fort Avenue, Roxbury, a total of . . . . .	68 beds
West End Nursery and Hospital for Infants, Blossom Street, . . . . .	18 beds
House of the Good Samaritan, McLean Street, . . . . .	28 beds
Massachusetts Charitable Eye and Ear Infirmary, Charles Street, accommodates at present seventy house patients, but the demand upon the Institution has necessitated for aural patients additional wards, which will be completed during the present year, and will bring the house service up to . . . . .	90 beds

The hospital accommodation for the urban and suburban population of 650,000 may, therefore, be stated in the aggregate as a little less than 1,500 beds, though this enumeration does not include the private hospitals nor the beds maintained as purely secondary to out-patient clinics which may be the nuclei of future hospital establishments, as in the case of the Vincent Memorial Hospital now building as an addition to the Chambers Street Evening Dispensary for Women.

For purposes of comparison it is interesting as well as important, to note that New York city, with an estimated population of 1,470,306, has an aggregate of 5,380 hospital beds; Philadelphia, with a population of 1,020,318, has 3,697 hospital beds;\* and Baltimore, with 392,272 population, has 1,059 hospital beds, or, to put the estimate in another form, the proportion of hospital bed accommodation to the population is in

New York . . . . .	1 to 273
Philadelphia . . . . .	1 to 276
Baltimore . . . . .	1 to 370
Boston proper . . . . .	1 to 301

Or, if we include the immediate suburbs, which are virtually a part of Boston in their relation to it as previously mentioned, but 1 to 438.

Edinburgh, Scotland, is situated in regard to its suburbs and the surrounding country in respect to hospital work very much as is Boston, and it sustains, moreover, one of the most successful medical schools in the world; an estimate of a comparative character is therefore of interest. The present estimated population of Edinburgh and Leith is about 500,000, and there are in the city the following hospitals for the care of the sick to which the poor are admitted:

\* This estimate includes the Blockley Almshouse and Philadelphia Hospital with 1,400 beds.

Royal Infirmary, now 700, soon to be increased to 1,000	
Convalescent Home . . . . .	60
Royal Maternity . . . . .	30
Royal Hospital for Sick Children . . . . .	80
Chalmers Hospital . . . . .	40
Longmore Hospital . . . . .	70
Leith Hospital . . . . .	70
City Hospital (Fever) . . . . .	200
	1,560

Or a proportion of beds 1 to 290 of the population, exclusive of small special hospitals, of from five to ten beds each. This estimate is restricted to hospitals proper in the American use of the term, and does not, of course, include such institutions as Donaldson's, Stewart's and Heriot's Hospitals, which are schools for boys and girls, and omits, as was also done in the estimates for New York, Philadelphia, Baltimore and Boston, the large asylums and homes for incurables.

The discrepancy between need and supply in Boston would indicate the necessity either for a considerable increase of the suburban hospitals now affording but one bed to about eleven hundred of their local population, a considerable increase of the present urban hospitals, or in the near future the establishment of a new hospital in the direction of city growth.

That the enlargement of the present suburban hospitals and the building of others will do much to relieve the city hospital beds is not to be expected, in view of the always dominant centralizing tendency already mentioned, and in this suggestion lies the opportunity of the man of wealth who would make for himself a monument perpetuated in the need and the gratitude of the people.

What is true of the relationship between city and suburban hospitals as to house patients, is true in a still greater degree of the out-patient service; the ambulant patient can, as a rule, be treated where he wills, and where easy transport takes him, and in accordance with the law just mentioned, gravitates toward the largest centre; of this fact, and of the further fact that the demand for out-patient relief in the city is far in excess of the demand for hospital relief proper, the maintenance of a large number of institutions for the treatment of this class of patients alone, stands in evidence.

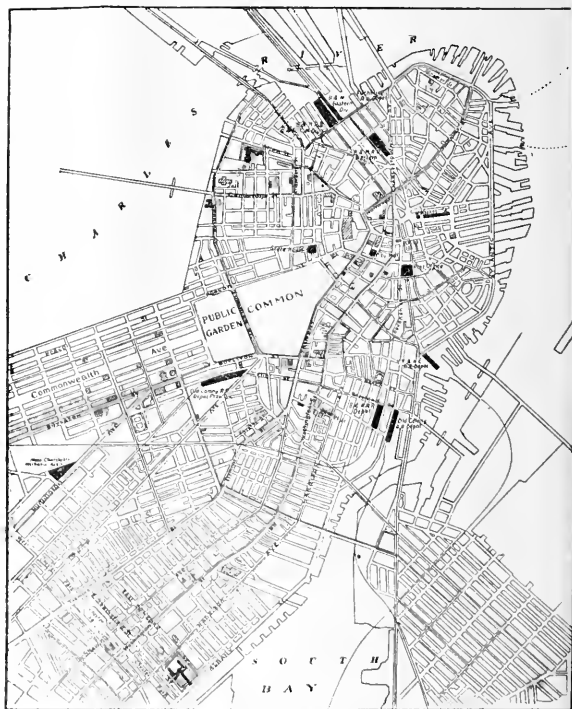

Of these charities the largest is the Boston Dispensary, situated on the corner of Bennett and Ash Streets, a building with a central waiting-room, and surrounding accommodations for twelve distinct out-patient departments, in which there were received and treated in one year over 21,000 new patients, in addition to the 12,167 new patients visited in their homes, under the excellent system of district service maintained by this institution, making a total of nearly 34,000 new patients in one year.

The dispensary in Fayette Street (New England Hospital for Women and Children) treated during the past year 4,130 new patients, and the Eye and Ear Infirmary nearly 15,000, while the out-patient departments of the larger hospitals show in gross the following figures as representing the new patients in one year:

West End Nursery . . . . .	1,000
Children's Hospital . . . . .	1,275
St. Elizabeth's Hospital . . . . .	3,576
Carney Hospital . . . . .	4,082
City Hospital, 1889 . . . . .	13,605
Massachusetts General Hospital, 1889 . . . . .	22,339

Plan of Boston Showing Position of Hospitals.

- |                                                      |                                               |
|------------------------------------------------------|-----------------------------------------------|
| 1 City Hospital.                                     | 10 Medical Library Building.                  |
| 2 Massachusetts General Hospital.                    | 11 Bonnet Street Branch of Lying-In Hospital. |
| 3 Old Medical School. Clinics.                       | 12 Boston Dispensary.                         |
| 4 Eye and Ear Infirmary.                             | 13 Free Hospital for Women.                   |
| 5 West End Day Nursery.                              | 14 Charity Club Hospital.                     |
| 6 Lying-In Hospital.                                 | 15 St. Elizabeth Hospital.                    |
| 7 Evening Dispensary for Women and Vincent Memorial. | 16 Fayette Street Dispensary.                 |
| 8 Stamford Street Dispensary.                        | 17 Children's Hospital.                       |
| 9 Harvard Medical School.                            | 18 Carney Hospital.                           |
|                                                      | 19 Charter Street Dispensary.                 |

an aggregate of over one hundred thousand patients treated in one year outside of hospital wards, without including in the enumeration the Free Dispensary for Women and Children in Staniford Street, the North-End Dispensary in Charter Street, the Jamaica Plain, Charlestown and Roxbury Dispensaries, the evening Dispensary for Women in Chambers Street, the clinic of the Free Hospital for Women, and the Homœopathic Dispensaries in Burroughs Place, Chardon Street, and East Concord Street.

A glance at the accompanying map,<sup>9</sup> which gives the hospitals and dispensaries and the street railway lines most directly connecting them, in red, shows that the hospital supply of the city is so distributed at present as to make three distinct centres with intermediate and outlying institutions. One group includes the Massachusetts General Hospital, the old Medical School, now used for clinics, the Lying-in Hospital, House of the Good Samaritan, West-End Nursery, Vincent Memorial and Staniford Street Clinics and the Eye and Ear Infirmary. Another group includes the City Hospital, Free Hospital for Women, Charity Club Hospital, and St. Elizabeth's Hospital, while the Carney Hospital makes the medical centre for South Boston.

Intermediately are placed the largest dispensary, in Bennett Street, and the branch of the Lying-in Hospital, and toward the northeast and southwest respectively, the North-End or Charter Street Dispensary on the one hand, and the Children's Hospital and the new Free Hospital for Women on the other.

The location of the larger hospitals is seen, therefore, to be favorable in reference to the present distribution of population, which must, however, require in time another medical centre, as it grows westward, and as favorable for purposes of clinical instruction as is anywhere possible unless it be in the case of hospitals directly connected with medical schools.

An additional ambulance was purchased during the year, making four in service. One was stationed in Division 11, to be used in case of accident to any of the others, and to respond to calls for ambulance service in that immediate vicinity. This ambulance rendered good service on the occasion of the accident on the Old Colony Railroad, at Quincy, August 19th.

Ambulance No. 1 made 323 runs, and conveyed 283 persons to the hospitals, 21 home and 11 to other places. Ambulance No.

2 made 469 runs, and conveyed 411 persons to the hospitals, 42 home and 16 to other places. Ambulance No. 3 made 74 runs, and conveyed 56 persons to the hospitals, 15 home and 1 elsewhere. Ambulance No. 4 made 20 runs, and conveyed 17 persons to the hospitals, 2 home and 1 elsewhere.

The question of location of the hospitals naturally suggests an inquiry into the means of transportation of the emergency cases which form an important part of their *clientèle*, 530 accident cases having been received at the Massachusetts General Hospital, and 888 at the City Hospital in a year. To meet this need each hospital has an ambulance service of its own; and there are, in addition, four police ambulances stationed as follows: No. 1 at Station 1, Hanover Street; No. 2 at Station 4, La Grange Street; No. 3 at Station 7, East Boston; No. 4 at Station 11, Dorchester; or one ambulance to four stations. The work done by these is shown by the preceding extract from the Report of the Board of Police — now in the hands of the printer — and needs no comment.<sup>10</sup>

It is impossible to review this provision for the care of the sick poor without appreciating the benefit which should accrue to humanity other than that immediately afforded in the relief of the individual; with each decade the educated physician is becoming a more important factor in the community, dealing directly with its most valuable possession, and, appreciating a double duty in the prevention as well as in the relief of human suffering, he must be at once both a student and a teacher as the necessity of his moral existence.

That the hospital has a function other than that for which it was originally founded, has come to be recognized more and more with that advance in medical education which tends to substitute the object lesson for the book, and to stimulate the appreciation of a fact by direct appeal to the sense perception of it, a change in education which is steadily taking place all along the line and the sense of which is nowhere better put than in what Professor Hyatt says of public museums and gardens.<sup>11</sup>

"Books have and perhaps always will occupy a very important part in education, but it must be remembered that all instruments with which humanity has done its work have suffered change, and have been greatly modified or wholly replaced by others. Books are instruments for recording mental conceptions and can, as a rule, convey only such ideas of the things of which they treat, as may be possessed by the author at the time of writing. He, having seen what he has described or discussed, may possibly have definite conceptions and write well, but the reader has not had the same advantages, and the impressions made upon his mind are necessarily fainter, and may be, owing to defects in the author's mode of treatment, or his own inability, very slight and transient. Books used in the schools have long been considered unsatisfactory by many of the best teachers. These recognize that printed pages cannot convey knowledge in sufficiently definite and impressive form unless used in connection with pictures or models or preferably the things themselves. In other words the visual element in education is becoming more and more important every day, and in many of the finest European and American schools the objects themselves are extensively used.

"Natural objects are Nature's books, the only ones

<sup>9</sup> The idea is taken from a similar map prepared by Professor John Chiene, of Edinburgh.

<sup>10</sup> Reference should be made to the interesting paper on the need of an Emergency Hospital, and the accompanying remarks published in the Boston Medical and Surgical Journal, February 5, 1891.

<sup>11</sup> Atlantic Monthly, Jan., 1891. Houghton, Mifflin & Co., Boston.

that hold within themselves the infinite sources of knowledge, and never need to be reissued in improved editions. They can furnish food for study to all minds, whatever their capacity, and it is only a question of time when the advance of human learning will create even a greater demand for them than there is now for what is written about them."

What is here said may be well taken and applied to the modern study of medicine: "The most essential part of a student's instruction is obtained, as I believe," says Dr. Holmes, "not in the lecture-room but at the bedside; nothing seen there is lost. I do not hesitate to say, it (clinical teaching) is more essential than all the rest put together so far as the ordinary practice of medicine is concerned, and this is by far the most important thing to be learned, because it deals with so many more lives than any other branch of the profession; so, of personal instruction, I think it has many advantages of its own."<sup>12</sup>

"What we want to hear is the truth as it has been experienced by the person who speaks, not what has been felt by some writer in the dusty past, although that truth may be just as true and as eloquently expressed."<sup>13</sup>

"What I want above all things" said a third-year student, "is to touch a patient"; and between the Rev. Thomas Hyde and the medical student, lie the two important facts which make the value of clinical instruction,—the personal influence of an enthusiastic teacher and the personal experience of a living fact.

Very nearly twenty years ago a brilliantly aggressive member of the Massachusetts Medical Society asserted that specialists were the officers, and general practitioners the rank and file, of the profession. This sentiment was by no means heartily re-echoed at the time, the medical specialist being then a comparative rarity, and the "rank and file" largely in the majority. Nor has this assertion, it is safe to say, found more favor in the later years, although the specialists have greatly increased in number,—for, with the subdivision of labor, and the exploration of hitherto comparatively unknown regions of research, there has come a sense of interdependence and community of interest, which is a most valuable and wholesome thing in either an army or a brotherhood, and from which springs naturally an appreciation of the necessity for community of knowledge.

To carry out the military simile in another form, while the general practitioners constitute the main body and strength of an army, the officers of which are all promoted from the ranks, the specialists form a skirmish line of volunteers going out in different directions to explore, to gather information, and, most important sequence, to report back to the main body the line upon which it may, after corroborative investigation, with safety advance.

One of the duties, therefore, of the specialist, and particularly of the specialist with material for investigation at his hand, is *to investigate*, and another of his duties is *to teach*, in so far as the gift of teaching has been given him, and to report as simply and as plainly, as he can that which he has learned, since the knowledge which he has acquired is not his, but is held in trust as the property of that main body of which he is one of the rank and file on special service.

It is no longer, therefore, only for the undergraduate

in medicine that provision must be made; the elaboration of investigation which calls to its aid the collateral sciences necessitates division of labor in teaching as well as in practice, and this relationship between the teacher and the pupil, the hospital doctor in town and the general practitioner in the country, is being practically recognized by the recent establishment of post-graduate schools, as they are called, or graduate departments of already existing medical colleges, in the larger cities of the United States.

The instruction demanded in such a school must of necessity be as different as is the character of the students; the undergraduate must have his work in a great measure mapped out for him during a definite period of study; the graduate has already had this, and in addition the practical schooling which has taught him pretty succinctly, if he is the sort of person to profit by further instruction, what his needs in that direction are, and he applies for longer or shorter, single or combined courses, accordingly.

A medical graduate department, therefore, means provision for elective and almost exclusively clinical instruction with an independence in the arrangement of its courses and an elasticity in its government which would be quite incompatible with the successful existence of an undergraduate school. Provision must be made not only for such definite courses, annually repeated, as shall form the basis of its teaching and meet the needs of a majority of graduates, but for such special courses as occasional clinical opportunities or recent investigations on the part of individual teachers may suggest, a form of instruction which, coupled with freedom in the choice of assistants and material, stimulates the efforts of the instructor, brings the stronger men, both as teachers and as students, to the front, and has laid the foundation of more than one successful school.

To maintain such a department on a plane with the advancing standing of Harvard Medical School, which already takes the lead in the United States, both as to its admission requirements and the quantity and quality of its instruction, and to be able to supply instruction of a commensurate quality to practitioners who are now in increasing numbers coming to Boston for that purpose, it is important, not only that the relationship between the hospitals and the teachers in the profession should be maintained and these bonds strengthened, as has lately been done by the Board of Managers of the Massachusetts Charitable Eye and Ear Infirmary in their wise and generous encouragement of the use of the institution for clinical teaching,<sup>14</sup> but that provision should be made, as has already been suggested in such thoughtful papers as the last annual address before the Massachusetts Medical Society and the publications of the present Superintendent of the

<sup>12</sup> Extract from the Records of the Massachusetts Charitable Eye and Ear Infirmary, Managers' Quarterly Meeting on May 1, 1888.

<sup>13</sup> *Ibid.*, That the Board of Managers has received with much gratification the unanimous proposal of the Board of Surgeons that the use of the Aural Clinic should be favored for the purposes of instruction in connection with the Harvard Medical School or otherwise, that it cordially sympathizes with the desire of the Board of Surgeons to extend the usefulness of the Infirmary as widely as possible; and, accordingly, it requests the aural surgeons to take the necessary steps to arrange for such instruction, in addition to that already given students, as shall not interfere with due attention to the patients, whose interests should always be of paramount importance; that it would also be glad to receive in writing from the aural surgeons the plan proposed to be pursued, with such other information as they may have to offer, and that the President, Mr. Augustus Lowell, and the Secretary be a committee, with full powers to adjust details; and, finally, that it would be pleased to have the Board of Ophthalmic Surgeons consider the feasibility of establishing a similar course of instruction in its department."

<sup>14</sup> See a full report, Dr. W. Holmes, 1887.

<sup>15</sup> See a full report of Rev. Thomas Hyde, Boston, May, 1890.

State Almshouse at Tewksbury, for further hospital accommodation, and especially for important departments, as that of skin diseases, for instance, for which there is not a single special ward in any hospital in Boston, and for the treatment and study of certain contagious diseases, the persistence of which uncontrolled is a disgrace as well as a menace to the community.

Of earnest and willing teachers there is apparently no lack, since of the one hundred and ten physicians attached to the Eye and Ear Infirmary, St. Elizabeth's, Carney, Massachusetts General and City Hospitals, and the Boston Dispensary, sixty-one, or about fifty-five per cent, are engaged in medical instruction, two-thirds of this number being connected with Harvard Medical School, in which it is now arranged to have instruction continuous throughout the year, and available for both under-graduates and graduates. The medical profession is nowhere more at one in its sentiment in regard to advanced medical education and in its appreciation of what that means for public benefit, than in Boston, and in this community there is needed only a better knowledge of its work and purposes to bring it substantial encouragement.

#### SEWAGE: APPLICATION TO LAND THE BEST METHOD OF TREATMENT.<sup>1</sup>

BY HENRY J. BARNES, M.D.

It is now nearly seven years since I had the honor of reading before this Society a paper on the epuration of sewage by irrigation and agriculture, wherein I affirmed this to be the only known method by which complete purification could be accomplished, fulfilling sanitary requirements possessed by no other, besides being the most economic. The members of the medical profession who took part in the discussion admitted the possibilities of purification by this treatment, but doubt was generally expressed as to the advisability of our adopting it, either from a sanitary or an economic point of view. Among the engineers it received little or no favor, with the exception of one, who spoke favorably of the Pullman sewage farm, while maintaining that sewage does not act as other manures do, and it is therefore necessary in alternate years to suspend irrigation, and that the dry weather flow of sewage of Boston south of the Charles, would irrigate 15,000 acres. Another referred to our rigorous climate as being an obstacle. Another to our peculiar topography, there being no prairies favorably situated. Another said sewage is not applicable to hoed crops, and that Italian rye grass is not adapted to our climate, and it seemed as if the writer of the paper had informed himself chiefly by reading, which has embraced only one side of the question. A year later, this engineer recommended this system to a town not far from Boston, and mentioned Italian rye grass as one of the most desirable crops.

#### GLASGOW.

With the object of ascertaining how far actual experience, and the opinions of recognized authorities sustain the views expressed at the meeting, early in July, 1889, I visited Glasgow. This city discharges its

sewage into the tidal water of the Clyde, twenty miles from the mouth of the river. In consequence of the terrible offences created and the constant expense for dredging, the city has under consideration a plan for withdrawing the sewage from the river, and Mr. Young, the inspector of cleansing, after visiting Nottingham, Croyden, Berlin, Paris, and other places, has reported to the municipal committee on health, that it is quite practicable to purify, and at the same time utilize the sewage by irrigating the plains of Cart and Gryffe. All the household wastes of the present population of 750,000 including 118,000 water closets, could in his opinion be taken care of on 4,500 acres of land (for which he proposes to pay \$600 per acre) at an annual expense to the city above estimated income from the farm, of only about \$30,000.

Dr. Russell, the officer of health, and a well-known sanitarian, devoted the greater part of a day in conducting me about the town. He emphatically declared soil treatment to be the only means by which the sewage of Glasgow could be disposed of without seriously objectionable features.

#### EDINBURGH.

I visited the Cragentinny Meadows in company with Mr. Archer, health officer of Leith. On a part of the 450 acres belonging to Mr. Christie Miller, the sewage of Edinburgh has been utilized for over two hundred years, with the sole object of profit, no other fertilizer being employed. All the land is underdrained. There are forty acres of sandy soil, thirty of red clay, and one hundred and thirty of loam, receiving the sewage by gravitation. At the expense of the owner the sewage is pumped on other parts of the farm. Fifty years ago the lowest field was a barren strip of sea-sand, but now yielding enormous crops of grass. The manager stated that within his memory none of the land had been plowed or re-seeded. Two men are employed, one by day and one by night, to attend to the distribution, and keep the open carriers free. The grass is sold at auction at the beginning of each season, and cut as many times as the purchaser considers it for his advantage. Four to six crops are taken each year and used in stall feeding; \$125 to \$150 per acre is the usual price for one season's crops. The land takes all the dry weather flow from what is known as the old part of Edinburgh, and is equivalent to one thousand persons to the acre, and the water consumption thirty-nine gallons per capita. This makes a volume of sewage far exceeding the absorbing capacity of the soil, and much flows over the surface, to the final discharge, which is at times very foul. Many of the open ditches were also offensive, and indicated either neglect or parsimony on the part of the owner, and for this reason the municipal authorities of Edinburgh had appealed to the courts with the object of gaining control. A decision of the highest had just been rendered declaring the vested rights of the owner of the land unsalable. The health officers of Edinburgh and Leith, both admitting hostility to the farm, could not say the district was otherwise than the most healthful, and no testimony could be obtained, that any injury had ever resulted. The surgeon in charge of the government barracks, separated from the farm only by the railroad, testified that the health of the soldiers and their families was excellent, and that during the cholera epidemic at Leith and Edinburgh in 1865-66, not a case

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Massachusetts Medical Society, Suffolk District, January 21, 1891.

occurred on the farm or in the vicinity. An amusing incident in the defence, was the exhibition of the *fac-simile* of four grave-stones, to prove the great age attainable by residence on the farm.

Dr. Littlejohn and Mr. Archer both expressed to me the opinion that soil treatment was the most satisfactory treatment of all methods known for the disposal of sewage.

#### LIVERPOOL.

Liverpool discharges sewage in the tidal estuary of the river Mersey. I did not discover any offensive feature, except that the water about the magnificent Victoria docks was highly discolored. Dr. Hope, the only health authority I met in Europe who spoke favorably of this method of disposal, declared the system to be entirely satisfactory. By accident I learned from a captain of one of the ferry-boats, that a bar was forming at the entrance of the harbor from sewage deposit, a result which the royal commission says may always be anticipated from the action of sewage in contact with the sulphates of sea water.

#### MANCHESTER AND SALFORD.

The river Erwill, which separates these large cities, receives the sewage of both. It rivals the Clyde in its offensive condition. Dr. Tatham, the health officer, informed me that the sewage must soon be withdrawn, and that soil treatment was the best and only known method by which it could be disposed of without objection.

#### BIRMINGHAM.

By the courtesy of Dr. Hill, health officer of the district, I was furnished with every facility for inspecting the sewage farm of the city, where the sewage of 650,000 people, amounting to 17,000,000 gallons per day, is purified and utilized on 1,260 acres. A partial treatment by lime is made necessary here, as the sewage has an acid reaction. The land has a comparatively deep soil of black loam, overlying a gravelly subsoil. It has been levelled and underdrained. With the exception of offensive odors about the precipitation works, I was unable to find any evidence of the presence of sewage, except to see it running in the open ditches, and observe the magnificent crops of vegetables growing on the land. I asked Dr. Hill if the volume of liquid or the putrescible organic matter contained in the sewage, fixed the limit of the soil for purifying purposes. He replied, "It is almost impossible to over-fertilize, but an easy matter to overburden the capacity of land to dispose of water." The city pays £20 rental per acre a year for land leased, and the average price paid for land purchased was \$760 per acre. To operate the farm it costs about \$135,000 a year, and the income from the sale of produce amounts to about \$100,000 a year. This is a remarkably satisfactory result, in view of the fact that the water has little or no value for agricultural purposes, owing to the character of the soil and climate. The engineer says, "the great item on the credit side of the account, is the satisfactory disposal of the sewage."

#### LEAMINGTON.

Dr. George Wilson, health officer of the district, conducted me over the farm of Lord Warwick and to the new hospital for contagious diseases in the centre of the town. In purchasing the site, provision was

made for the exclusion of sewage from the immediate vicinity, as the management of the farm had become very careless, since Mr. Tough had left to take charge at Birmingham. Signs of neglect were apparent in many places. The open carriers were old and filthy, the banks were broken in many places, where pools of stagnant sewage caused much offence. In other places the soil was washed from the roots of vegetation, by breaking through the embankments on the hill sides. The weeds were abundant and crops poor. This is the farm I described seven years ago as an example of profitable utilization, after the payment of \$2,000 a year for 1,000,000 gallons a day, delivered at the highest point of the land. It cost about \$35 an acre, including drainage to the depth of four to five feet, to prepare the land for the sewage. The surface was altered but very little, the position of the carriers being governed by the natural lay of the land; "a plan preferable," says Peregrine Birch, "to the common practice of piling down to the surface and robbing it of soil, till it can be irrigated from channels drawn with a parallel ruler." Dr. Wilson said the farm was, and now could be, conducted in a profitable and unobjectionable manner, and that he esteemed it the best known means for the disposal of sewage.

#### CROYDEN.

This is a city of 94,000 population, taking a water supply of thirty gallons per capita from deep wells, surrounded by the dense population of the town. The dry weather flow of the sewage amounts to 3,500,000 gallons per day, and in time of storm a maximum of 9,000,000 gallons is reached. About 500 acres of stiff clay soil without underdrains, is employed for the purification of the sewage, which is reached by gravitation, except a field of about 80 acres, reached by pumping, the motive power being the sewage discharged on the lower fields. Owing to the character of the soil the sewage flows over the surface from field to field and in time of storm discharges into the river Wandle clarified, but containing considerable sewage matter in solution, not, however, enough to influence fishing in the river at any time.

The land is generally low and therefore not likely to be benefited by sewage, except from the fertilizing properties it contains. A gentleman who contracts for most of the grass produced, feeds a herd of 150 cows for milk, which is sold in London.

The name of Alfred Carpenter is well known to you as a high authority in sanitary science. In 1856 his influence established this farm, and it is now twenty-four years since he introduced this method of disposal to an assembly of men of science, especially called to consider the subject of town drainage. His last public utterance on the subject was at the annual meeting of the British Medical Association in 1888, when he said: "It is difficult to prove a negative. I assert that disease germs are of two kinds, corresponding with active germs and resting spores. Eggs hatched and growing, and eggs unhatched. The hatched eggs are rapidly destroyed by the physical conditions under which they arrive at the farm. Exposure to air, a lower temperature than that necessary for warm-blooded creatures, absence of pabulum, and presence of injurious gases soon destroy their life; but the resisting spores (unhatched eggs) are more persistent. They certainly arrive on the farm and it might be expected they would do mischief, and so they do

(and would) if the sewage is not immediately applied to the land. But then, if arrested, Nature comes to our rescue, and destroys them by the sulphuretted hydrogen, which is engendered as soon as putrefaction is rampant; but putrefaction destroys the chance of a satisfactory financial return from the use of the sewage, and it is not to be encouraged. As soon as the resting spores come in contact with the spongioles of plant life, they are taken up with avidity, and taken in as food most energetically, much as human beings take in oysters when they get the opportunity. Some classes of plants which I have presumed to name carnivorous, among which I place rye grass, do assimilate these germs in the most rapid and satisfactory manner, so that no particle escapes their devouring power, and the effluent, so far as my observation goes, is absolutely free from their presence. . . . If sewage is kept moving it may travel any distance. The farm may be forty miles from the town producing it, but if so, the cost of transit will be large, which may be counterbalanced by cheaper cost of land. . . . I earnestly recommend sewage farming as applicable to all water-closet towns without exception, and feel sure it will be far more satisfactory than for it to be sent into the Thames, the Mersey or the Clyde, to the gradual destruction of our water-ways, and the removal from our midst of that which will give sinew, muscle, bone and marrow to the people." In a long interview with Dr. Carpenter, he maintained these views with great force, but lamented that the management of the Croyden corporation had been delegated to politicians ignorant of sanitary science, who were wasting the products of the farm by preventing consumption on the land, and thus playing into the hands of the rich cow-keeper and others, to the pecuniary disadvantage of the city. This he pronounced a monstrous perversion of common-sense.

## LONDON.

I can add little to the information you now possess as to the effect of discharging crude sewage into the tidal estuary of the Thames. From every point of view it is a nuisance of gigantic proportions, a cause of sickness, an injury to commerce. Five million of dollars in addition to twenty-one million already expended, is now being employed in constructing a plant to treat the sewage with lime, sulphate of iron, and permanganate of potash.

Dr. C. R. Drysdale, senior physician of the Metropolitan Hospital, said of this scheme, "For years past the Board, against the advice of Lord Bramwell's Commission, has gone on tormenting the dwellers on the banks of the Thames, by pouring daily 150,000,000 gallons of sewage into the river, and are now adding a greater absurdity, namely, the erection of two enormous tanks at Barkin and Crossness, where a useless experiment with chemicals is to be made," and quoted Sir R. Rawlinson to the effect that this experiment will cost London ten millions sterling for no purpose. Dr. Corfield stigmatizes it as a probable waste of public money and accuses the Metropolitan Board with setting at naught the conclusions of the Royal Commission. Dr. Carpenter said it is the scattering of an immense sum of money on works which may become useless. The present health officer of London, Dr. Sherley Murphy, said to me, "The city will never have a satisfactory system until land is employed for purifying the sewage."

## PARIS.

I visited the irrigation fields at Gennevilliers in company with the members of the International Congress of Hygiene, on a hot, muggy day of August. With the impression that on a show day defects are not likely to be made prominent in an exhibition, I traversed the fields outside the paths through which the company was guided, but failed to find in any place the slightest indication of an offensive nature. With many members of the Congress, following the example of the chief engineer of the city, M. Bechmann, we drank freely of the effluent, being assured of its purity, both by chemical and biological examination. Late in the afternoon, at a dinner given by the city at a public hall of the town, all the fruits and vegetables were said to have been taken from the experimental farm of the city, the truth of which could not be questioned by those having the opportunity of seeing the magnificent growing vegetation in all stages of culture.

In the post-prandial exercises, representative men of science from many parts of the world, all pronounced the system a success in every feature, in eulogizing the memory of Durand-Claye, who, regardless of threats of personal violence by villagers apprehensive of total annihilation of value in their property after an unfortunate experiment resulting in flooding a large area, and covering the premises of many under several feet of sewage, blocked and obstructed by the municipal authorities, assailed by law-suits, opposed by nearly all the savants of France, had triumphed over all, and lived to see the little field of two and a half hectares which "at first appeared like an oasis in a desert" expand into beautiful agricultural lands embracing over sixteen hundred acres, by the voluntary action of the inhabitants, who were, at the time of my visit engaged in raising funds to erect a monument to his memory.

The town has increased in population since the establishment of the system in 1868, thirty-five per cent., and now numbers a little over 3,600, nearly all occupied in raising vegetables for the Paris market. The mortality rates for five years preceding the irrigation was 32 per 1,000 per annum, for the last five years it has been a little under 25. In 1882, when typhoid was epidemic in Paris, there was no increase in the number of cases at Gennevilliers, and not a case of cholera in 1884 when this disease was epidemic in the city. The financial results are no less satisfactory. The rental value being five times greater since irrigation, and justifies the hope entertained by the city authorities of profitable utilization in the forests of Saint Germain, where works are now being constructed on lands acquired of the State at a rental per annum of \$24 per hectare, with the privilege of buying at \$820 per hectare.

(To be continued.)

STREET ACCIDENTS IN LONDON.—The Home Secretary stated in the House of Commons, in answer to a question put by a member, that in the past year 5,330 persons were injured, and 110 killed outright by vehicles in the streets of London.

"DOCTOR," said little Emily, "do you know that a baby that was fed on elephant's milk gained twenty pounds in one week?"—"Nonsense!" exclaimed the doctor, and then asked: "Whose baby was it?" "It was the elephant's baby," replied little Emily.

## PROGRESS IN DERMATOLOGY.

BY JOHN T. DOWEN, M.D.

## THE KOCH TREATMENT FROM A DERMATOLOGICAL STANDPOINT.

VERY little has thus far been published by dermatologists of acknowledged competency, on the subject of the Koch treatment. They have contented themselves, as a rule, with a corroboration of the remarkable effect that the injections have on many cases of lupus—more than that, the very nature of the morbid process, which is formidable chiefly from its inevitable tendency to recur after all appearances of disease have been removed, forbids us to affirm before the lapse of many months.

It is to the clinics of Paris and Vienna that we look with eagerness for a report of the progress of the cases treated, for in no other place in the world are the opportunities for investigating any treatment of cutaneous tuberculosis, so extensive. In Paris at the famous St. Louis hospital for skin diseases, ninety patients with lupus in its various forms are being treated and observed by a commission of the dermatologists connected with the institution, all of whom have had especial and abundant experience with the disease, and with the former modes of treatment. A preliminary report was to have been made to the French society of dermatology at the February meeting. In Vienna, Kaposi, whose opportunities for studying the treatment are equally great, after a preliminary visit to Berlin began the treatment of thirty-two lupus cases at the same time. He also made injections in numerous patients who were suffering from skin diseases, manifestly not tuberculous, and claims to have obtained a local reaction of the diseased tissue, together with constitutional reaction, in a case of leprosy, in a sarcoma of the pharynx, in a lupus erythematosus, and in two cases of syphilis. In fact, there seems to be no doubt now that the agent cannot in all cases be relied on as a means of differential diagnosis. Numerous cases of leprosy are reported by other observers, as showing a general and local reaction under its use, and in ten cases of lupus erythematosus that have been reported, a general reaction was noted in all, a marked local reaction in several.

Thibierge, of Paris, whose competency to judge of cutaneous changes cannot be questioned, reports in two articles in the *Annales de Dermatologie et de Syphiligraphie* the results of his observations of the treatment in the Berlin hospitals. These articles seem to have been written in a cool, impartial spirit, offering in this respect a marked contrast to many of the publications of the last three months. He asserts that the anchioration produced in cases of lupus is incontestable, having been observed in France, England and America, as well as in Germany. The improvement is most rapid and marked in the ulcerated forms, and this accords with the surgical observation that the best results are obtained in cases of open, fistulous lesions. A rapid and remarkable diminution of the elephantiasis-like infiltration that often complicates lupus, has also been observed in some instances. But no one has as yet published a case which can be considered as *healed*, that is to say where all the lupus nodules without exception have disappeared. The writer declares that he knows, on good authority, that the first patients treated in Berlin are in an almost stationary state, and that none of them has been freed from all his lupus

nodules, even temporarily. He concludes that from the evidence now before us (January 25, 1891) Koch's method produces in many cases of lupus a marked improvement, with a rapid cicatrization of the ulcerated portions, but it has not yet produced an even *apparent* cure, to say nothing of one that we may venture to regard as *permanent*.

Wickham, whose name is familiar to dermatologists from his studies of porosporosis and Paget's disease, concludes a letter written to the *British Journal of Dermatology* on the treatment of lupus at the St. Louis Hospital, as follows:

"I will not anticipate anything that might be said, or that will be shown at the next meeting;<sup>1</sup> but I can even now announce to my readers that unfortunately it does not appear as if the final results would be very favorable. After watching the treatment for six weeks, I have not seen a single case cured, or even one that has an appearance of a complete cure.

"Where the lupus has very much improved, a close examination shows a number of lupus nodules under the cicatrices. The lupus nodules and ulcers which are often quickly healed by thermo-cautery or scarification, are just those which derive the greatest benefit from the effects of Koch's lymph. The ulcerations become cicatrized, the nodules are diminished, but the lupus elements remaining appear absolutely stubborn. I have seen new appearances of lupus nodules, notwithstanding treatment, on the borders of old lupus. In fact, generally speaking, up to the present time, the great majority of lupus cases so treated do not show much difference after the treatment. Some have been improved, others have continued to spread and increase. But I do not wish to say more at present, but refer my readers to my next letter.

"We trust that the effects of the lymph during the month of January (second month of treatment) will have a more favorable result, and that the final decision of the Commission will be more satisfactory."

## PATHOLOGY OF ZOSTER, VACCINIA, ETC.

Pfeiffer<sup>2</sup> reports 117 cases of typical zoster, which were placed at his disposal by the medical club of Thüringen. From a careful study of the exact topography of the lesions in these 117 cases he concludes that the eruption corresponds more to the ramifications of the cutaneous arteries than to those of the nerves, and that this localization is especially emphasized in zoster pectoralis. A close examination of these cases proves that a prodromal attack of fever is almost universal, and neuralgia exceedingly frequent, and that in some cases atrophy of the muscles and sensory disturbances were noted. He concludes that zoster is probably not, as is generally believed, a trophoneurosis, but that the eruption is caused by a plugging of the capillaries of the affected part with lower organisms that are circulating in the blood. Attempts at cultivation from the contents of the vesicles in five cases, detected solely the presence of secondary colonies, whose inoculation, as well as that of the fresh fluid from the vesicles, failed to produce zoster.

On the other hand he finds specific cell forms in the rete layers, that have not hitherto been described in herpes zoster; they resemble the plasma cells somewhat, although not identical with them, and are also found in variola, ovine, vaccinia and varicella, but not

<sup>1</sup> Of the Société Française de Dermatologie et de Syphiligraphie.

<sup>2</sup> L. Pfeiffer. *Iena*, Gustav Fischer.

in erythema multiforme, cheiro pompholyx, etc. The author has found similar appearances in the epithelioma contagiosum of birds, and in the kidney of several varieties of snails. His conclusions are that zoster is an infectious disease, which produces its external manifestations by the agency of the blood channels.

The same writer has published a short work on the pathogenic protozoa with thirty-four illustrations in the text and one plate.<sup>3</sup> Induced by his belief in the infectious character of zoster, he was impelled to study the subject of the protozoa generally; and an opportunity was offered him in the laboratory of Professor Bütschli, one of the highest authorities on this subject. Comparative observations on cell hypertrophy caused by chytridiaceae, sporozoa, and flagellati have confirmed his opinion, that a foreign organism is to be found in the epithelium of the vesicles of zoster and of variola. His publication of one hundred pages is devoted first to comparative observations on cell hypertrophy caused by animal parasites as seen in the lower animals, and finally to a consideration of the affections of the human body that may be referred to the presence of these organisms.

In the contents of every fresh zoster vesicle examined in a one per cent. salt solution, are to be seen large cells of a greenish, glistening appearance, rounded, egg-shaped or drawn out at one end into a pear-shape, with a large nucleus and transparent protoplasm. They are recognized at once by their peculiar, glistening appearance. In places these round cells are seen to be enclosed in epithelial cells on the lower surface of the outer skin that has become separated from the mucous layer. Some of the epithelial cells contain but one of these foreign bodies; in larger flat, epithelial cells several may be seen. The nuclei of the "parasite" cell exhibit often a division into a number of segments (sporulation?) and some of the segments seem to be surrounded by a thin clear ectosark. The larger "parasite" cells are surrounded by an ectosark which exhibits active motion, quite similar to what takes place in the myxosporidiae. The smallest of the cells found in the serum show upon the warmed stage undoubted amoeboid changes in their contour.

None of these appearances could be found in the blood of the patients, although Pfeiffer considers that the vascular system is the carrier of the contagion. Similar cell forms are seen in variola, vaccinia, ovine, and varicella vesicles. The writer is inclined to the view that these parasites belong to the myxosporidiae rather than to the coccidia, and while finally expressing some reserve on the subject of their significance, he calls upon both physicians and zoologists to undertake their study, in order that their exact place in zoology may be determined.

#### NEW DERMATOLOGICAL PREPARATIONS.<sup>4</sup>

(1) The salicylate of mercury is an excellent anti-specific, that is quickly taken up by the blood and eliminated by the kidneys. To this speedy absorption is due the stomatitis and gingivitis that appear so quickly after its ingestion. There is much irritation of the stomach and intestinal tract, and hence opium should be prescribed with it; on the whole, Schwimmer considers the salicylate of mercury the most effective of the preparations of mercury that are used internally.

(2) Oxynaphthoeic acid produced no effect on syphilitic and venereal ulcers. The reaction caused by the drug was so severe that it had to be given up. In scabies good results were obtained. The formula used was as follows:

Acid naphthoeici	
Creta albae	ss 10
Sapon virid	
Xanngt	100

Three or four inunctions only are necessary. No favorable results were obtained in vegetable parasitic diseases, as no reaction of the skin is obtained from it. In prurigo, a ten per cent. ointment for adults, and a five per cent. ointment for children gave good results.

(3) Anthrarobin was tried in psoriasis, tinea trichophytina, eczema marginatum, and pityriasis versicolor. It was found exceedingly unsatisfactory in psoriasis, but in the vegetable parasitic affections of great value. A ten per cent. anthrarobin-lanolin ointment was applied twice daily for ten days when a perfect cure was attained. The disadvantage of anthrarobin is that it stains the clothing.

#### ACUTE CONTAGIOUS PEMPHIGUS.<sup>6</sup>

Two forms of acute pemphigus are accepted by the greater number of authorities. The first form develops like an acute infectious disease with intense fever, in company with which a disseminated eruption of bullae appears. After repeated exacerbations the affection either heals or ends fatally.

The second form is much more benign. It is called pemphigus neonatorum, as it only affects adults exceptionally, when infected from the children. It is distinguished from the first variety by its essentially benign course, and by its contagiousness, appearing usually as epidemics in institutions. For many years this affection has been almost endemic in the hospital at Copenhagen, and Faber's interesting paper is based upon a careful study of one of these small epidemics.

A few sporadic cases had shown themselves during a period of several months, when suddenly within two days, three children who occupied adjoining beds were taken ill. In two of the cases there appeared bullae of the size of a mark piece, first upon the chin, later over the greater portion of the body. The head and neck were much more extensively affected than the body. The third child developed but a single bulla on the leg and was completely well in a few days. There was a slight rise of temperature in these cases, but the constitutional reaction was very mild. The affection lasted about two weeks.

Investigation showed that the mother of the child first attacked had an eruption upon the cheek that in appearance and course could not be distinguished from an impetigo contagiosa. She had nursed her own child, and also the second child a short time before the eruption appeared, and it will be remembered that both children were first affected upon the chin. The third child lay in the next adjoining bed. This pointed to an infection of the two children by the woman who had nursed them, and this theory was strengthened when it was found, that after the second child had gone back to its own mother, the latter developed two typical patches of impetigo contagiosa. As there could be no doubt that the affection of the children was a typical pemphigus as repeatedly observed in small epidemics in the same institution, the writer concludes that there is good reason to think that pemphigus

<sup>3</sup> Die Protozoen als Krankheitserreger. Jena, 1890.

<sup>4</sup> Schwimmer: Archiv. f. Derm. u. Syph., 1890, s. 738.

<sup>6</sup> Kuntz Faber: Monatsh. f. prakt. Derm., Bd. X, No. 6.

neonatorum and impetigo contagiosa represent the same disease, appearing under a different form, at different periods of life. For this view he finds support in various ways. In the first place he points out that there is a primary bullous stage in impetigo contagiosa before the yellow crusts have formed, and that there are epidemics of acute pemphigus in which crusts similar to those in contagious impetigo are seen in some of the cases. Furthermore there is so great a difference between the epidermis of an infant and that of an older child, that it ought not to excite surprise that the same cause should produce different appearances. For example, the scaling "psoriasis palmaris" of syphilis in the adult, corresponds to the syphilitic pemphigus palmaris of the infant. Other points of similarity are that both pemphigus neonatorum and impetigo contagiosa are benign affections; both are occasionally accompanied by elevation of temperature and malaise at the outset; both run a course of from four to six weeks, and both are contagious. The susceptibility appears greatest in infants and neither form readily grafts itself upon the adult.

For all these reasons he considers it impossible to draw a sharp line between the two affections. If the cases are observed in lying-in hospitals, where very young infants are in the majority, they are called pemphigus, even if in some cases there is a formation of crusts; if they are observed in families or in out-patient services, the number of older children is greater, and they are called impetigo, even if there are no crusts in some instances. Confusion will be avoided in the future by giving up the names employed at present, and calling all cases pemphigus contagiosus, as there is but one pathological process.

## Clinical Department.

### CASE OF A MAN STRUCK BY LIGHTNING; RECOVERY.<sup>1</sup>

L. M. PALMER, M.D., SOUTH FRAMINGHAM, MASS.

At two o'clock P. M., on the 28th day of last May, I was summoned hurriedly to attend a man struck by lightning.

I found a man thirty-six years of age, whom I had personally known for a number of years, who had previously always been remarkably healthy, strong and vigorous. I was probably at his side in fifteen minutes after he was struck. At the time of the accident he was mowing on the State muster-field with a two-horse mowing machine, and the same bolt that struck him at the same time struck and killed instantly his off horse.

The men working with him and near him said that he did not fall from his machine, but that his head simply tipped backward. The man who lifted him from his machine claims that he received a very decided shock from so doing, but I cannot understand how this could be possible. They further said that at first he did not breathe, neither could they feel any action of the heart at the wrist or the side.

When I reached him his pulse was 100 and weak, but regular; the respiration was 10 and stertorous, the mouth and throat being full of mucous, causing

the gurgling sound often heard in the dying. The pupils were widely dilated, eyes fixed, staring and insensible to touch, general muscular rigidity, with thumb of left hand thrust in, body warm but extremities cold, with no moisture on surface of body and no involuntary discharges.

I gave him at once, subcutaneously, injections of brandy and aromatic spirits of ammonia, and repeated it at intervals, rubbing him briskly in the meanwhile. Gradually, but slowly, the pulse became slower and stronger, the respiration less stertorous, and in about half an hour he began to move, first his hands, then arms, feet, legs and body, until at the end of an hour he was moving as much as I wanted him to, and more, for he was soon writhing and twisting his whole body into all shapes and postures, at the same time making a great deal of noise in so doing, opening his mouth so as to show the greater part of his epiglottis. At the end of another half hour, and after the administration of one drachm of bromide of potassium, he quieted sufficiently for me to take him home in an ambulance wagon and place him under the care of his family physician, by whose courtesy I was allowed afterwards to see and examine the case, and thus make a complete record of it.

On arriving at his home he vomited and continued to vomit at intervals through the night, and for several days following. His first night was a restless one, still continuing to cry out at times, till about 4 o'clock A. M., when he first spoke, and a little later he recognized his friends and surroundings.

A more careful examination the next day showed the following conditions:

The bolt had struck the occipital portion of his head, cutting a gash one inch long and down to the bone, removed the hair beneath the cut to the neck, one inch wide, singed off the hair between his shoulders as if by a flame, burned a spot over his right scapula seven by nine inches to the first degree, blistered along the under side of right arm, and burned deeply below the elbow over the fleshy part of the forearm, beyond which no mark could be seen. His straw hat was a new one, and the crown was literally destroyed. It is my opinion that the bolt after striking his head divided, the main part passing down the right arm and along the wet reins to the horse that was killed. I think the other portion must have passed down his spine and left leg, for there was a deep slough in the external portion of the calf of the left leg, with pain, tenderness and weakness in the lumbar region, and the parts supplied by the branches from the lumbar plexus, the most pain being in the genital organs. The next morning after the accident, he recognized me, called me by name, and answered intelligently all questions, but he said, "I don't know anything." Pulse, 60 and full, respiration 20, and temperature normal.

I will not detain you with the details of his recovery, but would briefly summarize as follows:

He made a slow but gradual recovery, vomited at intervals for three or four days, bowels constipated, no pain in head, but a confused feeling and loss of memory, disturbed by noises, considerable deafness, especially of right ear and ringing in the ears. Pulse normal, one degree of fever for a few days, bitter taste in mouth, eyesight normal, urine normal, general and marked prostration. Right arm and hand almost powerless. Pain, limited chiefly to the lumbar re-

<sup>1</sup> Read before the M.D. Soc. South District Medical Society, 1890.

gion and genital organs. He first sat up after eleven days, and began to drive a team after ten weeks, and has driven for four weeks since, though not well able to. I have examined him again within a few days and find him still weak, and walking like a man with a "criek" in his back, complaining of pain and weakness in his back, pain in his testicles, and loss of sexual vigor, a weak right arm and hand, tenderness over right brachial plexus and nerves of arm and forearm, and tenderness over small of the back and glutei muscles. He also has great loss of memory.

### ANGIONEUROTIC ŒDEMA.

BY J. G. MUMFORD, M.D.

LAST autumn Dr. R. W. Lovett described three cases of acute circumscribed œdema occurring in his service at the Carney Hospital.<sup>1</sup> He says, "These cases were characterized by an acute and rapid swelling of one hand and forearm, which began without known cause and reached an enormous size without being accompanied by pain, local heat or constitutional disturbance." He then goes on to mention the prominent symptoms of this affection. "Slight occasional digestive disturbances, slight fever, occasional abdominal colic and watery vomiting; and negatively, no local pain or heat, as a rule."

This report suggested to me a case of Dr. M. H. Richardson's, of which I had the charge while house officer at the Massachusetts General Hospital last spring. The case furnished some valuable supplementary data of the symptomatology of this rare disease.

The patient was a young man of twenty, a bleeder of the most marked type, though there was no family history of hæmophilia. Four years ago he was said to have had a severe attack of purpura, and to have had a most alarming epistaxis, which ceased only when he had become apparently exsanguined. His life was then despaired of. There had been numerous slight hæmorrhages at different times during his life, always controlled with difficulty. His general health had always been good.

At the time of entering the hospital, last April, he stated that, two days before, a swelling had suddenly appeared on the right cheek, beginning in the buccal cavity near the lower molars, and that within twenty-four hours the swelling had reached the size of an orange. Little pain accompanied the swelling, but great discomfort on moving the lower jaw. There was general prostration. For twelve hours there had been practically no change except occasional slight oozing of blood into the mouth.

The patient was tall and of slight build, and there was evidently a very considerable constitutional disturbance. His temperature was 103° F., pulse 104 and feeble, respiration eighteen and labored. On the right side of the neck and jaw was a uniform swelling about the size of a large orange, centred about one inch and one-half anterior to the angle of the jaw, non-circumscribed, pale except for a few hæmorrhagic spots near its centre; not painful or tender; not hot; pitting slightly on pressure. One half of the lower lip was swollen to half again its normal size, purple and hæmorrhagic in appearance. There was a slight sero-hæmorrhagic oozing into the mouth from behind the

second molar tooth. The jaw was moved with difficulty. There was no œdema of the glottis, but stertor on breathing, due to dislocation of the larynx from pressure. The urine was not abnormal.

Rest in bed, cold local applications and morphia were prescribed. Preparations were made for a tracheotomy, but contrary to expectation the patient passed a good night.

Till 5 P. M. of the second day the swelling steadily increased, extending down nearly to the clavicle and running around the chin as far as the angle of the jaw on the opposite side; becoming constantly more tense and painful. Cyanosis increased greatly with very labored breathing. Immediate aspiration of the tumor was proposed at this time, but postponed from hour to hour at the urgent request of the patient and his friends.

Three hours later the tumor had perceptibly diminished in size, part of its contents of clotted and liquid blood having been discharged through a spontaneous opening into the mouth. Rapid convalescence followed. Large amounts of blood, serum and clots were constantly being discharged into the mouth. Five days later the patient went home. I saw him two weeks afterwards, when there was no sign of the tumor remaining.

The interest in this case beyond those of Dr. Lovett lies in the history of hæmophilia and former attacks of purpura. It is in them that Osler finds one of his most important diagnostic signs, and it is to that complication that the term *angioneurotic* is properly applied.

### New Instruments.

#### AN APPLIANCE TO FACILITATE THE INSERTION OF THE SOFT-RUBBER (NELATON'S) STOMACH-TUBE.<sup>1</sup>

BY GUSTAVE LIEFMANN, M.D.,

Attending Physician to Patients with Stomach Diseases, North End Dispensary.

IN the everyday use of a stomach-tube the soft elastic (Nelaton's) tube is by general agreement the one to be preferred. Although the hard-gum tubes enter the pharynx and œsophagus much more readily, they are at any rate relegated to the rarer cases of poisoning with suicidal intent, where, from obvious reasons, the application of a soft tube is not feasible. In all applications of a tube for diagnostic or therapeutic purposes we use the soft kind, as it is well-nigh impossible to do any mischief with them, and they "sit" much easier in the stomach, giving rise to less irritation or gagging than a hard tube. Still the introduction of a soft tube is at times, although generally not difficult, a source of great annoyance to both physician and patient. And why? Because for the passage of the instrument from the fauces to the beginning of the œsophagus we have to depend on the intelligence and docility of the patient. He has to swallow the tube and work it through the pharynx, and only then are we enabled to push it down to the cardiac orifice. Should the patient from some cause (awkwardness, nervousness, and so on), fail to swallow, as it happens in some exceptional cases, then we are helpless and have to give up the job.

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene of the Massachusetts Medical Society, Suffolk District, January 21, 1891.

<sup>1</sup> Boston Medical and Surgical Journal, vol. exxiii, page 209.

Now to overcome this difficulty I have during the last three months used a simple appliance, that served me exceedingly well.

Although I designed the stylet and had it made to suit my fancy, I must state that the conception of it I got from a lady patient, returning from Professor Leube, in Wurzburg, who told me that the doctor used some sort of a staff to steady the tube. The stylet is made of rattan, is about thirty-four inches in length, to fit that of the ordinary Nelaton, and to project besides one and a half to two inches at the proximal end, is well smoothed down, of the thickness of a No. 6-8 English catheter (according to the calibre of the tube), with one end curved like the beak of a metallic bongie, but of uniform thickness from one end to the other.

#### MODE OF APPLICATION.

The curved end of the well-lubricated stylet is inserted and pushed forward through the tube, until it arrives at the distal end of the latter, care being taken that no part of it protrudes through any one of the openings at the end of the tube. It is advisable to bend tube and stylet still more into the requisite curve before inserting in the fauces. This done, the tube, with the stylet sticking out at the proximal end, is cautiously inserted — like any other hard gum tube — into the fauces and pushed forward along the pharynx to a point corresponding with the lower border of the cricoid cartilage, or in other words, to the beginning of the oesophagus, when the stylet is withdrawn, and the tube slid down to the cardiac orifice without any further trouble. You see the soft tube is changed into a stiff one but for the short minute, during which it has to pass the pharynx; we remove the stylet, and have to deal with a soft tube during the remainder of the whole procedure.

I would warn against allowing the stylet to remain within the tube below the mentioned limit, as in the first place, we don't want to use a hard tube in the oesophagus, and second, the withdrawal of the stylet under this condition would be almost impossible. At any rate, our end in view — the overcoming of the difficulty to the passage of the Nelaton tube — is fully reached by using the stylet only as far as the pharynx extends.

I would claim, therefore, that the stylet fulfils all the requirements of the case, dispenses with the co-operation of the patient, and that there should never be any further failure, the patient being willing and there being no organic stricture present, in introducing a soft-rubber tube into the stomach.

### Reports of Societies.

#### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOL- OGY AND HYGIENE.

ALBERT N. BODDIE, M.D., SECRETARY.

Regular meeting, January 21, 1891. The Chairman, DR. E. G. CUTLER, was detained during the first part of the meeting and Dr. J. J. MINOT was chosen chairman pro tem.

DR. G. LUTHEMANN showed and described an

#### IMPROVED APPLIANCE FOR INTRODUCTION OF THE STOMACH-TUBE.<sup>1</sup>

which commended itself to all present.

DR. H. J. BARNES read a paper upon

#### SEWAGE: APPLICATION TO LAND THE BEST METHOD OF TREATMENT.<sup>2</sup>

The Secretary read a letter from Dr. S. W. Abbot regretting his forced absence, and propounding the question, How are we to apply sewage to land in places where no suitable land can be obtained?

#### DISCUSSION.

DR. J. A. JEFFRIES: In pouring out so much drainage on the soil it might be supposed that disease would result, but practical experience shows that it does not; and so far as I know there is no evidence that it ever does. When one considers the question closely it will be seen that this is in accordance with the ordinary laws of nature. In the first place very few of the pathogenic germs form spores in the body and the vegetative forms in passing through the drains and from exposure to sunlight are readily killed; and in these drainage farms they are put into competition with a host of other bacteria adapted to the surroundings, and following the law of the survival of the fittest they are very readily killed out. Those which form nitrates, etc., root and kill the others out and eat them up. These bacteria when they grow are not just like a leaf in the soil, a dry thing that forms chemical products, but form a sticky substance, and in that way they bind the soil together and catch a great many things that otherwise would slip through. It does not seem to me that there is any doubt that where the soil can be got that it is the safest way of disposing of the drainage. Drainage, however, in the rivers is a constant source of danger. An instance of this was the epidemic of typhoid fever in Providence a few years ago. And we hear of such things everywhere and at all times. In these farms we do not hear of them. I do not think there is any doubt that this is the best way of treating sewage.

COL. GEORGE E. WARING, JR., of Newport: I have listened with very great interest to Dr. Barnes's paper. I have had the advantage of examining a large number of the towns to which he has referred as disposing of the sewage by agricultural irrigation. I have visited Gennevilliers at different times since 1875, and have kept *au courant* of what has been going on there, and with the very serious objections by the people and by the Council of Paris. I have seen all of those objections removed and the greatest and most complete success demonstrated. My last visit was in 1889, when about two-fifths of all the sewage of Paris, including a vast amount of water used in washing the streets, was disposed of on these lands absolutely without offence, and with such result that the effluent was not only excellent drinking-water, but was shown by chemical and biological examinations to be more pure than the best drinking water of the city itself.

The question that seems most to interest the people of New England is, as to what shall be done with the sewage in winter. The first thought of all not familiar with the history of the work is that in a severe climate there can be no possibility of disposing of sewage in these months. I have a recent instance that is con-

<sup>1</sup> See page 235 of the Journal.

<sup>2</sup> See page 229 of the Journal.

clusive as to this point. In the summer of 1889, I finished the works for the disposal of sewage at the Insane Asylum at London, Canada, partly by irrigation, partly by intermittent filtration. I had, last week, a letter from Dr. Bucke, Superintendent of the Asylum, stating that never had it, for a single day, failed to operate perfectly, and that they considered the question of the disposal of sewage in their case, as settled for all time. To-day, I do not hesitate to announce myself a more than enthusiastic advocate for the disposal of sewage by application to the soil, in one form or another, in all cases where this is possible; but I also recognize the fact, which seems very clear, that the power is great of disposing of sewage by the action of minute organisms, and by the growth of plants in water, and by the fish which live on these organisms and plants. I have had occasion to observe this in two instances within the last four or five years, one at Pensacola and another at Stamford, Conn. In the case of the latter, the sewage of the whole town, and in the case of the former the sewage of about three thousand persons was delivered into bays which were without current, and the testimony up to date seems to be very clear that within the limits to which the power of the water has been tested, it has been fully capable of dealing with all that has been sent to it. At Stamford, the bay into which the sewage is discharged is a semicircular one with no stream of water flowing into it and no direct tidal current. In recommending this I said that the fish might be depended on to take charge of all the sewage of the town that would be sent to it. The reply was made that there were no fish there; that they were all in the harbor, to which the natural drainage of the town flowed. After the usual arguments and delays and discussions, the recommended plan was adopted, and I am now informed that the best fishing ground is not in the harbor, but in this bay. Examinations made there last year, after the sewage had been delivered in considerable quantities for more than two years, failed to find any evidence whatever of organic matter along the shore or on the bottom of the shallow bay into which the sewage discharges. I should not in either of these cases have resorted to a discharge into water if I could have found suitable land and could have convinced the authorities that they had better spend the extra money necessary to use it.

There are all sorts of difficulties presenting themselves in the solution of a question of this kind, and the financial one is a very difficult one. The engineer having the work in charge will find himself controlled by the desire of the tax payer to make the cost as little as possible, so that in certain cases it is often necessary, or at least advisable, I think, to adopt the course just described.

I am glad to say that the testimony of the world is turning, rather strongly, I think, in opposition to all methods of treating sewage chemically. I do not think this method is used in this country except in one or two cases in connection with hotels, and I see very little disposition to extend its use. On the contrary, I find it becoming easier, in cases where the lack of a means of disposal has stood in the way because a town had no water into which to deliver the sewage, to convince the people that their sewage can be disposed of on land. There are many places where it is impossible to find what would be suitable land, land that would take up even the quantity that a light loam would do,

in which case it becomes necessary to use four or five times as much land as would be required if the soil were heavier; but I believe there is no land capable of entilvation that may not be made available for the treatment of sewage by land.

I cannot resist the temptation to say that wherever the character of the soil, or its cost, or where difficulty from any cause stands in the way of procuring a large quantity of land, or where the sewage has to be pumped, it is by all means best to avoid the combination with the sewage of rain water in any form, even roof and yard water, not only because it becomes necessary to provide more land, but because the land itself becomes saturated by the rain, and is least capable of taking up sewage when the most sewage is offered. I think it will be found economical to give up much of the work done on the combined system, and to confine the flow only to that which needs purification, leaving rain water to be disposed of in some other way.

DESMOND FITZGERALD, ESQ., of the Boston Water Department: I am afraid I cannot add anything to the value of the discussion as the treatment of sewage is not a specialty of mine. My time is devoted entirely to another branch of engineering, that of water supply, but in connection with the study of the water supply of Boston it has become necessary for me to make plans for sewage disposal, and I have tried to keep somewhat *au courant* with what has been going on in this science.

We have been troubled with sewage contamination in the brooks feeding our supply. To get rid of this pollution has been a hobby of mine for a number of years. About twelve years ago I first took up the subject, realizing that the longer time sewage is discharged into the brooks the more difficult it becomes to get rid of the evil. I am very glad to say that our efforts have been very largely successful, and that now a comparatively small amount finds its way into the brooks feeding the Cochituate and Sudbury River districts, still our efforts in this direction must be untiring for a long time to come. The town of South Framingham, which formerly discharged some of its sewage into our sources now has a system of sewage filtration to which we contribute liberally. It has been very successful. The field is entirely outside of our water supply, and the sewage is pumped over the divide and distributed to the beds. These beds have been prepared by taking off the loam and building low embankments around areas of two or three acres. The sewage is discharged directly onto the gravel. I have noticed that the matter left on the surface curls up and disappears. It is sometimes almost like a thin film of felt. The effluent, fifty feet from where the sewage is discharged is perfectly clear. We intend to see that this system is carried out for the other towns on our watershed.

The case of Marlborough is one of the most difficult I have seen. That town is situated in a very hilly region, composed almost entirely of unmodified drift, and it looked for some time as if we should be unable to find a good filtering area there. It illustrates how difficult it may be sometimes in an inland town to find a suitable area in the proper position. It seemed at one time as though we should be obliged to adopt the field selected by the State Drainage Commission, which was within our watershed, but this has been avoided. The works at Marlborough are now being constructed.

Westborough we are now working on and then there will remain Natick. By carrying out a vigorous policy we shall be able to get rid of almost all the immediate danger of the contamination of our water supply.

I have been for many years an ardent believer in the application of sewage to the soil. The first practical work of this kind, with which I was brought in contact was that by Colonel Waring for the State Prison at Sherborne. That prison was built directly inside our drainage area against my vigorous protest, and it was not long before the whole of their sewage was discharged into one of our brooks. It took a year or two of hard work to get an appropriation from the State to remedy this evil.

In concluding, Mr. President, permit me to add, that I believe the medical profession can and does materially aid engineers in carrying forward these beneficent sanitary works which are for the good of the people, and that I have seen several cases where the work of this Society was largely instrumental in instituting reform.

MR. ELIOT CLARKE: Dr. Barnes has summed up the truth about sewage-disposal, in saying that each case must be considered by itself, and that the method of treatment selected must depend upon the local conditions of the place. I am glad that he cited the very valuable report of the Royal Commission on Metropolitan Sewage Discharge, because that Commission obtained and sifted about all the trustworthy evidence to be had concerning sewage-disposal, and its conclusions may be relied upon as giving the exact facts and the state of the science at present. I believe Dr. Barnes did not quote its conclusion in regard to the profit to be expected from sewage-farming. In substance it was this: "In some very favorable cases a profit may be made without purification, and very frequently purification may be effected without profit, but, apparently, the two cannot be combined."

This agrees with what I found several years ago, when I visited most of the places mentioned by Dr. Barnes and also many others. None of the sewage-farms were profitable, and at all of them it was customary occasionally to turn the sewage directly into the streams, without applying it to the land, when the condition of the crops was such that they would have been decidedly injured by any further flooding with water. At Gennevilliers the sewage is only turned upon the land when it is wanted; during rainy seasons, when more water would hurt the crops, it is turned into the Seine. Applied thus, only as needed, sewage irrigation is very valuable, especially for an arid, sandy soil like that at Gennevilliers, which would be worthless for cultivation without irrigation.

In regard to the Boston Main Drainage System I should like to say that it has been working well for seven years, and precisely as was intended. The occasional overflow of very dilute sewage, at the old outlet, during rain-storms, was expected and does not cause any trouble. This would be avoided if we had at Boston a double system of street-sewers, one for sewage proper and the other for storm-water. Our system of final disposal is satisfactory. Practically it is the only one open to us, because there is no sufficient tract of land available, suitable for irrigation. If we applied the same quantity of sewage to an acre as is commonly used in England (as at Croyden, for instance), we should need a farm considerably larger than the whole town hip of Brookline.

DR. BARNES: In regard to Dr. Abbot's suggestion it is hardly fair to answer it in his absence, but my idea in reading the paper, and bringing the attention of the profession to the subject is that an earnest effort may be made to find the land. If the sewage can be completely purified by this process, and our garden farmers employ water at their own expense and do it profitably, it seems unreasonable that they could not utilize the sewage for the same object; and I do not think it would be a very difficult task to find in Arlington or Stoneham territory sufficient for local needs.

I cannot agree with Colonel Waring that sewage can be discharged continually into water without objection. The experience of the world is against it. I admit, for a limited time, living organisms in the water will undoubtedly take care of the sewage, but experience shows that these living organisms, the fish he mentions, are after a time driven away. I have noticed repeatedly in the Fen's basin where sewage has been discharged for three or four years. At first it made no impression on the fish, but in the last two years there have been periodic epidemics when decomposition seems to occur, and the shore is lined with dead eels and perch, and the pond would be very offensive for a few days, then it would clear itself and resume its normal condition. This, I believe to be caused by the accidental invasion of organisms promoting a putrefactive change, and the consequent exhaustion of oxygen in the water. If sewage is discharged into tide-water it must be precipitated and accumulate, and at low tide become offensive on exposure. I don't say it is necessarily dangerous to health. People can sometimes be exposed to bad odors without being made sick. I think that is shown in the Mystic water basin.

It seems to me the beauty of any water must be destroyed to say the least, and that is the objection which I have to our present method of gathering the sewage from a great metropolitan district and mixing it with the storm water of Boston, so that in times of storm it must be discharged along our water front. It would certainly mar the beauty of our water ways which we hope to have preserved. Whether it will make us sick or not must be determined. I think the intermittent discharge is less harmful than the continuous discharge, but how much you can discharge into water without offensive results I do not know. I think earnest efforts should be made, in all cases, to find land where we know it may be discharged without objectionable features.

Mr. Clarke speaks of no profit having accrued to any sewage-farm. Dr. Carpenter says the Croyden farm was for years a source of profit, until politicians controlled it. In the case of the Berlin farms one and a half to two and a half per cent. after deducting interest on cost of land in use is a little better than throwing it away. Some years ago a pamphlet was published by Peregrine Birch, giving fifty instances of profitable sewage-farms. This was published by a man pretty well known as an engineer.

PROFESSOR VON HELMHOLTZ. — It is proposed to celebrate the seventieth birthday of Professor von Helmholtz, which occurs on August 30, 1891, by presenting to him a marble bust, and striking a special medal to be bestowed upon eminent physicists.

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.<sup>1</sup>

## AN INQUIRY INTO OUR PRESENT KNOWLEDGE OF THE PROGRESS OF MYOMATOUS TUMORS.

THIS was the title of a paper by Dr. J. F. W. Ross, of Toronto. As a summary of a very elaborate survey of the whole subject covered by the title of the paper the speaker said that the fallacies which existed in respect to the treatment of this class of growths, were due first, to the slow development of the tumor, and the difficulty in appreciating the changes in size. Second, to the fact that when they reached a certain size many of them had no tendency to increase even if no treatment was given. Third, to the fact that after the climacteric period many of the growths remained inert or underwent retrogression, and also that many patients did not come for treatment until this period was approaching. The supposed effects of treatment continuing as it usually did over a long period of time, might only be coincident with the natural processes of cure. The speaker's idea of what such treatment should be, was as follows: If a patient was not near the menopause, was suffering in her health and was willing to submit to operation he advised the removal of her ovaries and tubes. If the diagnosis of the case was not clear, and a pelvic mass was found simulating a myoma, he urged operation. If the patient would not submit to salpingo-oophorectomy and had not an intra-uterine myoma that could be removed per vaginam, and was suffering from hemorrhage, the interior of the uterus should be treated with hemostatics. To this class of remedies belonged the actual canter and the positive electrode as well as the older remedies. If the tumor continued to grow, notwithstanding these procedures, and gave rise to uncontrollable hemorrhage, sloughing peritonitis and septic symptoms, causing dangerous pressure on pelvic or thoracic viscera, abdominal hysterectomy, myotomy or enucleation from below should be performed. If the patient refused to have this done galvano-puncture might be resorted to. It required very little irritation to produce alterations in the nutrition of these growths and cause suppuration or a retrogression. The speaker was a firm believer in the efficacy of galvano-puncture in many cases, but he did not believe that either it, or intra-uterine electrolysis would cure or relieve permanently anything like the number of cases accorded them by the supporters of these methods, or that these methods would be accompanied by the low death-rate claimed. After abdominal galvano-puncture and after many cases of vaginal galvano-puncture hysterectomy became an almost impossible operation owing to the presence of adhesions. Electricity was fast losing its fashionable favor, its clouds of mysticism had rolled away and we were now able to gain a more accurate view of its real value in the treatment of myomata. The battery was walking in the footsteps of the spray, and in the future, though not fulfilling all our expectations, might remain of use in a variety of ways.

Dr. GILL WYLIE said that electricity, except as a destructive agent to destroy the tissues of the tumors, was practically of no influence. If used to stop hemorrhage it must be in strength to act as a cautery. It was important to recognize the great objection of any form of treatment which would leave a scar in the

uterine tissues, and which would be liable to close up the glands and follicles, thus interfering with the normal secretion and setting up a train of reflex symptoms which might turn out to be worse than the disease for which the treatment was instituted. He considered the use of electricity as dangerous as that of operative procedure. If the tubes and ovaries could be removed completely, and the tumor was no larger than a child's head, success was almost sure to follow operation. Increased size and the presence of adhesions augmented the difficulties. Dr. Ross had advised dealing with intra-uterine tumors by electricity. He must oppose his view and state his conviction that if risk must be run it is better to incur those of hysterectomy.

Dr. CURRIER believed that there existed cases in which electricity could be employed as the most advantageous therapeutic agent at the time. He did not feel that it was going out of use with the spray. He thought that they were wrong to throw aside an agent whichever, even if only for a time, afforded relief, and there was no doubt this could be done in many cases by the application of the positive pole within the uterus.

## TREATMENT OF PELVIC INFLAMMATION IN WOMEN.

Dr. L. S. McMURTRY, of Louisville, read a paper on this subject. He thought pelvic cellulitis so rare a condition as to be practically excluded from a consideration of operation in women. Pelvic peritonitis, however, was of such common occurrence, so recurrent, and so dangerous in its sequelae, to comfort, health and life, that it was the most important of the affections encountered in gynecic practice. After reviewing the various forms of inflammation which might be relieved by such palliative measures as warm sitz baths, rest, hot douches, massage, counter irritation, saline purgatives and so on, he said that when a patient presented the history of recurrent attacks of pelvic inflammation, it was indicative of leaky tubes. The only treatment which would cure was removal of the diseased appendages by abdominal section. It was folly to wait for the advent of rupture and general peritonitis before making a decision. It was amazing to see with what reluctance the profession had come to accept this great advance in pelvic surgery. Even now when masses of suppurating tubes and ovaries were dug out of the pelvis in the midst of virulent peritonitis, and the patients were saved from a hitherto fatal condition, many eminent members of the profession stigmatized the procedure as castration of women. So far as he was aware surgeons operated upon the female pelvis for local disease only, and never with the idea of effecting a cure of reflex disturbances and obscure symptoms.

## THE TREATMENT OF INJURIES TO THE FLOOR OF THE VAGINA.

This was the title of a paper by Dr. H. T. HANES. He stated that no deep laceration could occur without destroying the integrity of those fibres of the levator ani which pass and meet above the rectum, and that when they gave way the transversus perinei encouraged a still further gaping of these lateral fibres. The obstetrician should try to avoid the accident, but when it did occur he ought to proceed to repair the injury within four hours. To do this he should place the patient on the edge of the bed, or on a table before a good light, choosing the lithotomy position. With the finger in the rectum so as to judge of the severity of the injury, a needle was then passed down to the right

<sup>1</sup> Eighty-fifth Annual Meeting, held at Albany, February 3-5, 1891. Concluded from page 215 of the Journal.

and left of the rectum, far enough to catch the fibres of the levator ani muscles.

Most of the modern methods of performing these repairs were not successful, as they were simply skin operations, which failed to include the muscle.

#### LOBAR PNEUMONIA WITH THE FORMATION OF NEW CONNECTIVE TISSUE,

by DR. FRANCIS DELAFIELD, of New York.

In describing this special form of lobar pneumonia, he said that the ordinary belief had been that it was possible for a regular exudative lobar pneumonia, instead of resolving, to be succeeded by a chronic productive inflammation. The speaker's belief, on the contrary, was that a regular exudative lobar pneumonia terminated only in resolution, or in death, and that lobar pneumonia, with the production of new connective tissue was, from the first, a special form of inflammation of the lung. His reason for this belief was that he had seen a number of lungs which seemed to show the different stages of the inflammatory process. He had twelve cases, the histories of which he used to demonstrate that there was a form of lobar pneumonia, which was, from the outset, anatomically distinct from the ordinary form. The development of the lesion seemed to be as follows: (1) Congestion of the lung; exudation of serum, fibrin and pus into some of the air spaces, the formation in other air spaces of irregular plugs with prolongations from one space into others. These plugs were composed of a nearly homogeneous or finely fibrillated material, none of them large enough to fill or distend the air spaces. There was also swelling and thickening of the walls of the air spaces with a very considerable increase of the number of air cells which covered them, and a more or less general catarrhal bronchitis with fibrin of the pulmonary pleura. (2) New cells of the type of connective tissue cells, were formed in the plugs, the walls of the air-spaces were more swollen and might be infiltrated with small round cells. New blood-vessels were formed in the plugs, which could be artificially injected from the pulmonary vessels. The gross appearance of the lung at this time was usually characteristic. One or more lobes were consolidated, they were not large as in ordinary pneumonia, but their color was red or green, and the cut surface smooth, not granular. (3) The growth of new connective tissue within the air-spaces in their walls, and along the arteries and bronchi was so extensive that many of the air-spaces were obliterated. The surface of the lung was not covered with connective tissue adhesions. The bronchi contained mucopus. The lung was red, mottled with white, gray or black, and was dense and hard. Portions of it might be necrotic, cheesy or broken down into cavities. The clinical symptoms of this type differed somewhat from the ordinary form of lobar pneumonia. Although the patient had the same chill, fever, cough, expectoration and pain as in the regular cases, yet there was something about the course of the disease which made its diagnosis possible even during its early stage. The temperature did not run high, but the tendency to cerebral symptoms, and the typhoid state was very marked, and most of the cases ran a protracted and subacute course. As to the prognosis, there seemed no reason why recovery should not be possible.

#### ON THE ETIOLOGY AND PATHOLOGY OF PHTHISIS.

DR. HENRY C. GIBBS, of Ann Arbor, said that,

on examination of the lungs of people who had died from disease of these organs, varied appearances were presented to the naked eye. These ranged from the small nodules found in acute miliary tuberculosis, to the large ragged cavities found in those cases where the disease had even a more chronic course. There was one feature, however, which was common to all, and that was consolidation. This disease he considered, if judged by the lesions found in the lungs, to be of two kinds, one inflammatory and the other a new growth of reticular tubercle. The first, the inflammatory, consisted of pneumonic phthisis and the inflammatory form of acute miliary tuberculosis. The second, the tubercular, consisted of pulmonary tuberculosis and the tubercular form of acute miliary tuberculosis. Pneumonic phthisis, whether commencing as broncho-pneumonia, or starting *de novo* in the lung substance seemed to him to be as easy of explanation as any other inflammatory process. The inflammatory form of acute miliary tuberculosis was also easily explained, as it was well-known that it often occurred in measles as did capillary bronchitis. In a child with deficient expectoration, inflammatory products would accumulate in the bronchioles, a sudden fit of coughing would cause these products to be drawn into the lungs in inspiration, they would then be distributed into a number of air cells, and their presence would be sufficient to cause inflammatory action even if they contained no morbid product. This would go on until there were a number of foci throughout the lungs which would not be all of the same age, and this was exactly what the microscope revealed. But when we tried to explain the relationship of tubercle bacilli to these two forms of inflammatory diseases, the disease must be found in its earliest stage, and this we could not do in pulmonary phthisis as the process had usually gone too far when death took place. We could, however, in the inflammatory form of acute miliary tuberculosis find the process at its very first development, careful examination in a large number of cases had failed to show tubercle bacilli in this situation, and yet when the process had gone on to caseation, they were invariably present in enormous numbers. In pulmonary phthisis they were also present in large numbers, and in those cases of rapid breaking-down, called galloping consumption, they were also present and were noticeable from their size and the number of so-called spores they contained. In acute miliary tuberculosis when the bacilli were found they were not in the necrosed portion as might be expected, but were found singly in the meshes of the fibroid tissue, they might in this case be considered as forerunners of the disease, but if they were, they ought also to be found in those tubercles where the disease process was just commencing, but in these locations the speaker had never found them.

#### THE THERAPEUTICS OF PULMONARY PHTHISIS.

DR. E. L. SHURLEY, before taking up his subject, stated that he coincided with Dr. Gibbs and others in entertaining a doubt as to the entity of so-called tuberculosis and phthisis pulmonalis, and also as to their specific origin uniformly in the operation of the bacillus tuberculosis. Although the nature of this microbe had been so plainly and definitely unfolded to us by Koch, yet it seemed impossible both from a pathological and clinical stand-point, that such diverse conditions of the body, as general or miliary tubercu-

losis, the several varieties of phthisis pulmonalis, so-called tubercular peritonitis, so-called tubercular bone or joint disease, lupus, leprosy, chronic adenitis, so-called tubercular kidney could arise from either the incursion, development or latency of a single species of bacterium. Such conclusions were moreover not wholly based upon a philosophical comparison of clinical phenomena, but also substantiated by at least the following facts: First, that the bacillus was absent oftener than present in acute miliary tuberculosis, acute phthisis pulmonalis, or disseminated catarrhal pneumonia, tubercular peritonitis, tubercular disease of the joint and bone and so-called tubercular kidney. Second, that sputum dried in the sun, thereby having its bacilli destroyed, was capable of producing phthisis pulmonalis. Hence it would seem proper to believe that some other action of a bio-chemical nature resulting in the production of a ptomaine, leucomaine, toxine or toxalbumin, perhaps bearing some physico-chemical relation to the bacillus, might be accepted as the real disease process.

Turning to therapeutics, he included under the head of general treatment, nutrients, analectics, gavage, beverages, inoculation, vaccination, hypodermic injection, internal antiseptic medication, enemata, both medicinal and nutritive. Under the head of local treatment, came medicinal inhalations of gas, spray and powders, external medication, including counter irritation, cauterization, surgical measures, respiratory gymnastics, and pneumatic differentiation. The first and principal step in treating this class of diseases, was that of absolute rest aided by the judicious use of antipyretics and nutritives.

Whether anything could be accomplished by hypodermic injections was still a matter of conjecture. Thus far there was some promise from the use of subcutaneous injections of quinine, bi-sulphate and liquor potassæ. Among the antiseptics used in internal medication, were creosote, iodine, iodoform, carbolic acid, creoline, mercuric bi-chloride and biniodide, turpentine, resorcin and cupric phosphate. At the present time creosote and iodoform probably enjoyed the leading reputation. Among the medicinal inhalations, were carbonic acid, sulphurous acid, benzoate of soda, hydrofluoric acid, and peroxide of hydrogen and ozone. The latter two had been known to produce excellent results. Inhalations of carbolic iodine, menthol and creosote naphthaline and creoline had a decided beneficial effect on the so-called catarrhal states. Under inoculations, hypodermic injections, and vaccinations some very interesting experiences were related. The inoculation of animals with virus which had been taken after having passed through other animals, or obtained from animals which were affected with tuberculosis, or from the blood of tubercular animals proved negative as prophylactics. In guinea-pigs and monkeys it was found that if an injection of a grain twice a day of iodine, and up to a half a grain of chloride of gold and sodium was given for from three to six days before inoculation, and continued for two weeks after, that the animal was rendered immune from tubercular infection. Moreover, if monkeys were thoroughly treated hypodermically by these solutions, especially in alternation, they seemed to be incapable of acquiring phthisis pulmonalis by the insinuation of dried sputum.

These substances had also been used upon human beings with encouraging results. The result in gen-

eral tuberculosis had not been at all equal to that in phthisis. The general mode of administration was to give, first the iodine, beginning with a twenty-fourth or twelfth of a grain, increasing each day to one-sixth, one-half or even a grain, according to the constitution of the patient. When the symptoms of iodism supervened, a solution of chloride gold and sodium was used, beginning with one-twentieth of a grain, and gradually increasing to one-fifth or one-third. For the success of the plan it was absolutely necessary that the chemicals should be pure. The solutions consisted of chemically pure iodine, with iodide of potassium, pure water and glycerine. The gold solution was composed of chloride of gold and sodium, one grain to the drachm of pure glycerine and water.

#### KOCH'S REMEDY.

DR. A. JACOB, DR. H. N. HEINEMAN, DR. W. C. BAILY and others, in whom had been vested the work of making or superintending the most important of the initial experiments with Koch's remedy in this country, presented elaborately compiled reports embracing the most minute clinical observation of the cases so treated.

DR. JACOB considered that this new element in therapeutics was only the first instalment of a series of remedies of the same character. Though perhaps somewhat disappointed in the results thus far there was reason to hope that internal medicine would, by the aid of laboratory research, soon make equally as rapid strides as surgery had done during the last ten years. To the many who would soon have the opportunity of using the remedy he would suggest the employment of small doses used continuously. He had noticed that where he had induced considerable reaction and high fever, the cases did not do very well, while those which did not respond so actively had seemed to do better in the long run.

DR. G. H. FOX said that when he had first seen the effects upon lupus, he had felt inclined to anticipate similar results in eczema, but after repeated trials had been disappointed. He could not say that in his hands the remedy had proved curative in pronounced cases of lupus. Although improvement had undoubtedly resulted up to a certain point, there would then be a cessation of the curative process, and the cases would remain at a standstill. In only one instance had a cure resulted of lupus under his care, and in this the patient was nearly well before the injections were commenced. So far, the beneficial results were not what he had been led to hope for.

DR. F. BACON then gave in detail all the points in the first three cases in which the remedy had been administered in this country under his observation at New Haven, two being cases of advanced tuberculosis and one of lupus.

#### THE TREATMENT OF GALL-STONES.

DR. W. W. SEYMOUR, after reviewing the theories as to the possibility of dislodging, dissolving, or otherwise effecting a cure for gall-stones by medicinal agents, concluded with the emphatic opinion that these accretions could not be dissolved and that all medical treatment for their dislodgment was likely to prove valueless. He held that operation should be early resorted to in a well-defined case, and an exploratory incision should be made where doubt existed. The mortality, where the operation was undertaken before complications had arisen, was but small.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, MARCH 5, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

THE ILLINOIS STATE BOARD OF HEALTH  
AND MEDICAL EDUCATION.

THE Illinois State Board of Health has just issued another report on Medical Education of wider scope than any of its previous reports, as this year it treats of the medical schools of the whole world, and not alone of those of the United States and Canada.

These publications of the Illinois Board are an important factor in the gradual improvement which is taking place in the medical colleges. The publicity given to the bogus schools and those of low grade of requirements is certainly the best method possible to ensure a diminution of the evil, which up to the present time seems inseparable from the lack of supervision of our medical educational establishments. The present report shows a marked improvement in several respects, on paper at least, and there is reason to believe that a fair proportion of the apparent improvement is real.

Some of the statistics from the present report are of great interest. There are now 148 medical colleges of all kinds in the United States and Canada, there being 135 in this country and thirteen in Canada, and of these, 129 require certain educational qualifications for matriculation. In 1882, such preliminary knowledge was required by only 22 colleges. The number of colleges that to-day require attendance on three or more courses of lectures is 85, as compared with 22 that made such requirements in 1882. During the term from 1882 to 1891, the average duration of the lecture term has increased from an average of 23.5 weeks to 26.5 weeks. In 1882-83 there were eight colleges that held terms of but 16 weeks. The number that give such limited instruction at the present time is not given, but the number of colleges whose term is six months or more is 111.

An interesting comment on the necessity of educational requirements is given in a foot note of the report which read to the effect that two graduates are studying the three R's on probation for a license to practice in Illinois. The licensing of physicians by the

several boards of Alabama, Minnesota, New Jersey, North Carolina, South Carolina and Virginia as provided by law gives an opportunity for statistics of no small value. Of 1,183 graduates from various medical colleges of the United States, who were examined by these several boards, over twenty-four per cent. were rejected. This percentage is not as large as that of rejected candidates by the Prussian Commissioners, but the tests applied in this country are not as severe as those of Germany.

The Illinois Board consider it a matter of importance that the work of these examining boards should be as uniform as possible in order to bring about the best results so far as medical education and the regulation of the practice of medicine is concerned, and they desire that there should be a meeting of the examining boards of the different States and some system adopted by which examination papers may be exchanged.

There is general increase in the requirements for matriculation and the length of study required for graduation. The American Medical College Association was formed in May last, and adopted certain rules which do not reach the standard of our highest schools, but which are far above the average grade of a few years ago. How large a number of schools are included in the Association is not stated in the report, but even if some of the schools that most need to raise their standard of scholarship fail to make the advance, the agitation of the subject will eventually compel a change on their part. The first rule governing the admission of colleges to membership in the Association is as follows: "That the colleges shall require a graded course of instruction covering a period of not less than three courses of lectures of six months' duration each before graduation." It is not very surprising that certain medical colleges should have thought it unnecessary to subscribe to so low a standard, and it is to be hoped that all look upon it simply as a step towards better things.

The American Institute of Homeopathy has adopted a somewhat singular regulation. It specifies that after the autumn of 1892 the term of study required for graduation shall be at least four years, which shall include attendance upon not less than three terms of six months each. The second clause is to the effect that: "No person, unless he present a diploma or certificate of graduation from an accredited university, college, academy or high school, or a teacher's certificate, which shall be approved by the faculty as equivalent to the examinations required, shall be admitted to the second year of study, and the first course of lectures in any of the colleges represented in this committee without having passed a written examination" upon a series of subjects which are enumerated. It would seem as if every graduate of every accredited high school had completed the first year of medical study.

The subjects enumerated for the equivalent examination are: (1) English Composition; (2) Arithmetic; (3) Geography; (4) History; (5) Latin; (6) Phy-

sics, such as is comprised in Balfour Stewart's "Primer of Physics"; (7) Biology and Physiology, as much as is comprised in the briefer course of Martin's "Human Body"; (8) Chemistry, as comprised in Miller's "Elementary Chemistry"; (9) Botany, as found in an elementary manual.

"It shall be understood that the first of these four years of study shall have been devoted to the preliminary medical studies as outlined by this committee, and that upon successfully passing the above examination, the student shall have fulfilled the requirements of the first year of medical study."

It seems a little unfortunate to speak of such an arrangement as a four-years' term of study when it is in reality but the requirement of a certain amount of preliminary knowledge before matriculation. It might with equal justice be called a five or even a ten years' term of study. But in taking exception to the terms employed it must be said that if the entrance conditions are fully carried out there ought to be a fairly good result.

On the subject of preliminary education the report is in error in saying that Harvard University has made arrangements by which the students intending to study medicine can take a special A.B. course in three years. Such a modification of the four years' collegiate course, in order to prolong the time spent in professional schools, has been widely discussed by those interested, and strongly advocated by certain of the medical instructors, but has not been officially sanctioned.

It has long been recognized that the United States furnished an asylum for medical students who were unable to pass the State examination in their native countries. The Illinois Board seem to us to have done a service to the country by a regulation just issued to the following effect:—

"The Board of Health has decided that hereafter it will recognize no foreign diploma that does not confer the right to practice medicine in the country in which it was granted. The holder of an Austrian, a German, Russian or Swiss diploma, wishing to practice in Illinois, must hereafter pass an examination before the State Board, unless he has passed the State-Examination of the country from which he comes. The holder of a Canadian diploma, unless a licentiate of the Colleges of Physicians and Surgeons of Ontario and Quebec, must pass an examination before the Illinois Board in order to practice in Illinois."

#### THE CONTAGIOUSNESS OF SCARLET FEVER, DIPHTHERIA, AND SOME OTHER COMMON DISEASES.

In relation to measles, mumps and whooping-cough, it may be said that their contagiousness disappears with recovery. Moreover, during the period of incubation (which with reference to measles and pertussis may be estimated as about a week) there is probably no danger of contagion. It is the period of invasion and of activity that is eminently contagious.

In measles, the desquamative period is but little marked, and the fine scales which, during convalescence appear, are but slightly contagious when first shed, and speedily lose completely their contagious property. According to Cadet de Gassicourt, the contagiousness of measles does not positively extend beyond a fortnight.

Roger, who has made a careful study of the contagiousness of whooping-cough, affirms that at the end of six weeks the disease ceases to be contagious. The paroxysms of coughing may continue long after the contagion has ceased to exist. Cadet de Gassicourt, however, who believes that when the fits of coughing are no longer followed by glairy mucous expectoration, the contagiousness is no longer to be feared, yet thinks that it is prudent to prolong the isolation of the patient till the pertussoid paroxysms are over.

In scarlet fever and diphtheria, there is nothing to fear during the period of incubation; the pathogenic microbes have indeed infected the organism, but they are yet undeveloped, and have not elaborated their poisonous secretions.

In scarlet fever, the periods of invasion, of activity and of decline present nothing peculiar; it is the period of desquamation which is of most interest from a prophylactic point of view. Desquamation begins very soon after disappearance of the fever, and it is then that the contagion is most to be dreaded. The scales contain the virus, and the disease may be communicated by contact or by transportation to a distance.

Cadet de Gassicourt, from whose recent article in the *Médecine Moderne* we have borrowed, gives several illustrations of the contagiousness of these products of desquamation, and the persistent duration of the vitality of the virus:

A child, sick of scarlet fever, had occupied a certain apartment; after recovery, the room was properly disinfected, as was supposed; two months afterward, a younger brother spent a day in the apartment, and in less than a week came down with scarlet fever.

A lady living on the border of the Rhine was recovering from scarlet fever. She wrote a letter, and while writing it had to complain of the "dust" which peeled from her hands, and which obliged her continually to blow on the paper to clear it of these scaly products. The letter was sent to a friend in Brittany who opened and read it in the presence of her daughter. Both contracted scarlet fever; the little girl died.

A young boy was treated in Paris for scarlatina. Three months afterward he joined his brothers and sisters at Castres. One day while out for a walk, one of the sisters complained of feeling cold; the governess pulled a scarf from her pocket and put it around the child's neck. This scarf had unfortunately been worn by the little boy all through his sickness, and had not been disinfected; the sister came down with scarlet fever in the course of a week after the exposure.

Dr. J. Brooke, United States Surgeon, Fort Monroe, communicates the following case (*Medical Record*, August 4, 1888):

"A girl aged eight, living in this place, was attacked by scarlet fever, the disease running a typical course. For a long time no possible source of contagion could be found. The child had not been absent from home, had been with no one lately exposed, and no other case was known to exist anywhere in the vicinity. Subsequently I learned that one of the house servants had nursed a case of scarlet fever in a distant city just about a year before. After the case terminated, she packed some of her things, including some clothing then worn, in a trunk, and left the place. A year later she had the trunk sent to her here, opened it and took out the contents, the little girl being present and handling the things. Very soon after, the latter was attacked, as stated."

Dr. Hildenbrand treated a certain number of patients for scarlet fever. At the moment of leaving the city to go to his home in the country, he put into his carpet-bag the coat which he had worn while attending his scarlet fever patients, and it remained there more than eighteen months. One day, in a new locality, he unfortunately put on the old coat which had not been made aseptic since his visits to his former scarlet fever patients and in that coat made several sick-calls. Several days afterward a little epidemic of scarlet fever broke out in that neighborhood.

In diphtheria, the substratum of the contagion is solid; the virus resides in the false membranes either fresh or dried. If the liquids of the mouth are vehicles of the poison, this is said to be through fragments of false membrane which they contain. The pseudo-membranes are thicker and heavier than the scales of scarlet fever. Their dissemination to a distance is the more difficult, but they long preserve their contagious property. Cadet gives examples:

A rich citizen of Paris had in his private rooms at his hotel a child sick with diphtheria. The child recovered and went into the country, rejoining his brothers and sisters. During the entire summer the children were well. In the winter they went back to their hotel in Paris. Immediately two of the children contracted diphtheria. These recovered and again all went into the country. The following year they returned to their rooms in the hotel, diphtheria again broke out, and one of the children succumbed to croup.

A boy, five years old, died of diphtheria, and the room in which he died was left just as it was at the time of death, without any change of furniture, tapestry or hangings, by the folly of the mother, who wished thus to keep fresh the memory of her child. More than two years afterward, the second child, aged four years, obtained permission to sleep in the room where his brother died, and within three weeks contracted a fatal diphtheria.

Darolles gives another account, which he entitles: "History of a Cradle." In the course of an epidemic, an infant died of diphtheria in a wicker cradle, in the

country. Darolles urged the parents to destroy the cradle. They refused. Eighteen months afterward, another infant contracted diphtheria in the same place at a time when the disease was unknown in the village, and died. Again the physician urged the parents to destroy the cradle, and again they refused. Two years afterward a third infant contracted diphtheria in the same cradle and got well. A year later the same infant was again taken with diphtheria and recovered. Then the parents consented to destroy the cradle, and there were no more cases of diphtheria in that family.

#### ANNUAL REPORT OF THE MARINE-HOSPITAL SERVICE.

THE annual report of the Supervising Surgeon-General of the Marine-Hospital Service of the United States for the fiscal year 1890, is a somewhat bulky volume embracing a very wide array of subjects.

The *grippe* necessarily furnishes an important item, but not one of marked interest. The report from the Hygienic Laboratory consists largely of certain correspondence and an account of experiments on cobra virus studied in reference to its value as an antidote for cholera. This venom was proposed as a germicide by Mr. Perroux, of Calcutta, who hoped it might prove valuable in cases of cholera. The cobra poison was forwarded by Mr. Perroux from Calcutta, and its action on animal life, and on the culture of various bacilli was studied by J. J. Kinyoun, Assistant Surgeon in the Marine Hospital Service. His conclusions are not favorable to the therapeutic value of cobra poison.

One of the most interesting portions, and perhaps one of the most widely useful articles in the whole series, is a report on foreign hospitals, as seen by the writer in connection with his attendance at the late International Medical Congress. The bureau has for many years been the recipient of requests from different municipalities for plans and designs and suggestions in reference to the erection and equipment of municipal hospitals. The Surgeon-General thought it would add to the efficiency of the bureau if he collected as many plans of the foreign hospitals as was practicable, and made as thorough an inspection of the hospitals themselves, in the various cities visited as time permitted. Many ground plans and several interior and exterior views are given of hospitals in various cities of Europe. Those published are (by inference) only a portion of those collected. Such a collection ought to be a valuable one for reference; but it is impossible to give sufficient detail as a mere item in an annual report of a national medical service, to be of great practical value to municipalities seeking information.

One part of the report contains some interesting statistics in regard to immigration, showing the very large number of immigrants coming to the United States during the years from 1875 to 1890. This number of individuals enters this country without any

medical inspection whatever, except at the port of New York. This statement does not refer to the cases of leprosy, small-pox, yellow fever, or cholera, which are specially looked for at quarantine. Dr. Hamilton urges the propriety of such a supervision as shall ensure the exclusion of immigrants who are suffering from such contagious or chronic disease or disability as will make them a public charge.

The custom of printing many of the clinical reports and reports of autopsies is continued, doubtless to the great advantage of the service.

#### MEDICAL NOTES.

**VIRCHOW'S OPINION OF KOCH'S METHOD.**—At a meeting of the Berlin Medical Society on February 11th, Professor Virchow spoke at length on the effects of Koch's remedy, and concluded as follows: So far, then, there is no evidence that the bacilli are killed and dissolved; no direct facts to prove that the remedy causes resolution of the true tubercular tissue or the absorption of tubercle as such. We have a whole series of observations showing that the tubercle, as well as the inflammatory tissue surrounding it, is speedily destroyed, and that this destruction favors the possibility of a comparatively rapid healing process. On the other hand, we have no experience to prove that indurative processes are favorably influenced, or that encapsulation, the enveloping of caseous parts with fibrous masses, is favored. Rather, I feel bound to say, the suspicion sometimes arises that the remedy mobilizes encapsuled masses, brings them into movement, and thus transforms a focus, which might possibly have continued to be harmless, into an actual danger for the patient. Professor Virchow expressed the hope that the facts he had adduced might lead to more definite ideas as to the indications for the remedy, and the rejection of such cases as were manifestly unsuitable. He was far from considering these experiments as closed.

#### NEW ENGLAND.

**LEGISLATIVE HEARINGS.**—Before the Committee on Public Health of the Massachusetts Legislature during the week the continued hearing was held on the order relative to conferring the power to enforce sanitary provisions in public buildings and school-houses upon boards of health. Members of the State Board of Education and Superintendents of Schools appeared as remonstrants to the change. Hearing relating to the licensing by City Councils instead of Boards of Aldermen, of offensive trades: The protection of the community and that of cities and towns require more stringent laws in regard to controlling the methods in use in slaughter-houses. The business of slaughtering establishments has outgrown the provisions of the law as it now exists. Continued hearing in regard to ventilation of public buildings and schools: the present laws as now enforced are vigorously opposed by school committees in the smaller towns.

**A NOVEL REASON FOR STATE AID.**—A bill has recently been introduced in the Massachusetts House of Representatives appropriating \$300 to the man whose case is reported by Dr. Palmer on page 234 of this issue of the JOURNAL, as he was at work on the State camp-ground when struck by lightning. It seems that the State considers itself responsible for the accident.

**SUIT FOR NON-APPEARANCE.**—The daily papers have lately reported a trial in Connecticut, where the father of a boy, who had had his lip bitten by a dog, sued a physician whom he had summoned for refusing to attend the case, on the ground of a previous engagement. The claim was that by reason of non-appearance the boy suffered unnecessarily, and that the delay of medical attendance caused much more of a disfiguring scar than if prompt service had been rendered. The plaintiff won the suit, but only to the amount of ten dollars.

#### NEW YORK.

**INQUEST IN A CASE OF SUPPOSED OPIUM POISONING.**—A somewhat mysterious case of death occurred about the first of February, the mystery concerning which has not been very satisfactorily cleared up by the coroner's inquest, which was held February 27th. A pupil from New Jersey in a well-known young ladies' boarding school was found to be suffering from symptoms of opium poisoning, and, in spite of the most active and persevering efforts of a number of physicians, died. It transpired at the time that she had complained of frequent headaches and also of sleeplessness at night to a friend of hers, who is a medical student, and that he, believing her to be suffering from malaria, had given her a prescription calling for twenty-five grains of quinine and one grain of morphia, to be made up into six capsules, of which she was to take one on retiring. This he signed as a medical student and sent to one of the most reliable druggists in the city, where it was compounded. At the inquest he testified that when the capsules came, in order to avoid all possible danger from the morphia in them, he allowed her to have only four of them; retaining the other two in his own possession. These two he gave to the coroner, and an analysis by an expert chemist showed one of these to contain four and a half grains of quinine and a little less than one-sixth of a grain of morphia; thus showing that the prescription was properly put up by the druggist. The young lady was known to have taken one of the capsules; but whether she had taken any more or not could not be ascertained. The coroner's jury, which was composed of physicians and druggists, and the foreman of which was Dr. George L. Peabody, Professor of Materia Medica and Therapeutics in the College of Physicians and Surgeons, rendered a verdict to the effect that the deceased came to her death from opium poisoning, but that the amount of morphia alleged to have been in her possession (in the capsules), was not sufficient to cause death. The latter part of the verdict is explained by the fact that the jury was of the opinion that she

had more morphia in her possession than was shown by the testimony, but under what circumstances it was taken there was no evidence to show.

UNIVERSITY OF THE CITY OF NEW YORK. — An effort is being made to raise \$500,000 for the purpose of increasing the work and usefulness of the University of the City of New York, and among the changes proposed is the removal of the Academic Department from its present location on Washington Square to some desirable site in the upper district of the city. At a conference of friends of the University held February 26th for the purpose of talking over the needs and prospects of the institution, Professor Alfred L. Loomis remarked that the Medical Department of the University on its present basis had reached its utmost possible limit of success. "This year," he said, "there is a matriculating class of 694. Every professorship is filled with earnest and competent men, who receive salaries sufficient to compensate them. Without an endowment it would not do to raise the standard of the department, because to raise the standard to what it really should be would cause a falling off to about thirty per cent. of the students; while now the medical school is dependent for its maintenance on the tuition fees of the students." Dr. Loomis then went on to say: "At least \$500,000 that has been spent for hospitals in this city ought to have been given for educational purposes. New York has more hospitals to-day than the needs of the sick and indigent demand. Nearly one-third of the patients in our hospitals are pay patients who are able to be taken care of elsewhere. Rich New Yorkers are pouring out their money for hospitals and are allowing educational interests to suffer."

MALTEMENT IN A HOSPITAL. — One of the male nurses in Bellevue Hospital has been sentenced to two years and eight months' hard labor at Sing Sing prison for maltreating a delirium-tremens patient in the hospital. He was convicted of assault in the second degree.

DR. WILLIAM HENRY STEVENS, aged thirty-three years, assistant pathologist at the New York Hospital, died February 22d, at his residence in Brooklyn, of peripheral neuritis, resulting from an injury to his left forefinger received while dissecting last December. On January 23d, while the sore on the finger still remained unhealed, he made, in conjunction with another physician, an autopsy on the body of a patient who died of hydrophobia at the Chambers Street Branch of the New York Hospital, and in order to avoid, as far as possible, the risk of contracting the disease, he underwent a series of inoculations at the hands of Dr. Paul Giber, of the Pasteur Institute. This inoculation treatment was completed February 9th, and soon afterward the most serious symptoms developed. Dr. Stevens was a young man of great promise, and his untimely death is deeply regretted. He graduated from Williams College in 1879, and later from the College of Physicians and Surgeons of New York.

For six years he practised his profession at Cheyenne, Wyoming, and it is only recently that he returned to the East.

## Miscellany.

### SHARON SANITARIUM.

A SANITARIUM for the treatment of cases of incipient pulmonary troubles has been opened in Sharon, Mass., a town about eighteen miles southeast of Boston on the Providence division of the Old Colony Railroad, between 300 and 400 feet above the level of the sea, possessing a porous gravelly soil and numerous pine woods. The building can accommodate nine patients and is intended at first for women only, but it is proposed later to have small cottages adjoining for both sexes. Each patient has her own separate bedroom with an open fire-place as a means of ventilation. About ninety acres of land adjoin the building. Only cases in which signs of pulmonary disease are just appearing will be received, no hopeless or far advanced cases can be admitted.

This institution has been established by donations of many persons interested in the work, and is intended to reach a class of patients who, are unable to go to a distant climate, or to obtain necessary care and treatment at their homes. The expenses of the Sanitarium will far exceed the income from patients, and the management will have to depend upon the annual subscriptions, donations and bequests of people interested.

The institution is under the medical direction of Dr. Vincent Y. Bowditch, assisted by Dr. Robert W. Lovett, and a Consulting Staff: Drs. Henry I. Bowditch and Frederick I. Knight.

All applications for admission should be addressed to the Matron and Superintendent, Miss Sylvia C. Coffin, Sharon Sanitarium, Sharon, Mass.

### METHYL VIOLET IN THE TREATMENT OF MALIGNANT GROWTHS.

At a meeting of the Vienna Imperial Royal Society of Physicians on January 30th, Professor von Mosetig<sup>1</sup> reported some remarkable results which he had obtained by parenchymatous injections of methyl violet (pyocetanin) in cases of malignant growth. Starting from the idea that if the nuclei of the cells of the neoplasm could be destroyed its development could be checked, and bearing in mind the affinity which the nuclei exhibit for aniline dyes, he tried, as far back as 1883, the effect of injecting trichlorate of aniline in four cases, but it had to be abandoned on account of the disagreeable secondary effects. When pyocetanin was introduced, he at once proceeded to try it in malignant growths.

At the meeting referred to he was able to show several cases in which the results had been most satisfactory. Among these was a woman aged sixty-six, with a large tumor of the lower jaw which prevented her from swallowing, and caused great suffering from constant salivation, etc. After thirty-five injections of six grammes of a 1 in 500, and afterwards 1 in 300, solution of methyl violet, the tumor was so much reduced without ulceration, that the patient could eat with comfort. In a man, aged fifty-eight, with a cystosarcoma of the

<sup>1</sup> British Medical Journal, February 7, 1891.

chest-wall measuring thirteen centimetres in width by eight in length, after twelve injections of six grammes of a 1 in 300 solution of pyocyanin, the measurements of the tumor were reduced to ten by six centimetres. In two cases of adenocarcinoma of the neck, the same treatment proved so effectual that the patients considered themselves cured. Another case was that of a woman, aged sixty, with papilloma of the bladder. He injected twenty grammes of a 1 in 1,000 solution into the bladder, repeating this every two days. After ten injections there was notable improvement, the hamaturia had ceased, and there was little or no pain.

## Correspondence.

### SHALL TUBERCULIN BE PROMISCUOUSLY USED?

Boston, March 2, 1891.

MR. EDITOR:—As many practising physicians may be tempted to use Koch's material, which is now on sale both here and in New York, I should like to call their attention to a few facts upon the subject. As a means of diagnosis the material is acknowledged to have but little or no value. In about one half of all cases used as "control experiments" a local or general reaction has followed. While in many cases, clearly tuberculous, there has been no appreciable reaction. Professor Leyden<sup>1</sup> states that the classic reaction does not give positive proof, and as the effect upon the physical condition may be painful, no patient should be subjected to the treatment for diagnostic purposes. Professor Schreatter<sup>2</sup> has said: "The diagnostic value of the material has already been settled by present investigations. The result is unfortunately a negative one."

To turn now to the therapeutic value of the material. As Dr. Henry Jackson stated in the last issue of the JOURNAL, no single case of absolute cure has been recorded of any tuberculous lesion. No cure of lupus that would stand the criticism of the dermatologists is on record. V. Bergmann<sup>3</sup> states that no single case of bone or joint tuberculosis under his observation has improved. At the Great Ormond Street Hospital for Children, after a two-months' trial, the use of the paratubercin has been discontinued, because there were no positive results. Virchow's autopsies, deaths from small doses<sup>4</sup> (two milligrammes), development of tubercular meningitis<sup>5</sup> after a very short course of treatment (though this is not necessarily a *propter hoc* case), and many lesser unpleasant results in the wards, all go to prove that the material may be very dangerous. Consideration of all this leads V. Schreatter to say that no one can to-day advise with a clear conscience any patient to use the material.

Observation of about thirty cases during the last two months would bring my conclusions to coincide with the above. While most of the skin cases have shown improvement, the joint cases have given no sign of gain, and the phthisical cases have shown no improvement more than can be accounted for by a hygienic life, with plenty to eat and drink. Some cases have become worse during the treatment.

There is, of course, another side to this question. There are many reports of great and favorable improvement which cannot be fairly ascribed to anything besides the use of the paratubercin. As to the permanency of these results, time alone can decide. Meanwhile, those cases already begun upon should be most carefully followed under the most favorable circumstances. And I feel sure that the majority of men who have followed the cases at the various hospitals will agree with me that, for the present at least, and until much more careful experimental

work has been done, the Koch material should have no place among the general everyday therapeutic measures for the treatment of tuberculosis.

Respectfully yours,

A. K. STONE, M.D.

## HOME TREATMENT.

Dorchester, Mass., February 28, 1891.

MR. EDITOR:—The inclosed cutting (from the *Taunton Daily Gazette* for February 25, 1891) may be of interest. It may throw light on some "obscure" case of poisoning.

To get rid of a cold send to the druggist for a mixture containing sulphate of atropia one two-hundred-and-fortieth of a grain, bi-sulphate of quinine two grains, and Fowler's solution, five drops, to each dose. Take a dose once in two hours for three or four times, or until the throat begins to feel slightly dry. If this does not entirely relieve the symptoms, repeat the treatment the next day. Copy this prescription carefully, and use it with care, as some of the ingredients are poisonous. There is no danger in using it if the directions are followed exactly.

Before going to bed take a warm bath. The next morning sponge the body rapidly with tepid water, rubbing it hard until the blood circulates quickly and the skin is in a glow. Take more exercise than usual, and do not sit in a hot room with the windows shut. Mix a teaspoonful of cream of tartar in a tumblerful of water and drink it during the day. If there is constipation, take a gentle laxative, as a rhubarb pill. It is very important that all the avenues of the body for carrying off waste matter should be wide open.—*Ladies' Home Journal*.

By the way, in case of serious poisoning, from an honest attempt at home treatment on this advice, who would be responsible, if any one? Very sincerely yours,

CAUTION.

## RECORD OF MORTALITY

THE TREATMENT OF FIBROID TUMORS OF THE UTERUS AFTER THE METHOD OF DR. APOSTOLI.<sup>1</sup>

BY JOHN HOMANS, M.D., BOSTON.

EVERY one who has felt obliged to remove uterine tumors by laparotomy has often hesitated at the performance of the operation, and has hoped that some method would be found other than the formidable one which necessitates opening the abdomen and putting a wire around the uterus. Every surgeon dreads, at least I do, to make the long incision, sometimes more than twelve inches, to squeeze up the uterus in this coarse and cruel way. Besides this the resulting cicatrix is not unfrequently the seat of an annoying ventral hernia. When, therefore, Dr. Apostoli published and explained his treatment of fibroid tumors of the uterus by electrolysis, and gave the details of several hundreds of cases treated in this way, I hoped that a more gentle and perhaps as effectual a way of relieving those affected with these growths had been discovered.

For my own part I never have seen, and I do not see now, why the dispersing and dissolving powers of electricity should take effect on the fibroid growth and not on the skin or muscle or tendon or fat or other structure through which the current passes. When we apply one electrode within the uterus and the other on the abdomen, why should the destructive powers of the current be exerted and take effect (as we wish) on the morbid growth, and not on the normal tissues? The fibroid tumor is nothing but an aggregation of normal uterine tissue in an abnormal and excessive amount, and why should this aggregation of fibre be attacked and nothing else? I was slow to adopt Dr. Apostoli's treatment, and I knew nothing about the therapeutical effects of electricity. When, however, a friend, who is perhaps the most successful hysterectomist in the world, wrote me that he had tried electrolysis, and could endorse every word that Apostoli had written, it seemed to be my duty to subject my patients to this almost harmless method instead of compelling them to undergo a dangerous surgical operation. As I knew nothing about electricity or its application, I asked my friend Dr. Philip C. Knapp to provide me with a battery and with all the apparatus called for in Dr. Apostoli's treatise written by Dr. Lucien Carlet.

I began the treatment of such fibroid cases as came to me in my private practice in December, 1887, and continued to treat them till July, 1888, and resumed treatment again in October.

I wish to say that I have followed strictly Dr. Apostoli's directions to the best of my ability. As all of my readers may not be familiar with these directions, I will state my manner of proceeding. The patient, having her abdomen bare and lying upon a convenient table, is given an antiseptic vaginal douche; then a flat, somewhat pliable and perforated metal plate, about nine inches by five, is enveloped in warm, moist pottery's clay and wrapped up in muslin (like a poultice); this is then laid upon the abdomen in the pubic and umbilical regions over the tumor; after this the sound

of platinum (for silver might be melted by the current) or of gas-carbon, is introduced into the uterine canal. When this has been inserted as far as possible, a protective tube of hard rubber is shoved up against the os uteri, so that the vaginal wall shall nowhere come in contact with the bare platinum (for it might be severely burned). The wires of the battery are now connected with these two electrodes, that is, with the plate on the abdomen and the sound in the uterus, and the patient's hands are pressed down upon the clay. If the case is one in which there is great hemorrhage the uterine pole is made the positive one, as the positive pole is said to exert a chemical cauterization and to stop or diminish hemorrhage. If there is no hemorrhage, the uterine pole is made the negative one, because the negative one is said to have a dissolving or disintegrating or dispersing effect. A rheostat, or electricity measurer, is then connected so as to allow the current to pass, and the amount of electricity passing is measured by a galvanometer and is regulated by the rheostat. It is recorded in milliamperes, that is, in degrees marked on the dial of the galvanometer, each degree being an amount of electricity called a milliampere. (In recording these cases I shall use our usual mark for degrees as signifying milliamperes: thus, 42° will mean 42 milliamperes.) I hope I have not been too tedious in this description, and yet have made things clear. In these treatments I confined myself wholly to giving the antiseptic douches, to introducing and holding in position the uterine electrode, and Dr. Knapp turned on and regulated the amount of electricity as I directed. Later on, my nephew, Dr. John Homans, 2nd, took Dr. Knapp's place.

If this treatment by electrolysis is tolerably sure and safe we ought to practise it; if it is not so, it is a great waste of time and very tedious and useless. Again, the battery is cumbersome and expensive if trustworthy. I determined to settle the matter for myself if I could, because I thought it would be criminal to do hysterectomy if I could cure patients by Apostoli's method. I put one hundred and fifty Le Clanché cells in the cellar of my hospital, as the simplest and best battery.

Before giving very brief reports of the cases treated, let me say that one frequent but not invaluable good effect of this treatment is the diminution or cure of pain and tenderness and an increased ability to walk and stoop. A very marked anæsthetic and tonic effect is often also produced. One of the women, who was unable to go up stairs without resting every second step, was able after a few treatments to run up two flights, and others who were unable to bear any pressure on the abdomen could wear their clothes and move with ease and comfort; but these improvements were by no means always permanent. In one instance also, chronic menorrhagia was cured. So much for the good effects of this treatment. On the other hand, pain and discomfort is sometimes produced, and hemorrhage which has not before existed has become troublesome. One case terminated fatally four weeks after the last application of electricity; and, in the absence of an autopsy, I think the death must be attributed to septicæmia caused by the treatment.

I have sent the following circular to all the persons treated, most of whom have returned answers to the questions. These will be found (printed in small type) at the end of the description of each case.

<sup>1</sup> Read before the Boston Society for Medical Improvement, January 12, 1891.

NO. 164 BEACON STREET, BOSTON, MASS.

DEAR MADAM:

I am very anxious to learn how your health is at present, and whether you are better or worse than when I saw you. You may remember that you consulted me on . . .

Will you oblige me very much by answering the questions in the inclosed circular, and mailing the same to me in the accompanying envelope? Please add such other information as you may deem relevant.

Very respectfully yours,

JOHN HOMANS.

General state of health?

Increase in size of tumor?

Decrease in size of tumor?

Monthly sickness - regular?

Irregular?

Profuse? Scanty?

Painful?

Are you stronger? or weaker?

Has the fat over the stomach increased - that is, are you stouter?

Can you walk better? Can you stoop better?

Or is there no improvement in these respects?

Have you pain?

Any children born since consulting Dr. Homans?

Have you had any treatment since consulting Dr. Homans?

If so, what?

#### CASES OF ELECTROLYSIS TREATMENT.

CASE I. December 20, 1887. Mrs. P., forty-three years old. Has a hard fibroid tumor filling the abdomen to a point an inch above the umbilicus, and extending from one anterior spine of the ilium to the other. It does not fill the vagina, and the os is with difficulty reached under and behind the pubes. In 1876 she was confined with twins, and has had five abortions. She is fat and muscular, but anemic and white. The tumor is movable, somewhat tender. Umbilical girth forty-two inches. Catamenia excessive; and there is a slight hemorrhagic flow constantly from the uterus; at times there is flooding. A slight hæmic murmur is heard with the sounds of the heart. The tumor was discovered in June, 1886.

The interior of the uterus was curetted on October 10, 1887. The two succeeding monthly periods were slight in amount, the third, on November 22d, was very profuse, the excessive hemorrhage lasting thirty-six hours, with a loss, as she thought, of two quarts of blood, and leaving her very weak.

On December 20, 1887, galvano-caustique, positive, 50°, eleven minutes; sound in utero three inches; rest in bed all day. On December 22d, catamenia began painless, with slight flowing; galvano-caustique, positive, 50°, nine minutes. On December 25th, catamenia ceased, having lasted three days instead of eighteen, and instead of being terribly painful, were painless, and instead of being hemorrhagic were normal.

December 31st, a watery-looking discharge from the uterus took place. January 28th, catamenia again normal, but more painful. February 29th, again normal, but without pain. December 27th, and 31st, galvano-caustique, positive, 50° and 135°, three minutes; sound in utero.

This case was greatly improved in regard to pain and hemorrhage, but the growth of the tumor was not checked.

October 19, 1890. Health very good. Tumor a good deal increased in size. Menstruation at regular intervals, not very profuse, not painful, and not attended with any of the troubles mentioned. Tumor walks up and down. Has a son and two children born since consulting Dr. Homans. Treatment for two years, since consulting Dr. Homans, reported remedy.

CASE II. Mr. McK., house-keeper. Never pregnant. Consulted Dr. Homans many years since. Tumor very prominent, filling abdominal cavity to a point an inch above the umbilicus and two inches

below ensiform cartilage; fuller on the right side than on the left, rising to within three fingers' breadths of the cartilages of the right ribs; on the left side more tender and more prominent, anteriorly rising to within two finger's breadths of cartilages of ribs at sternal angle. The tumor extends from one anterior spine of the ilium to the other, and is somewhat irregular in shape. In 1881, or earlier, she noticed a bunch in the right lumbar region, and in December, 1882, tumors on both sides; on the left as high as the navel, and on the right not as high. In the winter of 1882-83 had severe peritonitis, and took much morphine. No menorrhagia till September, 1887. She has always had more or less pain constantly, particularly at night, but nothing like hemorrhage. There is now (December 1887), pain and tenderness all over the abdomen, necessitating the use of a cradle to keep off the pressure of the bed-clothes. In short, the main thing has been pain in the whole course of the disease.

December 22, 1887. First, galvano-caustique, negative (puncture), 50°, eight minutes. Os high behind pubes, could be touched with the finger tip with great difficulty. The sound could not be introduced into the uterine canal. As I could not introduce the sound into the cervical canal, I punctured the tumor through the vaginal walls with a sharp steel sound to a depth of half an inch. Smart hemorrhage followed the sound's withdrawal, and the vagina was tamponned. December 27th, patient reports that she is much more free from pain than for some months, and that she has no pain at night, and can bear pressure on the abdomen. Second, galvano-caustique, negative puncture, half an inch, 40°, seven and a half minutes.

January 1, 1888, was seized with severe pain in left leg and thigh, with swelling and discoloration. January 2d, leg and thigh swollen and painful. Temperature 100°; morphia subcutaneously was given. In three months the leg was almost well, and the patient was more comfortable than before treatment. She could lie on her side, and could turn over easier in bed, and could walk better, and could bear pressure on her abdomen better. Her size was not larger. She declined further treatment by electrolysis.

October, 1890. Feel some better the last six months. For two years after treatment size of tumor seemed to increase; the last six months it seemed to remain about the same. Menstruation irregular, profuse for two years following treatment, painful. I feel some stronger, and am some stouter. Have been very lame for three years, result of injury; am some better. I can stoop a little better. I have pain most of the time. No children. Have had two attacks of very severe peritonitis. I get relief, when I have severe pain, by taking a phenacetine powder.

CASE III. I will narrate this case at length, as a specimen case, and will describe the others more briefly.

Mary D., aged fifty. Two children, youngest twenty-four years old. Came to my office, December 21, 1887. She had a large, globular, symmetrical tumor, filling the abdominal cavity to a point about two inches above the umbilicus. The tumor was very prominent in the pubic region, and then diminished rapidly in size. It was about the size of a man's head, and larger on the right than on the left. The abdominal girth was thirty-six inches. She had begun to have severe uterine hemorrhages in 1881, the flowing lasting at first four or five days, and later six or seven. Her monthly turns were very regular.

December 25th, positive pole in utero, eight minutes, 40°; sound inserted three and a half inches. December 27th, catamenia as usual. December 29th, flowing

severe; more pain than usual; in amount, patient thought, three pints. December 31st, positive pole, nine minutes, 100°; sound inserted four inches in utero.

Flowing ceased January 3, 1888.

January 6th, negative pole, nine minutes, 120°; sound in utero four inches.

Went home on Saturday the 7th.

January 12, 1888, negative pole, nine minutes, 205°. January 18, negative pole, nine minutes, 150°.

Began flowing January 19th severely, so that on the 23d, the vagina was plugged. On the 24th the plug was removed and another substituted. After forty-eight hours this was removed. In the evening of January 25th a chill came on. Temperature 103°. No abdominal tenderness; severe headache; hot douche with phenyle. January 27th, another chill. Patient was removed to Massachusetts General Hospital. Hot douches continued. January 29th, temperature normal; tumor certainly smaller than during menstruation.

March 6th, positive pole in utero four inches, seven minutes, 140°. Since last visit has had several attacks of severe flooding, for which vagina was plugged. Has been twice in the hospital. The tumor varies in size from day to day, being at one time larger, at another smaller. March 10th, positive pole in utero five inches; six minutes, 175°. March 13th, positive pole, seven minutes, 180°. In utero five and a quarter inches. March 14th, patient feels more comfortable when lying down. Has less tightness in her bowels; formerly felt as if a rubber band was tied round her abdomen. Not so much pain. Less frequent micturition; bowels softer. March 17th, entered hospital at expected catamenial period. March 18th, flowing profuse. March 19th, flowing very profuse, and tumor swollen. March 20th, less flowing; tumor smaller. On the whole this period was one of less flowing than the last. March 21st, more flowing, and 22d still more. March 23d, flowing ceased. March 30th, positive pole, six inches, six minutes, 140°.

April 2d, positive, four and one-half inches, six minutes, 140°. April 6th, positive, four and one-half inches, six minutes, 160°. April 10th, positive, four inches, seven minutes, 175°. April 14th, entered hospital again, but the flowing was not very severe; tumor swollen. April 24th, positive, four and three-quarters inches, six minutes, 140°; ergot after treatment. April 27th, positive, three and one-half inches, five minutes, 110°; ergot after treatment.

May 4th, positive, four and one-half inches, 110°; ergot. Pain in left side after treatment, remained in bed twelve hours. Hemorrhage at sitting checked by positive pole. May 8th, positive pole, six minutes, four and one-half inches, 140°; ergot. May 11th, entered Massachusetts General Hospital and remained till the 18th. Flowing less in amount than ever before. May 22d, positive, 100°, five minutes; depth in utero four and one-half inches; ergot. May 25th, positive, 120°, six minutes; depth of insertion four and one-half inches. May 29th, to-day the tumor feels smaller, but it changes much.

June 21st, reports her last period better than usual, less flowing. The period in June was as bad as ever. Twenty-one treatments had now been given extending over a period of six months, and no great improvement had been noticed. In size the tumor was no smaller, and the hemorrhage on the average, as far as I could see, was neither better nor worse. As Mrs. D. could

ill afford to remain in Boston, and as the effects of the treatment were said to continue after giving them up, I concluded to let her go home and see if any good effects came on.

During the summer and autumn of 1888, I had many letters from Mrs. D., some encouraging and some not. She suffered pain most of the time, and was greatly distended in the abdomen. Occasionally morphine was required.

April 18, 1889. Treatment was resumed. The gas-carbon electrode was put in the uterus to a depth of four and one-half inches, and its position was changed by withdrawing it about an inch four times: first, five minutes, 200°, the negative pole was used as the tumor had increased in size; next 195°, and last 150°; in all twenty-five minutes.

Patient states that she feels better after and is relieved by flowing.

April 22d, gas-carbon, withdrawn an inch at a time four times; making five applications of five minutes each; in all twenty-five minutes, 210°. April 25th and 28th, the same.

June 6th, platinum sound in utero seven inches (it will be noticed that the depth of the uterus had increased); 220°, five minutes. Considerable hemorrhage. Tumor was larger. I did not see the patient again till February 4, 1890. Her umbilical girth was then forty-two and one-half inches, a gain of six and one-half inches since the beginning of the Apostoli treatment, two years and a half before. In size the tumor was much larger, reaching nearly to the ensiform cartilage, and filling the abdomen almost completely. She reported that she had flowed badly in July, September, and November, 1889, and had been in bed sometimes for two weeks.

February 4, 1890. Treatment resumed. Negative pole, because the tumor had increased in size, and because the patient felt better when she flowed pretty freely. Gas-carbon electrode; twenty minutes, 160°; inserted eight inches. Quite a little hemorrhage, with large clots.

February 7th, gas carbon electrode, fifteen minutes; negative pole; considerable pain; 142°; slight hemorrhage. February 11th, platinum sound, seven minutes; positive pole; no pain; some hemorrhage; 320°. I think this is very improbable, and that the galvanometer was inaccurate, but that was what it registered. February 14th, gas-carbon; 280°, fourteen minutes; positive pole. No pain; considerable hemorrhage. February 21st, sound in utero seven and one-half inches; positive pole, 175°, twelve minutes; slight hemorrhage.

March 4th, sound in utero eight inches; positive pole, 210°, ten minutes. March 18th, positive pole, ten minutes, 170°; depth seven inches. March 21st, positive pole, 320°, ten minutes; inserted six and one-half inches. March 25th, positive pole, 230°, ten minutes; depth six and one-half inches. March 28th, positive pole, 290°, fifteen minutes; depth six and one-half inches; considerable pain and hemorrhage.

April 4th, positive pole, 270°, ten minutes; depth six inches; no pain; no hemorrhage. April 8th, positive pole, 175°, ten minutes; depth five inches. April 11th, positive pole, 100°, ten minutes; depth three inches.

I append three letters, one from Mrs. D.'s daughter, written on September 19, 1890, and two from Mrs. D. herself, written later.

Size of tumor increased. Menstruation regular, profuse, painful. Weaker. Fat increased. I am in extreme pain in walking; cannot stoop better. There is no improvement in these respects. I have pain most of the time. No children. Treatment: Magnesia. I was suffering extremely before I left Boston, and tried Dr. Richardson, Waverley House, and it was a great injury to me; it made me very nervous. I tried another; he gave two treatments, and he relieved me very much for a while.

BIDDEFORD, Me., September 19, 1890.

DEAR SIR: Mrs. D. has been sick since the fourth of August. She has suffered more, and had more hemorrhage than ever. She is very weak, and her heart troubles her a great deal. We don't allow any one to talk with her. She had ergot injected in her arm during her last sickness. The noise disturbs her very much. For eight days and nights she had some one to stand over her. She never can survive another sickness. She is improving very slowly now. Yours truly, N. M. D.

BIDDEFORD, October 19, 1890.

MY DEAR DR. HOMANS: I have had a very sick time since the first of August. Had more hemorrhage and more pain, and was weaker than ever before. They had hard work to keep life in me. I did not think I should ever rally, but I have been up a week. Dr. Davis told me that I must know that I could not live long as I was, and wanted Dr. Hill to make a diagnosis of my case. He came the 30th of September. He said there were too many adhesions, and I would not live through an operation. I am growing more uncomfortable every day; my feet and legs swelling more and more every day. It will be time for me to be sick the 30th of this month; and after a day or two the swelling goes down. When I *suffer too much* I take morphine. What else can I do? With gratitude,

Yours truly, M. D.

I hope I shall not have to take any more ergot; it makes me feel dreadfully; it makes me sick to think of it.

January 1, 1891.

MY DEAR DOCTOR: I have had no flowing in December, and I am in a very uncomfortable condition at present. Have been growing larger every day for ten days. I am in about the same condition you found me in last winter when I came to see you. After my sickness the first of November, I was left very weak; flowed six days, but I was very small. The tumor diminished every day for about three weeks, and I gained in strength every day, and I felt like a new person. I could walk and feel quite comfortable. I thought it would never trouble me again. I have not been so easy since two years last November. I diminished around the waist from thirty-nine to thirty-one inches; around the tumor from forty-six to thirty-eight inches. I feel disappointed again. Yours truly, M. D.

I have given this case at length because the treatment has extended over a greater length of time than in any other case, and because I cannot see that it has been of much, if any, use. The tumor has nearly doubled in size; the feet and legs are swollen; and the hemorrhage, although less, is troublesome except as it gives relief. Sometimes she is free from pain, and sometimes not. She certainly has been very patient; and both she and I have given the treatment a fair trial, and without more encouragement it seems a waste of time to go on.

CASE IV. Mrs. T., forty-seven. Youngest child twelve years old. First noticed enlargement in May, 1887. Has increased rapidly in size. Tumor now (December 27, 1887) hard, extending from near the middle of Poupart's ligament on the left to a point midway between the right anterior spine and the right costal cartilage. It extends an inch above the umbilicus, and a movable. The uterine depth is three and one half inches. First treatment, December 27, 1887; 30, nine minutes; negative pole in utero. Second

treatment, January 20, 1888. Reports that she can stoop and move about better. She had twelve treatments between December 27, 1887, and April 2, 1888. Her general health was improved. The size of the tumor was not affected, and her monthly flowing was increased.

Health fairly good. Don't know as the size of the tumor is any different, but am not bloated as I was. Menstruation ceased entirely. Am stronger; am not stouter. Can walk and stoop better; in these respects very great improvement. No pain. No children. Treatment: Have been using a patent medicine, and it has done wonders for me; have been using it since two years last July. Mrs. Pratt recommended it to me. She has been using it longer than I have.

CASE V. Miss R., thirty-seven, librarian. Tumor hard, and extending from the pubes, which it touches, to within an inch of the umbilicus, situated more on the right side of the abdomen than on the left. First galvano-caustique, negative, January 6, 1888. Sound in utero three inches; 50°, nine minutes. The negative pole was in the uterus for eight treatments, 35° to 120°, from January 6th till April 27th. At this time she reported that she had had more profuse and prolonged menstruation, and the positive pole was substituted in the uterus during three applications, from 120° to 100°, till June 14th. After that I used the negative pole again for eight treatments. In all she had nineteen applications during ten months, and was better and worse. On the whole, at the end of the treatment, the tumor did not appear either larger or smaller, and there was more flowing, but she could walk better than before taking the electricity, and had been somewhat improved by the treatment. It will be seen, however, that the tumor has since increased decidedly.

October, 1890. Health not as good as one year ago. Tumor increased in size. Menstruation regular, not profuse, nor scanty; painful; am somewhat weaker after flowing ceases. Fat not increased. I can walk and stoop better than before treatment. Have pain much of the time. No treatment since seeing you.

CASE VI. Mrs. V., thirty-six years old. No children. Catamenia regular, rather profuse. Tumor noticed a year ago. Now, February 14, 1888, it extends from near the middle of Poupart's ligament on the left, to within three inches of the right anterior spine of the ilium, and in the centre of the abdomen to the umbilicus. First galvano-caustique, negative, February 14, 1888; 60°, six minutes. Sound in the utero. Second application, February 18th. The rheostat had become wet, and when the pieces of sponge struck the water, quite a shock was given and considerable pain. Dosage 50°, six minutes. After the application she suffered pain, and was feverish. February 23d: has not felt well since last application. Uterus now fixed, vaginal roof vaulted; apparently there is some pelvic effusion. Treatment suspended for the present.

Health excellent. Steady increase in size of tumor up to last May; steady decrease since then. Menstruation regular, profuse; not painful. Am stronger; am not stouter. Can walk better; can stoop as well as ever I could. Have no pain. No children. Treatment: Dr. — has been treating me. I have been taking pills made from the enclosed prescription<sup>2</sup> for the last six months, and have made rapid improvement during that time. Habitual discharge of leucorrhoea ceased. Monthly sickness less profuse during last six months.

CASE VII. Mrs. K., forty-six. Youngest child eighteen years old. Has considerable abdominal pain and profuse monthly flowing. Os uteri much fissured, large and hard. There is apparently a fibroid growth from the right side of the fundus.

<sup>2</sup> R. Ergotin, enclonad, sulph., gelsendi rad. poly., 55 gr. i. M. One after meals.

February 18, 1888. First galvano-caustique, negative, 75°, seven minutes. Sound in utero. Five more similar applications were made until April 3d, in doses from 70° to 100°. Her pain and general discomfort were much less, and her health was improved; locomotion was easier.

On April 3d, did not feel as well, and had more flowing, consequently the positive pole was put in the uterus; dosage 110°. After this the negative applications were resumed. On May 15th she reported that she felt stronger and could work better. Went eight weeks without any flowing. On May 22d reports the existence of a whitish-brown discharge from the uterus for the last fifteen days. She discontinues treatment for the present on account of the inconvenience of attending the clinic.

She had seventeen treatments, in doses of from 50° to 110° for five or six minutes, all negative but one. The relief to her pain and her increased ability to walk were marked. The tumor was unaltered in size. No answer was received to circular.

CASE VIII. Mrs. A., thirty-five. Never pregnant. Health good. Excessive flowing through the summer of 1887, and since October hemorrhage every month for two weeks. No pain except at menstrual periods. On examination, March, 1888, uterus large, containing a fibroid in the posterior wall; os thin as paper, and neck obliterated; os admits tip of finger. Cannot walk up stairs without resting.

March 6, 1888. First galvano-caustique, positive. Sound in utero, 60°; same dose repeated on March 10th and March 17th, when she reported that she felt better than she had for a long time, and that the flowing had entirely ceased. She can run up and down stairs.

This patient had eleven applications, positive, from March 6th to April 10th, in doses varying from 60° to 135°, for six minutes, and was completely relieved from her flowing, pain and inability to walk. A most brilliant case. Tumor somewhat smaller apparently.

March 21, 1890. Presented herself for treatment again; was well till July, 1889, when she had excessive flowing, lasting for five weeks. Has had two attacks since; has lost thirty pounds of flesh and is pale and sallow. No especial change in tumor. After four galvano-caustique treatments, of the same character as those described above, she felt better in every way; the last period was more comfortable, but the flowing was not affected. Subsequently the uterine canal was dilated, and its interior curetted and painted with iodine. After this the hemorrhage diminished and her health improved. In this case temporary improvement followed electrolysis, but as much or more improvement followed curetting, and the tonic effect of the electricity could be obtained by a more simple method than that of Dr. Apostoli.

CASE IX. March 24th, 1888. Mrs. B., forty-eight, youngest child thirteen. In August, 1887, had some pain in right side, and noticed swelling, which steadily increased in size. Catamenia irregular; urine at times turbid and offensive. Fibroid half again as large as closed fist, situated in anterior wall of fundus, somewhat towards the right. Os and neck large, thick and fissured. Uterine cavity four and one-half inches in depth. After four treatments with the negative pole in uterus, dosage from 100° to 225°, the tumor was certainly less than half its former size, and all symptoms caused by it had disappeared. May, 1889,

patient in good condition. Tumor has remained small, but menorrhagia has appeared, a new symptom.

October 4, 1890.

DEAR DR. HOMANS: In response to your letter asking for information concerning Mrs. B.'s condition since your treatment, I would say, that the menorrhagia continued for about two years subsequent; sometimes very free, and at other times not much more than an ordinary menstrual flow. The turns were irregular. The tumor during this time varied much as to size, etc. If you remember, it was reduced to about the size of a peach when she left Boston. It has since been as large as a goose egg, and this increase was accompanied with lumbar pain, cystic irritation, etc. At the present time the tumor is scarcely to be detected; indeed, since the flow ceased (now eight months), the size of the tumor has almost continuously decreased, until at present there is no trouble with it at all. The general health is better, and the cystic trouble has disappeared.

Now, doctor, whether it be a case of *post hoc ergo propter hoc*, I don't know; but I think the treatment gave the start towards recovery, and the menopause, being about to occur, helped on the amendment. Anyhow, Mrs. B. and myself are thankful beyond words to you for your great kindness.

My wife desires to be remembered, and asking you to excuse the way and manner of this hurried note,

I remain, Yours truly, ———.

I cannot see that this case was very much affected. It is true the patient improved, but the menopause was the main factor in the cure.

CASE X. Mrs. D., thirty-two. One miscarriage at six months, some fourteen months ago, since when menses excessive. Fibroid, about size of small infant's head, extends to within an inch of umbilicus. Semi-circumference of tumor covered by abdominal walls, seven and a half inches. Os points back towards sacrum, the weight of the tumor having tipped the fundus forward and the neck and os back. Uterine cavity four inches in depth.

First treatment, negative pole, April 10, 1888, 50°. Five treatments given till May 1st, dosage increased to 95°. On May 4th, seized with violent flowing, in fact, hemorrhage, which lasted till May 10th. On May 15th, positive pole was used in utero, dosage of 90°. This repeated twice, on May 18th and 29th, each time with much flowing after treatment. Ergot, half drachm, three times daily.

Five inches is now semi-circumference of tumor, which seems to have retracted about an inch on right side, and one and one-quarter inches on left side and in the middle. Flowing: a little bright-red blood every day.

Electrolysis combined with ergot must be given the credit for having caused much improvement in this case.

October, 1890. Health good. Tumor decreased. Menstruation regular most of the time; not painful. Am stronger. Fat over the stomach not increased, but some stouter all over the body. Can walk better. Have no pain. No children. No treatment.

CASE XI. April 13, 1888. Mrs. D., forty-five. No children. Has passed the menopause. Abdomen much swollen with gas. Fibroid, size of child's head, completely filling pelvis, and pressing on rectum and urethra so as to necessitate frequent use of catheter. Sound passed three and one-half inches and negative pole used in utero. Eleven treatments given between April 13th and May 29th, negative pole, dosage from 50° to 130°. Considerable diminution in size of tumor, and entire disappearance of all difficulty in micturition.

She remained well all summer, but returned on October 9th, having been obliged to use catheter occasionally for two weeks. Tumor felt with difficulty, except by pressing deeply into the pelvis. Four treatments from 9th to 30th October, as before, dosage  $95^{\circ}$  to  $150^{\circ}$ .

In this case electrolysis was certainly of advantage, and combined with the occurrence of the menopause, has nearly cured this patient.

October, 1890. Health pretty good. Size of tumor about same. Menstruation has stopped for a year. Am stronger. Fat about same. Have never been troubled about walking or stooping. A little pain sometimes. No children. No treatment, except to have water drawn twice about a year ago. There is soreness sometimes on outside.

CASE XII. Mrs. B., thirty-four. Never pregnant. Has sensation of soreness and fullness in the lower abdomen, and feels weak. Flowed somewhat a few months ago, but catamenia as a rule regular and normal. A hard, movable fibroid, size of infant's head, extends to within one and one-half inches of umbilicus. Uterine cavity three and one-half inches deep. On 20th and 24th of April, 1888, treatments of five minutes each, negative pole, dosage  $50^{\circ}$  and  $70^{\circ}$ . On April 27th catamenia more profuse and painful than usual, lasting seven days instead of five. From May 4th to July 21st twelve more treatments, negative pole, dosage from  $85^{\circ}$  to  $120^{\circ}$ . At last treatment a well-marked papular eruption on abdomen, on the space covered by the clay. On July 22d began to flow; flowed profusely eleven days, more than ever before.

October, 1890. Health very good. Size of tumor about one-third larger I think. Menstruation regular, rather scanty, not painful. Am stronger, am stouter. Can walk and stoop better. When very tired, a heavy, distressed feeling where the tumor is. No children. Treatment: The Brinkerhoff system for rectal troubles.

CASE XIII. Mrs. F., forty-five. Youngest child thirteen years old. Movable fibroid extending above umbilicus, with outlying knobs; fills vagina and pelvis largely. No pain.

On April 20, 1888, the introduction of the sound to the depth of two inches was followed by excessive hemorrhage, which was not controlled by the positive pole in utero, the dose of  $80^{\circ}$  being given for five minutes. Patient remained in bed at the hospital for two days, then went home. She died of pneumonia May 20, 1888. There is no reason to suppose that the treatment was the cause of her death.

CASE XIV. Mrs. B., forty-four. One child, nineteen years old. Has known she had a tumor for eight years. Cannot stand any length of time owing to bearing-down pain. Is easily tired. Appetite and sleep poor. Tenderness at times over all the abdomen. Catamenia profuse, regular. Tumor hard, reaching to umbilicus, and from a finger's breadth from right anterior spine to within two fingers' breadth on left anterior spine.

From April 24th to June 30, 1888, nine treatments, the first four with negative, then five with positive pole, duration five minutes; dosage from  $60^{\circ}$  to  $120^{\circ}$ ; and inserted four and one-quarter inches.

On July 30th can stand better and longer; walks better. More appetite. Tumor smaller.

October 23d, better than when first seen, but still the same. Two treatments, one with gas-carbon and three applications of three minutes each, the sound being within an inch between each application. (See Case I.)

January 1st, 1891. Health much improved. Tumor smaller. Fat in umbilico-pubic region much

thicker than before treatment. Tumor about same size, certainly no larger. Catamenia normal. No hemorrhage.

January 7, 1890. Condition about the same, but is nervous and uncomfortable. Four treatments from January 7th to 24th, three with platinum, one with gas-carbon sound (two applications), duration ten minutes, dosage  $70^{\circ}$  to  $120^{\circ}$ .

Reported favorably November 6, 1890. Very much helped by electrolysis. Is much stronger; walks better. No flowing or pain. Always better after treatment.

Health improved. Size of tumor remains about the same. Menstruation regular, not profuse, nor scanty, nor painful. Am stronger; am stouter. No particular improvement in walking or stooping. No pain. No children. No treatment.

CASE XV. Miss W., thirty-nine. Noticed tumor two years ago. Catamenia regular. No hemorrhage. Hard, solid, movable fibroid, filling the pelvis from before backwards, of irregular shape, extending to umbilicus and with a semi-circumference of seven and one-half inches.

From April 24 to May 29, 1888, seven treatments. Platinum sound inserted one and one-half inches, negative pole, six minutes duration, dosage  $60^{\circ}$  to  $150^{\circ}$ . On May 30th she was seized with pain in abdomen, and felt very weak. May 31st, more comfortable. June 1st, abdomen sore to the touch and on movement. Disinclined to move in bed. No appetite. Much offensive uterine discharge. Improved a little and went to seashore on June 21st.

June, 1890. The uterine discharge still exists. Tumor larger.

December 4, 1890, health good. No change in size of tumor. Menstruation regular; not scanty, nor painful; not profuse. Am stronger. Fat over the stomach not increased; am thinner. Can walk and stoop better. No pain. No treatment, nor has she taken any medicine. Is cooking regularly. Thinks the treatment benefited her.

CASE XVI. Mrs. C., thirty-four. Has been in poor health for ten years, since the birth of her youngest child. Much pain in back, left side, and leg, headache, difficulty in walking, insomnia. Has consulted many doctors and had many different treatments. In left side of pelvis is a small hard mass, apparently connected with the uterus which is fixed, immovable and tender.

From 27th of April to 29th May, 1888, seven treatments, sound inserted two and one-half inches; negative pole, duration five minutes, dosage  $45^{\circ}$  to  $60^{\circ}$ . Patient suffered considerable pain, hence the low dosage. Walks much better. No headache at all. Pelvic induration less. Still some pain in leg.

Circular unanswered. This case does not seem to be certainly one of fibroid tumor, but electrolysis helped the patient apparently.

CASE XVII. Miss F., forty-one. The fibroid has been present for five years, has grown rapidly in last six months, and now extends four inches above umbilicus and from one anterior spine to the other. Dyspnea. Swelling of feet. No great hemorrhage, but menses last longer than normal.

Two treatments, April 27 and May 8, 1888. Sound inserted two inches; negative pole, duration five minutes, dosage  $50^{\circ}$  to  $75^{\circ}$ . Never returned for more treatment. Circular unanswered.

CASE XVIII. Mrs. L., forty-seven. Healthy and stout. Excessive flowing at catamenial periods. Clots come out, and then blood pours as if from a bottle just

uncorked. No pain nor tenderness. Constipation. Fibroid, size of small orange, situated in posterior wall of uterus, and wedged down between bladder, uterus and rectum.

From May 21 to June 21, 1888, seven treatments; sound introduced three inches; positive pole, duration six minutes, dosage  $55^{\circ}$  to  $140^{\circ}$ . At next catamenial period, a prolonged flowing, longer and more profuse than before treatment. Since then catamenia normal. From that time on there has been no necessity for taking as many precautions as formerly when unwell, and health generally has improved.

In this case credit must be given to the treatment for having made the catamenial periods painless and normal, with diminished hæmorrhage. Mrs. L., has not consulted a physician on account of any pelvic trouble since the last treatment in June, 1888.

CASE XIX. Miss B., forty-six. Noticed tumor two months ago. No symptom except weight and dragging down of tumor. A hard fibroid, of irregular shape and about size of small coccoaut, occupies pubic region, extends down into Douglas's fossa and thence along lumbar vertebra to umbilicus.

From May 22 to June 21, 1888, six treatments; sound introduced five inches; negative pole used four times, positive twice; duration six minutes, dosage  $50^{\circ}$  to  $70^{\circ}$ . No appreciable effect produced.

October, 1890. Health fairly good. No change in size of tumor. Menstruation regular, profuse. No stronger, am weaker. Fat increased. Am stouter. Cannot walk nor stoop better. No pain. No children. Treatment only for my general health.

CASE XX. Mrs. S., forty-two. General history for past thirteen years, of periods of great pain in back, varied by flowing; hysteria: "nearly insane" at times; trouble in head, etc. Has consulted numerous doctors of both sexes and all schools. During these years has had two confinements, and was well for about a year at one time. Hard fibroid in posterior wall of uterus, projecting towards rectum. From May 22 to June 11, 1888, six treatments; three positive, three negative pole; sound introduced two and three-fourth inches; duration five minutes, dosage  $50^{\circ}$  to  $80^{\circ}$ .

Some slight amelioration of symptoms. Circular not answered.

CASE XXI. Mrs. F., thirty-five. Youngest child three years old. About six years ago began to flow excessively at catamenial period, which lasts ten days, the excessive flowing lasting five days. Within a year grown quite feeble, heart murmur, pallid, tongue whitish, dyspnoea on slightest exertion. An orange-shaped fibroid in anterior wall of uterus tips fundus forward. Uterus has been curetted.

From June 21 to July 31, 1888, six treatments; sound inserted three and one-half inches; positive pole, five minutes duration, dosage  $75^{\circ}$  to  $105^{\circ}$ . After second treatment had watery discharge, not offensive. At close of treatment much improved in general feelings. Catamenia much easier, flowing only three days.

Had malaria during summer, and in autumn reported "flowing same as ever." In September and October three treatments; two as above, dosage  $70^{\circ}$  to  $120^{\circ}$ ; one with gas-carbon sound changed three times, duration in all, six minutes, dosage  $130^{\circ}$  to  $160^{\circ}$ . Very much less flowing at next period.

This patient was very much benefited by the treatment, was made stronger, had less hæmorrhage, and gained in power of locomotion. I think no treatment could have been more satisfactory.

October, 1890. Health fairly good. Apparently no change in size of tumor. Menstruation regular: not as profuse as before treatment. Am stronger. Fat increased; am generally stouter. Can walk better; cannot stoop very much better; in these respects a general improvement. Pain in back, and side-ache at times. No children. No treatment.

CASE XXII. Mrs. Q., forty-two. Youngest child four years. Noticed enlargement about five months ago. Abdomen fleshy. Movable tumors extending above umbilicus on left side.

From June 23 to July 21, 1888, nine treatments. Sound inserted five inches; negative pole, duration five minutes, dosage  $35^{\circ}$  to  $185^{\circ}$ . After second treatment much pain through back of thigh and buttock, and some days after the last treatment had had pain in limbs, was unable to stand, confined to bed. Tumor larger.

October 17, 1890.

DEAR SIR: Your communication was duly received. In reply, I need only say that my mother died December 23, 1888, never once leaving the bed after her return home from St. Elizabeth's Hospital.

Yours respectfully, J. V. Q.

It seems from this note that Mrs. Q., went to St. Elizabeth's Hospital, but perhaps the patient's daughter has confounded St. Margaret's Home, where the electrolysis was administered, with St. Elizabeth's Hospital.

CASE XXIII. Mrs. S., forty-six. No children. Considerable flowing for three years with pains in abdomen and left leg. Tense, lobulated tumor, filling abdominal cavity between each anterior spine, and from pubes to umbilicus, higher at the sides than at umbilicus. Tumor fills vagina; os pushed to one side.

On June 30th and July 3d, sound inserted with difficulty five inches; positive pole, duration five minutes, dosage  $50^{\circ}$ . Three unsuccessful attempts were made after this to introduce sound, but the patient thought she received great benefit from the treatments, although the sound had not been connected with the battery.

In the autumn, from October 9th to November 6th, four punctures,  $3\frac{1}{4}$ ,  $3\frac{1}{4}$ ,  $1\frac{3}{4}$ , 2 inches; duration five minutes, except the third time when pain was so great that only half a minute could be borne; dosage  $35^{\circ}$ ,  $12^{\circ}$ ,  $7^{\circ}$ ,  $11^{\circ}$  to  $20^{\circ}$ . Patient became nervous. Size of tumor not affected.

Circular not answered.

CASE XXIV. Miss W. Catamenia always irregular and painful; absent from August, 1883, to January, 1884. From March to September, 1884, in bed with pelvic cellulitis. Since then difficult micturition and constipation. Life is a burden to her from pain in right side and lower portion of abdomen. This pain is accompanied by vomiting, and is much increased by walking; so for four years she has hardly walked at all. Examination under ether showed uterus small and undeveloped; ovaries normal, rather small. Uterine cavity two inches in depth. On posterior portion of fundus and neck an enlargement about the size of small English walnut; apparently a fibroid, attached to the uterus and movable with it. Has had blisters, iodine, etc., applied.

From July 3 to 28, 1888, seven treatments; sound inserted one and one-half inches; negative pole, duration five minutes, dosage  $65^{\circ}$  to  $90^{\circ}$ . At first she improved, but then the pain returned with a watery discharge. Advised to omit treatment till autumn.

In August had much pain, but then improved rapidly; and after three more treatments in October, like those described above, she menstruated for the first time since

the treatment began, and, to use her own words, "Walk much better, much more comfortable, can do almost what I please. Can pump the organ, which I have not done for years."

October, 1890. Health not as good as when I saw you. Menstruation: Don't have any. No stouter. There was improvement in walking and stooping before I had this sore. Have some pain. No children.

I append a letter from her, written two years after the last treatment, showing that her improvement was temporary, and that the fibroid has very little to do with the case.

October 19, 1890.

DEAR SIR: When I left you, I could work at home, but I have never had any monthly turns since July, 1888.

Now, I cannot do anything. For the week before the Fourth of July I had an ulcer come on the outside of my bowels, on the same side the other trouble was, and it never has healed yet; but the doctor says it is doing well, so, of course, I am way back to where I was when I came to see you. My back troubles me the most, on the right side. The only way I keep my strength is by the use of ale and whiskey. My stomach is not any better than when I saw you. N. P.

P. S. I don't know about the tumor, but have that same discharge, but don't know what it is. Dr. Fields says that he cannot stop it; so I do not know what to write, as I have not consulted with any other doctor but you.

In this case the effect of electricity was decided and beneficial, and the patient's present feeble condition is constitutional and not dependent on any especial local condition.

(To be continued.)

## SEWAGE: APPLICATION TO LAND THE BEST METHOD OF TREATMENT.

BY HENRY J. BARNES, M.D.

BERLIN.

YOU who listened to the introductory address of Virchow last summer at the meeting of the International Congress, have more recent information respecting the sewage farms of this city than I can give. I visited one at Blankenburg. The surface was irregular with hills of considerable height. The soil was black, rich, and thoroughly underdrained. The sewage was delivered at the highest point, and from thence conducted to the several fields. The amount and beauty of the vegetation exceeded anything I have ever seen. I was unable to find stepping room in a field of about ten acres of cabbages. The abundance and variety of vegetables, fruits, and flowers, goes far in proving the correctness of the great agricultural chemist, Liebig, in estimating the value of the detritus of a great city.

I was unable to find more than one spot where offense existed, and this was caused by a break in a temporary carrier. A faint odor of fresh sewage was apparent where the sewage first appeared on the surface, noticeable within a radius of about ten feet, but nothing to be compared with what I have observed in our city on Commonwealth Avenue, resulting from topdressing with the coarse products of the barnyard.

The sewage was very rich and black, for Berlin adopted the principle of *tout à l'égout* in the construction of her sewerage works. Not a privy-vault, or

Read before the Boston Society for Medical Medicine, Pathology and Hygiene, at the Medical and Surgical Society, Suffolk District, Jan. 1, 1891.

cesspool, is permitted within the city limits. Mr. Hobercht, the city engineer, said to me, "the system fulfils all requirements from a sanitary point of view, and nets the city from two-thirds to two and a half per cent. above the cost of operating, after deducting interest on cost of land in use." The labor is performed largely by inmates of public work-houses, which reduces the cost of operating, gives healthful occupation, and tends to the elevation of the laborers.

It is generally admitted at the present time, that chemical plants for the treatment of sewage are costly, inefficient, and generally offensive, and therefore, the last to be adopted in the choice of methods. My observation of a large number justifies this conclusion, and the examples already given of other methods of disposal will enable us to form intelligent opinions as to the best treatment. The possibility of purifying by soil treatment has long been recognized by our profession, and within a few years conclusively demonstrated by our State Board of Health at Lawrence. Profitable nitrification is questioned, and doubt is often expressed as to the safety of employing the human excreta in sewage as a fertilizer, and for these reasons many engineers maintain that a discharge into a water course, or tidal basin, if available, is the cheapest and best way to get rid of it, other things being equal.

With the exception of Pasteur and Dr. Hope, of Liverpool, I know of no English, French or German authority holding this opinion.

Dr. Corfield says, the effects from sending sewage into rivers is worse than a waste, being injurious from many points of view. Durand-Claye wrote of the system of Dantzic: "It is of much credit to the municipality that although the town is surrounded by rivers of large size, and lies within three miles of the sea, it has rejected the false and barbarous custom of casting untreated sewage into sea or river. The Royal Commissioners sum up a mass of evidence which includes the best English authorities in stating that "it is admitted by all that a mixture of crude sewage with sea-water gives rise to very offensive smells. . . . Wherever the sewage is discharged into sea-water, whether the sewage be crude or precipitated, these smells may be expected to arise. . . . It is next to impossible, that the discharge of matter of so offensive and putrescible a character, can be effected without tending to produce grave evils in the places where they become exposed. Whether the sewage be discharged into the sea, or into tidal estuaries, or into inland running streams, these evils must always be present in a greater or less degree. In what would seem to be the most favorable cases, namely, a discharge upon the sea coast, great nuisance often occurs, while in tidal rivers, or running streams, the defilement and pollution are often such as to cause mischief of an alarming character."

Mr. Aird says: "The ruling authorities in Germany know that sewage irrigation can be carried out without causing any nuisance; that purification of sewage by sewage irrigation is of immense importance to public health and the state of the rivers, and therefore they declare it permissible anywhere."

It is unnecessary to remind you, that in this country objectionable features exist where sewage is discharged into water, and while I admit that local conditions must always govern the choice of methods of disposal, I contend that owing to these objections a discharge into water should not be our first choice, either from a sanitary or economic point of view, and is only per-

missible after every effort has been exhausted to find available fields within reasonable distance, where one of the three methods of soil treatment could be employed.

Irrigation accomplishes the best results, and insures the largest return in utilizing the sewage. The principal features are an intermittent discharge on well-drained, permeable soil. Under such a condition the sewage soon disappears. The matter in suspension is arrested by filtration.

The alumina and the silicates of the soil act as precipitates. The soluble and insoluble organic matter is reduced to inorganic by a process of nitrification dependent on the presence and activity of micro-organisms, and finally utilized by vegetation under intensive culture.

Broad irrigation is an intermittent flow over the surface of a comparatively impervious soil. Reduction of the organic matter by the microbes of nitrification and appropriated by vegetation.

Intermittent filtration differs from irrigation only that the name does not imply utilization. The author of the system, Bailey Denton, makes no distinction between it and irrigation. Filtration, precipitation, and digestion by living organisms are common to all three. Anæsthetics, antiseptics, or boiling, will suspend reduction, showing that physiological agencies are the most important.

The microbes of nitrification are most abundant in the air, and the first few inches of vegetable mould. Here the number and variety increase in proportion to the richness of the soil. In fresh sand they are very scanty, but in it colonies are easily cultivated if nutritive material is supplied, as shown by the intermittent filtration experiments of our State Board, where inorganic filtering material, fresh from the sandbank, proved of little value for purifying purposes until stocked with micro-organisms. The filters designed by Koch, and employed at the Berlin water-works, intentionally, are stocked with as many colonies of bacteria as possible, with the object of reducing the soluble organic matter. The microbes of nitrification which Schloesing and Muntz have described as round organisms are not the only ones which enjoy this property.

"Mr. Cohn has shown that the reduction of sulphates into sulphuretted hydrogen and sulphur, and nitrates into nitrites, ammonia and nitrogen gas, is accomplished through the agency of microbes. Heraseus has demonstrated the action of a number of species, among them the bacillus-prodigiosus, the spirillus of Denke, the spirillus of Finkler, the bacillus of typhoid, the bacillus of the charbon, and the staphylococci possess the property of oxidizing ammonia and transferring it into nitrous acid, and two bacilli found in water reduce the nitrates." Reduction can be and is accomplished in the laboratory by chemical agents, but in nature the process is slow, the chemicals not being present in sufficient abundance, and when artificially supplied the generation of offensive gases usually result. Reduction by physiological processes in the soil is not usually a putrefactive change, as is often proved by a well-managed earth-closet; and if offensive gases are generated, their combination with elements present in the soil prevent their escape.

The usual practice of storing and transporting fertilizers, during the putrefactive change, is attended by a loss of ammonia, sulphuretted hydrogen, and car-

bonic-acid gas, and impairs the value of the fertilizer, fairly measured by the offensive odor created.

In regard to the possibility of polluting the soil and thus establishing a culture field for pathogenic germs, Pasteur expressed grave apprehensions in a letter addressed to a commission of the Chambers of Deputies. He considered the fulfilment of the project to spread the drain-water of Paris on the cultivated lands of Saint Germain a serious menace to the inhabitants dwelling on the land, and also to the citizens of Paris. In considering this danger the Commission visited the irrigation fields of Berlin, assisted by Virchow, Koch and Hobercht. The subject was studied in other Continental cities, and from 144 cities and towns of Great Britain information was gathered, but so far as could be learned, not a single example of disease resulting from soil treatment could be obtained, and the Commission concludes:

"What becomes of all the pathogenic germs consigned to the soil with fertilizing agents, the science of bacteriology is not sufficiently advanced at the present time to declare. That they do not preserve their primitive virulence indefinitely, even in nutritive fields most favorable for their development is well known, and well illustrated by one of Pasteur's most beautiful discoveries of the transformation of the virus of cholera into a preservative vaccine. Light and the sun's rays are fatal to some; others perish in what Professor Bouchard calls the bactericidal substances they secrete, or are consumed in the presence of natural enemies. What becomes of durable spores of pathogenic origin in the midst of the combustion of organic matter taking place under the influence of the air and the microbes of nitrification, where sewage is spread on cultivated fields, is not as yet completely determined; but from what we do know of microbiology, the earth, which has always been the receptacle of pathogenic microbes, is also their great cemetery, and in the field of microbiology M. Pasteur cannot prove the reality of his fears."

Dr. Corfield refers to the 4,000 acres under irrigation about Milan, a part being within the city limits, and confessedly "turned into water meadows" (a result of excessive irrigation), as presenting no evidence whatever of increased injurious tendency of the irrigations conducted with the waters of the Vettabbia over those of other districts where plain water is employed, and on one farm watered entirely by the Vettabbia, not a case of cholera occurred during three epidemics in the city.

It must, however, be admitted, that the application of crude sewage to the foliage of vegetation is not without danger, particularly if the vegetables or fruits are eaten without cooking. Pathogenic germs may lodge on a stalk of celery or adhere to a radish or water-cress, and through neglect or carelessness in washing be taken into the alimentary canal, and a sporadic case of disease result; but if sewage is to be rejected as a fertilizer on this account, to be logical, the employment of nearly all fertilizers should be interdicted. The excreta of beasts and birds may contain the ova or organisms themselves, dangerous to man. The Chinese have but few domestic animals, and depend almost wholly on human excreta. As a consequence of the filthy habit of applying slops to the foliage of growing vegetation intestinal worms are very common among the people; otherwise they are more free from zymotic diseases than European nations.

Paludal conditions may be established by overburdening land with sewage or even pure water. In the early history of the Gennévilliers farm an accident of this nature occurred, for which the city of Paris was obliged to pay large indemnities. Offences are created where sewage is permitted to stand on the surface. The open carriers are foul smelling, if deposit is allowed to accumulate and remain on the bottom or sides. If the sewage is not delivered fresh there is a nuisance. Ignorance, carelessness, or accident, are responsible wherever these conditions exist, and they can be, and are prevented, on well-conducted farms.

I have yet to see the sewage farm where offensive conditions are caused by the richness of the sewage. Excessive fertilization is practically unknown in agriculture, although, from an economic point of view, the limit is often reached. Too rank a growth of rye, or clover, often impairs the value of the crop on soils enriched by sewage or the products of the barnyard. It is, therefore, the amount of water land is capable of disposing of without becoming water-logged, that fixes the limit to the employment of sewage.

The stiff clay soils and generally moist climate of England are conditions unfavorable for the purification of a large volume to the acre. On the Continent, lighter soils and a drier atmosphere render it possible. For example, 3,500,000 gallons per acre per year tested the full capacity of the soil of the Croydon sewage farm, while on an experimental field of fifty hectares near Paris 12,000,000 gallons per acre per year was reached, without making the soil marshy or offensive. Assuming 30,000,000 gallons per day to be the average flow of the sewage of Boston, it would require 817½ acres under similar conditions. Our State Board has demonstrated the capacity of an intermittent filtration tank to be equivalent to 8,600,000 gallons per acre per year, without the aid of vegetation, which is known to absorb and exhale large volumes of water. For example, a full size cabbage will absorb and throw off a pailful of water in a day. At the above rates it would require only 1,281 acres to purify the sewage of Boston—which is in striking contrast with an engineer's estimate of "a necessary area nearly as large as the township of Brookline," which includes 3,840 acres, and which he also states must be comparatively level.

The volume of liquid, not the richness, governs the number of inhabitants to the acre employed to purify their wastes, which in England varies from 100—"an arbitrary limit from unknown causes" (Royal Commission Report)—to 1,000, Bailey Denton's opinion; 3,000, Dr. Frankland's; and 5,000 to 7,000, Dr. Tolp.

Prejudice exists against the use of vegetables raised on land enriched by night soil, notwithstanding the fact that science has long since demonstrated, that from whatever source the fertilizer is obtained, it must be dissolved, and with few exceptions, resolved into its component inorganic elements before it is available as a plant food. The products of the barnyard, water-cress, privy-vault, or the guano heap, to be serviceable must be decomposed into gaseous elements to enter the circulation of parts through the respiratory apparatus of soil and held in solution that the roots may imbibe. The carbonic acid, hydrogen, oxygen and nitrogen, carbonic acid, and the carbonic acid, nitrogen, ammonia, and earthy minerals it casts, to secure the most prompt growth, should relieve us of

any feeling of disgust as to the source from which its nourishment is obtained.

In view of the benefits derived by our garden farmers who establish and maintain at their own expense plants for pumping water on fields irregular as to contour, and often underdrained, in consideration of the lift often necessary before sewage can be thrown away, it seems unreasonable to maintain that sewage cannot be profitably utilized under such conditions, for dissolved in this liquid are all the fertilizing elements necessary in the growth of vegetation.<sup>2</sup> At Edinburgh and Dantzic it has converted land so poor as to furnish only the necessary mechanical support to vegetation, into agricultural fields from which the owner at Edinburgh receives in rentals \$125 to \$150 per acre, and Mr. Aird at Dantzic, from \$20 to \$100. "It is a curious sight," says Durand-Claye, "to see, surrounded by irregular dunes of blowing sea-sand, vast spaces covered with a vigorous vegetation as a result of the application of sewage."

We may therefore accept the conclusions of the Royal Commission on the general subject of sewage disposal, with a feeling of certainty that our soil and climate is more favorable for purification and utilization of sewage than that of England. Of soil treatment the Commission reports: "Although there are many points in regard to this system in which the authorities differ in opinion, there can be no doubt of the general conclusion that the result of experience, and of the investigation of the subject by the most competent authorities, have been strongly, and almost unanimously, in favor of the application to land as in every way the best, and most advisable mode of treating sewage, *where circumstances will admit of its use.*"

Time will permit of but brief allusion to local conditions.

April 14, 1870, physicians of Boston addressed to the municipal authorities a remonstrance against the existing sanitary condition of the city, and urged the necessity of a better system of sewerage. March 1, 1875, a commission was appointed consisting of Messrs. E. S. Chesbrough, C. E., Moses Lane, C. E., and Dr. Charles F. Folsom. These eminent men devised the main drainage system of our city, opened January 1, 1881. It has proved of great sanitary advantage to the city, and the views presented in this paper on the general subject of sewage disposal are not intended as reflections on the wisdom of this Commission, for had the great progress in soil purification since the establishment of the works been anticipated, it is doubtful if a better point of discharge could have been selected for extending the works with the object of utilizing the sewage on land.

Through no fault of the projectors of the system, experience is teaching that serious errors in carrying out the details of the work are being committed. The first year the system was in operation twenty-four times it was overburdened by storm water. Since that time sixty miles at least of storm-water sewers have been added, and although no record is kept as to the length of time, or number of times it now overflows, I am informed by gentlemen having charge, that practically with every storm a discharge of sewage takes place along our water front. With the rapidly increasing population of the city and the extension now under construction, designed to accommodate the in-

<sup>2</sup> A garden farmer, in Arlington, has offered the town \$600 a year for the use of the town water on his land.

habitants of Waltham, Newton, Watertown, Brookline and Brighton, large volumes of sewage must in time of storm be discharged into the Charles River basin or conducted to the outfall and greatly embarrass if not defeat, the success of any purifying process. In the interest of economy and the sanitation of the river and upper harbor, it is high time we ceased to construct what is known as the combined system, and adopt what Col. Waring introduced at Memphis and known as the "separate system."

It seems the height of folly to conduct the rain water which falls on the roof of my house to the pumping plant at the cow-pasture, where it must be elevated thirty-two feet before it can be disposed of, when it might be discharged by gravitation in a natural water-course within two hundred feet.

The object of this paper will be realized if, in the future development of our city, we preserve from encroachment our natural drainage for storm water, and our State Board of Health is authorized to conduct experiments in the utilization of sewage.

## Clinical Department.

### A CASE OF PENETRATING WOUND OF THE ABDOMEN AND THORAX: RECOVERY.

BY J. T. MOORE, M.D., PORTLAND, OREGON.

On the evening of February 4th, C. K., age twenty-four, applied to me for treatment of a knife wound which he had just received upon the street from the hand of a murderous assailant. He was in a state of partial syncope, but never lost consciousness.

Upon examining the wound, I found an incision, about one inch in length, extending laterally along the lower border of the twelfth rib, and a little in front of axillary line. The wound bled freely, but hemorrhage yielded to applications of hot aseptic solutions.

Upon exploring the wound my probe passed to a depth of four inches obliquely inwards and upwards. I was satisfied from the location of the wound externally and the direction it took that both cavities, abdominal and thoracic, had been opened into; the former directly from without, and the latter by extension of the blade through the diaphragm. Assisted by Dr. McKenzie of this city, I dressed the wound antiseptically and placed the patient in bed.

At an early hour the next morning I was called to see the patient, the messenger saying he was "spitting blood." I found free hemoptysis, but it readily yielded to ergotin and gallic acid. Examination of the chest showed dulness over the whole left side except at the apex, with complete flatness at the lower portion of the chest. Temperature was normal: Pulse but slightly accelerated. It was evident that the pleural cavity was partially filled with blood and that the lung had been punctured.

The patient was kept for several days on the hamostatics, during which time he occasionally spit blood. After this the bleeding entirely ceased, the dulness disappeared, the wound healed rapidly. There was no elevation of temperature during his convalescence, nor were there any abdominal symptoms, except slight tympanites, lasting for three or four days.

The patient was discharged February 17th, perfectly well.

This case is reported because of the interest attaching to penetration of both great cavities of the body, and a wound of the diaphragm, all of which healed in a very brief period, without any untoward symptom, except hemoptysis, and this was readily controlled by constitutional means.

## New Instruments.

### A CHEAP HIP-SPLINT.

BY ROBERT W. LOVETT, M.D.

ONE of the obstacles to the successful treatment of hip-joint disease in out-patient clinics has been the difficulty and expense of obtaining a suitable traction splint. In a Boston instrument-maker's catalogue the long traction splint is priced at from \$30 to \$40. Even as made in hospital instrument-shops, the price of such splints is apt to be so large that it places the treatment out of the reach of a certain class of very needy people.

At the Children's Hospital out-patient clinic, in Boston, the need of a really cheap splint has been so much felt, that various attempts have been made to find an efficient cheap substitute for the regular pattern of splint where traction is made by a windlass, a form of splint which costs from \$10 to \$12. The splint shown in the accompanying figure seems to fulfill such a requirement, and in use it has proved satisfactory. In construction it is so simple that it can be made by any blacksmith and its cost is very moderate.

At the hospital workshop it costs from \$2.50 to \$3.00 completed. An iron firm in Rome, N. Y., gave me an estimate on the expense of making the splint in quantity, using castings where now we use forged pieces, and estimates the expense as \$1.50 per splint in small quantities, or \$1.25 or less, in large numbers.

The splint is made of one-quarter inch gas pipe, or in cases where it is very long of three-eighths inch pipe. The upper end of the pipe is forged out flat to be riveted to the pelvic band A B, which consists of a flat steel band about an inch wide, shaped to fit the curve of the pelvis. Buckles are to be attached to this at suitable places, in front and behind, for the perineal bands, and at the ends of the arms to secure the splint in place by means of a strap around the other side of the pelvis. The pelvic band is set upon the upright at an angle with the anterior arm lower than the posterior.

The gas-pipe upright terminates below in a flat forged foot-piece. This foot-piece is forged out of common steel with its upper end small enough to go inside the gas-pipe, which is cut off squarely. The whole is heated and welded together at a point four

or five inches from the bottom of the foot-piece. The foot-piece is shod underneath with a thickness of sole leather and pierced for the rivets to fasten two half-inch leather straps (F) by means of which traction is to be made. A coupling is inserted at D to provide for the lengthening of the splint as the child grows. It is more convenient to have two couplings in the upright so that the length of the splint may be changed by the insertion of a piece of pipe of varying length between them.

The semicircular arms C and E are forged out of flat malleable iron and fastened to the upright by a small screw as shown in the detail drawing E'. Rivets at each end attach a strap and buckle to encircle and steady the leg.

The splint can be used either as a walking splint with a high shoe on the other foot, or as a traction splint pure and simple, by means of the use of crutches, not allowing the splint to touch the ground. Stout buckles with tongues should be attached to the lower ends of the adhesive plaster leg extension and the strap F buckled into them. This form of traction is of course inferior to the steadily and easily graduated pull which one obtains by a windlass or a ratchet extension, but it seems enough for all practical purposes in the hands of reasonably careful people, and it is hoped that the cheapness and simplicity of the splint may commend it in instances where simplicity and cheapness are essential.

#### AN APPARATUS FOR THE CORRECTION OF TALIPES EQUINO VARUS.

BY JOHN DANE,

*House Surgeon of the House of the Good Samaritan.*

The following is a description of a piece of apparatus which has been found useful in correcting talipes equino varus without tenotomy; and in maintaining the foot in an over-corrected position after the operation. It is a modification of the snow-shoe method, which consists of a shingle, long enough to project beyond the toes for two or three inches, strapped to the sole of the foot, with a side arm running outwards at right angles to the foot. The heel is held firmly to the shingle by means of bandages and adhesive-plaster straps running up the leg. The long projecting end of the shingle in front furnishes a lever by which to flex the foot. The flexion is obtained by means of tightening a strap; the upper end of which is put through a buckle fastened to the shin by adhesive plaster, and the lower end fastened to the front end of the shingle. Eversion of the foot is accomplished by a similar strap, extending from the end of the side arm to the middle of the leg.

The apparatus described here consists of a light frame, which replaces the plaster around the leg, and furnishes a basis for flexing the foot without obstructing the circulation of the leg, as often happens with the method just described. It consists of three uprights connected by two semicircular posterior steel bands. Each of the calf bands is furnished with a strap and buckle. The two side uprights have each two eyelets riveted to their sides; the posterior upright has but a single eyelet placed behind. The two buckles, which are to receive the straps that come from the toe and arm of the shingle, are sewed to the side of a piece of webbing of about eighteen inches in

length. They should be side by side, and less than two inches from one end of the strip. To this end is also sewed another buckle, by which the strip can be buckled to itself. Furnished with its buckles, the long webbing is applied to the leg in the form of a figure-of-eight, passing through the several eyelets, as shown in the cut. This will bring the two buckles in front over the shin. Through these are passed the straps from the shingle and its arm. By tightening on these straps flexion and eversion may be obtained to any desired amount. The pressure will be so much distributed that it will not impede the venous circulation. Finally, the whole frame is not pulled down by the tension of the straps; for the more strain brought by them on the buckles, the tighter will it cause the webbing to which they are attached to grip the limb. The simplicity of this apparatus and its ready application are much in its favor.

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

ANNUAL Meeting, Monday, January 12, 1891, Dr. W. L. RICHARDSON in the chair.

#### ORAL COMMUNICATIONS.

##### PATHOLOGY OF HYSTERICAL JOINT DISEASE.

DR. MORTON PRINCE: I have here a case that I think of considerable interest, and also of practical importance, because it seems to me to throw light on the nature and pathology of so-called hysterical joint diseases. There is nothing very remarkable about the case in other respects.

This little girl I showed a year ago at a meeting of the Society for Medical Observation. She was then in just about the same condition that she is now. I had not seen her from that time until a short time ago when she presented the picture that you see. It has been quite puzzling to make out what was the real nature of the trouble. You will see that there is very decided atrophy of the muscles of the right leg and thigh. There is a contracture of the hamstring muscles, and in consequence the leg is held in a position of semiflexion. There has been pain in the knee-joint, but there is none now. There is a certain amount of deformity of the pelvis and the body due to an attempt to counterbalance the deformity of the leg. When I first saw her she walked on the ball of her foot, but she now plants the foot squarely on the ground. I have never been able to straighten the leg completely. She has been repeatedly examined by Dr. Burrell, Dr. Cushing and myself. No one has been able to detect any disease of the hip or knee joint, and yet she has not improved beyond what she did during the first few months, though she is much better than she was when I first saw her. Although the disability has been recognized as hysterical, it has been very difficult to understand the mechanism of the trouble. I think I have at last hit upon the true solution of the difficulty. Any attempt to straighten the leg has always resulted in severe spasm of the hamstring muscles. There is quite marked atrophy of the muscles of the leg and of the thigh muscles so that it measures one inch less at this height than its

fellow. There is also atrophy of the calf. There are no electrical changes in the muscles. We have then to explain here contracture of the ham-string muscles, atrophy, pain about the joint and the tilting of the pelvis, apparent lordosis, and possible a little paresis of the extensor muscles. The other day when I was examining her, and when I tried to make her straighten her leg by her own volition, I noticed that there was no hardening of the extensor muscles. Nor did the tendon and patella rise in relief as they should. She was able to extend the leg with considerable vigor up to a certain point, namely, until it was in the position in which it was habitually held, but the minute it reached this position, although she apparently made strong volitional efforts, the extensor muscles of a sudden ceased to contract, while the ham-string muscles were thrown into strong contraction. This at first sight would seem to indicate a paralysis of the rectus muscle. But when she was told to run and to step upon a chair, she could do either with ease, so that there cannot be any paralysis of that muscle, and the electrical reactions are normal. There is rather a sudden inhibition of that muscle when she attempts to straighten the leg. She seems to have lost volitional control over it. When I told her to contract the extensor muscles and draw the patella up, she was not at first able to do it, but by persistent effort I finally succeeded in getting her to volitionally accomplish this, and then, for the first time, the flexor spasm abated and the leg became straight. Although there is great apparent atrophy of the right leg, really it is not true, because the measurements show that the right leg measures the same to-day as a year ago, but the left leg has grown while the right leg has not. There may originally have been some atrophy of the leg, but that ceased to progress. The other leg developed but the growth of this remained stationary.

The question arises how to explain these symptoms. The treatment since this discovery has been to induce her every day to pull up volitionally the patella tendon. During this exercise she straightens the leg. The explanation which I offer is this: It is what I call an association neurosis. Her present condition originated one and a half years ago, when she fell off a chair and sprained her knee. Originally she hurt the joint, and the consequence was that every time she bent the knee, there was pain with spasm of the muscles moving the joint. Whenever she moved her knee there was pain. The painful centripetal impulse was sent to the sensory centres and from thence an impulse was reflected to the motor muscles, and the result was spasm. Whenever there was pain on moving the leg there was inhibition of one set of muscles and contracture of the other. This is the normal physiological process. That went on a long while, but finally these processes became so firmly associated that whenever the leg was moved inhibition of one set of muscles and spasm of the other was induced. The various centres became united together by the reflex process, so that every centripetal impression from the knee, whether painful or not, excited the process. The injury to the knee was finally recovered from, but now the association neurosis is so firmly established that the normal sensory stimuli (of motion) cause both inhibition and spasm.

I have seen the same thing in a man who had injured the ball of his toe and in consequence always walked holding his toe bent up. After doing this a

great many years it came about that whenever he drew his toes up into this position they immediately became "set," and were held in that position rigidly and beyond his control. You could move them above or below the place, but when they approached it spasm took place, and they became rigid. In this girl you can extend the knee so far, but when you reach this point, spasm comes on from association neurosis. Of course, calling such cases hysterical joints is no explanation at all. What we want to know is the mechanism of it.

In regard to the atrophy I think that probably the same inhibitory action that paralyzes the extensor muscles acts on the anterior cells of the spinal cord and retards the growth of the leg. This is the best explanation I can offer.

DR. STURGIS reported

#### A CASE OF SLOUGH OF THE LIP IN A DIABETIC PATIENT.

On December 14th last I was called to see a gentleman, sixty-four years of age, who had what he thought was a large cold-sore on his lip. The right upper lip was much swollen, and this swelling extended to the malar bone above. There was a slough forming on the lower border of the lip. I at once called Dr. M. H. Richardson in consultation. The slough began to separate on the following day, disclosing behind it a pocket about half an inch deep and very nearly the same measurement across. The lip was now very hard and brawny and of a dusky color.

On the 16th another opening formed on the inner aspect of the lip. This opening was caused, I think, by pressure from the lower canine tooth on that side. On the 23d, or ten days since the first appearance of the disturbance, both openings had closed and the lip had returned to nearly its normal appearance. Treatment consisted in keeping the abscess well washed out with corrosive, 1-6000, and removing all shreds four times daily.

The case is interesting for three reasons: (1) The patient had been a diabetic for seven years. When he came under my care in October, the sugar was 5.8%, on November 24th, 3.35%. The urine examined after healing of the abscess contained 2.40%, showing that the morbid process in the lip had caused the sugar to diminish if it had any effect in any way.

(2) The extraordinary rapidity with which the slough separated and the abscess cavity healed. In diabetes formation of sloughs is very common, but their separation and subsequent healing of the abscess is, as a rule, exceedingly slow.

(3) At no time during the course of the abscess was there any pain, fever or other constitutional disturbance. Sleep was good, and the appetite fair throughout. The patient told me that for three years past he had had no appreciable secretion of saliva. During the course of the inflammation there was an abundant flow, and since the healing the amount of saliva has been normal. So it would seem that an abscess on the lip, which in diabetes is prone to run to a fatal termination, in this case has left the patient in better general health than before.

Dr. J. HOMANS read a paper on

#### THE TREATMENT OF UTERINE FIBROIDS BY ELECTROLYSIS À L'APOSTOLI.<sup>1</sup>

Dr. W. H. BAKER: I think the Society is to be

<sup>1</sup> See page 249 of the Journal.

congratulated upon the very full manner in which the subject has been presented. Certainly no one can doubt the great care that has been taken, not only in the application of the electricity by Dr. Homans, but also in the following out of the records of the cases.

The main question, as I understand from Dr. Homans's paper, that would properly come before us is this: Is the treatment of fibroids by electrolysis of sufficient relief to the patient to warrant its continuance, and if so, what degree of permanency can we expect to follow this treatment? I cannot go to the extent that some have done — as perhaps Dr. Apostoli himself — that all cases of fibroids may be relieved or cured by electrolysis. I have found an exceptional case, as Dr. Homans very well knows, that will require even after treatment by electrolysis, hysterectomy. He has been kind enough to perform that operation upon such a patient of mine. But I have found in my experience certainly more encouragement than Dr. Homans has seemed to do. It is true that the number of cases that I have had in the time covered by that of Dr. Homans's paper are not as many. I reported my work by this method some four years ago before the American Gynaecological Society, and the result at that time was fourteen cases treated, in one of which there was an entire disappearance of the growth. In twelve there was a diminution in the size from one-third to one-half. One of the twelve, however, has since started up and grown again to my knowledge. The fourteenth case was unaffected by electrolysis.

My method of applying electrolysis was not altogether such as Dr. Homans has described as Dr. Apostoli's method; for I used the electro-puncture applying both needles into the substance of the growth. I was led to apply it in this manner as far back as 1876 or 1877, from an article that appeared in the *Boston Medical and Surgical Journal* at that time by Dr. Cutter, and feeling then that I was not an expert in the use of the electrical arrangement or battery, I asked Dr. Webber to manipulate the battery, and I inserted the needles. I did not see fit to use the needles that were then being used. The original needle as used at that time was similar to that which I show here. I felt that the use of such a formidable looking instrument as that was hardly necessary. The battery too, which was used by Drs. Kimball and Cutter was at fault in that it gave too much thermic action, and was deficient in intensity of current. I, therefore, had Messrs. Codman and Shurtleff procure needles which I now show you, and which, although an improvement on Dr. Cutter's, yet are not perfect by any means. They are steel needles japanned to within an inch of the end which is left exposed, a flat, cool cutting edge which is gold plated. The fact of this is that under the influence of the galvanic current, a portion of the japanning may sometimes be burned off and thereby a portion of the wound through the abdominal parietes become cauterized. The accident has occurred to me in a few instances, and although I have no deaths to report from any of my applications, yet in two instances there was a slight attack of peritonitis. The patients in which case, however, made a good recovery.

The instrument now already referred to, procured for me the other needles which I now show you, and use with perfect satisfaction. They have

the same steel tips with hard rubber coating over the great length of the needle. For a battery I use a McIntosh, a Fleming & Talbot or Waite & Bartlett. When Dr. Apostoli speaks of using electro-puncture, he uses quite a different needle; one with a very small amount exposed, a very fine needle. He introduces it not over a centimetre perhaps, and usually only one needle is inserted, and usually through the vagina into the substance of the growth in cases, where, as Dr. Homans says, it is difficult to introduce the platinum sound. In order to ascertain exactly what Dr. Apostoli's method was of applying electricity, when he was here some three years ago, I asked him to demonstrate to the Staff and a few others at the Free Hospital his method in these cases, which he did. I have since found that his method is best suited to a certain class of cases, namely, multiple fibroids, for the use of electro-puncture in my experience has been most successful where there were one, two or three large lobes, one treatment by the insertion of the negative and positive needles directly into one lobe and at another time into another lobe; but the advantage it seems to me of this method, for it certainly has seemed in my hands to be much safer than the method as described by Dr. Homans, is that it requires very many less treatments. The needles can be applied for a period of fifteen minutes, and I think the strength of the current that is needed is much less. When I published these cases four years ago I had used the McIntosh battery in perhaps an empirical way. I had been governed entirely by the strength of the pulse of the patient, and not measured by the galvanometer. Since that time I have used the galvanometer, and have tested it many times in the same way by the strength of the pulse in order to see how strong I could make the current without affecting the pulse. I have found that from seventy-five to one hundred milliamperes was as strong a current as I could use. That perhaps was equal to more than that described by Dr. Homans, because with the needles inserted into the mass there is not the great resistance offered by the walls of the abdominal parietes. The current is passed directly into the substance of the fibroid itself. But by the method as Dr. Homans has described it, I have seldom been able to carry it above one hundred and twenty-five milliamperes. But I know there are certain cases that will not yield to this method, in my experience, however, the greater proportion of them do. I remember one case distinctly in which after failing by the application of electrolysis, I sought to bring about the menopause by the removal of the uterine appendages. That failed to accomplish it however. She went on menstruating after the removal of the appendages for some time with perfect regularity, but after a year she began to occasionally skip a month, and then in that next year the use of electrolysis again applied just as before, resulted in relieving her from suffering, and also in a decided diminution in the size of the tumor.

In some of Dr. Homans's cases the question arose as to whether it was the menopause that did the good or the electrolysis. I think that we must remember in these cases that a patient with a fibroid is in my experience likely to have a much more prolonged menstrual life than one who has not such a growth. In a woman with a fibroid there would be increased menstrual activity, and she would go on menstruating up to fifty-two or fifty-five years of age from the result

perhaps of the existence of the fibroid; therefore we may perhaps reasonably expect that in the cases he refers to, electrolysis had a decided effect in helping to bring about that menopause at an earlier age.

Dr. Homans in his paper asks why it is that the fibroid should be so affected by the current and the other tissues of the body not affected. We know that fibroids are easily disturbed in their nutrition, that they are subject to certain diseases, which in themselves, tend to occasion their disappearance, that the electrical current perhaps is a thing that tends to so disturb its nutrition as to occasion arrest in its growth. I have seen a case like the one the doctor speaks of, where the patient felt better, even although the current was not turned on, so to speak. I well remember the case which was under the care of the late Dr. Peaslee, where the fibroid was punctured with an aspirating needle for the purpose of diagnosis. There was established a certain inflammatory process which went on some little time, and then resulted in the almost entire disappearance of the fibroid. Here was a case where the growth was certainly disturbed in its condition, and a good result followed even although there was no electricity applied. That led me to the belief that the electricity disturbs the nutrition of the growth, or that there is established by the puncture and electricity a certain interstitial inflammation of the connective tissue, which perhaps, in its cicatricial contraction so compresses the muscular fibres as to occasion their fatty degeneration and disappearance, resulting in shrinking in size of the whole mass.

My experience has been, I think, much more encouraging to me than Dr. Homans's has to him, and I certainly feel that I have gained sufficiently good results from it not only to continue it, but to advise others to make use of it in this class of cases.

Knowing that this subject was to come up at this meeting, I sent word a few days ago to the three last cases in which I applied electricity, and in my experience I have seldom found it necessary to apply it more than once, twice or three times to effect a decided improvement in the size, asking what the result had been since their first treatment seven weeks ago at the Free Hospital for Women. One of the cases had two large lobes. The patient, aged forty-six, noticed enlargement three and a half years ago. There had been severe flowing at the menstrual periods. She had great trouble from the size of the growth. I applied 100 milliamperes, slowly increasing from 60 to 100, watching the pulse. The application was made to the second lobe December 4th, by Dr. Strong. At that time 100 milliamperes were reached for twelve minutes. This patient returned home about a week after the last application. I sent word to her, but have received no answer.<sup>2</sup>

Another patient, aged forty-two, had complained of increased size for six years, had severe pain and the flowing was excessive. A current of 60 to 90 milliamperes was applied for fifteen minutes on November 18th. She was discharged December 19th. The probe in this case entered the uterine cavity nine inches. Menstruation since has been about two-thirds in amount of what it was formerly. She does not notice any difference in the amount of pain. She, herself, does not see any difference in the size, but

she is anxious to enter the hospital and have another application made.

The third case was that of a patient thirty-seven years of age, with greatly increased size; for one and one-fourth years, flow very excessive, amounting to twenty saturated napkins. The probe entered seven inches. Application November 18th; 98 milliamperes for fifteen minutes. She reports that she has decreased very much in size, and is very much encouraged after the one treatment.

I think from my experience that we can gain as much in one, two or three applications with the electro-puncture or more perhaps, than I have gained by very many applications by the other method described by Dr. Homans, although I think in case of the multiple fibroids where we cannot enter each small lobe or outgrowth of the uterus, that the Apostoli method is preferable. Where the lobes are distinct and large, I think we can accomplish a great deal more by the electro-puncture.

DR. J. R. CHADWICK: I began to employ this method of treatment six months before Dr. Homans, and ceased about the time he was beginning. Besides a few cases which received but a single application of the electricity, I treated eleven cases, the reports of which have been published.<sup>3</sup> Of these, but two showed a slight diminution of menorrhagia, and one, temporary relief of dysmenorrhea. In no other case was there any beneficial effect. In no instance did a fibroid decrease during or subsequent to treatment. In three cases metro-peritonitis was excited, one of which terminated fatally on the sixth day. In one case general septicemia set in on the day after the sixth application, terminating fatally on the twenty-sixth day from pulmonary embolism. The negative current had been applied to the uterine cavity by a blunt platinum sound, strict antiseptic precautions being employed as directed by Apostoli. To sum up, in eleven cases I had had two deaths and two narrow escapes from death, with practically no favorable effects. Of course, I could not pursue the treatment further. Since then I have had no experience in my own practice, but have been called in consultation to see two cases in which metro-peritonitis followed the treatment in the hands of other practitioners.

I. October 19, 1889, I was summoned to Waltham to see a lady under the care of Dr. A. Worcester. She was forty-one years of age; had had two children and five miscarriages; the last of these had been produced by the electric current in January, 1889, administered by an irregular practitioner of this city, who had been giving the electricity by Apostoli's method three times a week for a year past. She had a fibroid of the uterus rising as high as the navel, which had not appreciably changed during that time. For two months she had had constant nausea and vomiting, and of late backache, but no pain in the tumor. On examination the tumor seemed soft and almost fluctuating on the right side. Soon after my visit there was a sudden discharge of nearly a pint of pus, which persisted subsequently for several weeks. The size of the tumor was reduced about one-half. On December 17th the fibroid was still bigger than my fist, the sound passing five and one-half inches. The nausea had ceased and she was convalescent.

II. The other case was a woman nearly fifty years

<sup>2</sup> In a letter from the physician who referred this patient to me, received a few days ago, he reports the left lobe of the tumor decidedly smaller, and the right lobe perhaps slightly diminished in size.

<sup>3</sup> Transactions of the American Gynecological Society, vol. 14, p. 130.

of age, with an enormous fibroid rising to the ribs on the left side; she was very fat, plethoric, and nervous, so that I regarded the case as very unfavorable for any electric or surgical treatment, and so advised Dr. Ruddick, her attending physician. A year and a half later, in February, 1890, she entered Dr. H. O. Marey's private hospital and there received four applications of electricity by Apostoli's method; the last was followed by fever and great tenderness of the tumor. She was removed to her home, where I saw her with Dr. Ruddick on February 20th, a few days after the last treatment. She had a temperature of 104° F., and a pulse of 140, vomiting, labored respiration and other signs indicating a most critical state. This condition gradually ameliorated, and in April she had a sudden discharge of a pint of pus, since which she has slowly recovered from the effect of the electricity without any appreciable result upon the size of the tumor. I have not seen her since May 4th.

With this added experience I see no reason for changing my opinion expressed in 1889, that "the method is a dangerous one." Its claims to diminish the bulk or even to arrest the growth of fibroids have been effectually disproved in the past two years; its beneficial effects upon inflammatory conditions of the pelvic organs are not substantiated by the facts published. The sum of evidence seems to be in favor of its claims to arrest hemorrhages from the uterine cavity, but my experience satisfies me that it is a much more dangerous means than others at my disposal. In short, its caustic action, which we never doubted, is established and may be employed; all other good effects observed may be attributed to *mental suggestion*.

DR. DAVENPORT: I have been using electricity in this form for two or three years, and on the whole, the result that I have arrived at is one of disappointment as an agent in the cure of fibroids. It certainly has not yielded in my hands the results which Dr. Apostoli claims for it. I have had no serious results, although in two cases there have been slight attacks of peritonitis, which yielded very readily to rest for a few days. I have arrested the growth of the tumor, apparently, in a few cases, and there has been a general improvement in a few other cases. I would like to show a platinum sound which I have had constructed and have used in cases where there is a tortuous canal, and in which it is impossible to insert the straight sound of Apostoli. This is on the principle of the jointed repositoir of Emmet. I have been able with this instrument to reach a number of cases which I could not with the straight sound.

DR. STROUD: There are one or two points about which I should like to say a few words. First, what is the method of Apostoli? From all I learn from the writings of the followers of the school, it now consists in puncture of the tumor through the uterus and the employment of the broad abdominal electrode, permitting, or in fact demanding, the passage of a current of high intensity for a short time. When the method was first brought prominently to the notice of the profession, puncture was not deemed essential. A probe was simply passed into the uterine canal; later there was decided puncture advocated, and today operators are found occupying positions between each of these extremes. Yet under all these varying conditions, equally good results are claimed. Again, Apostoli has upon the necessity of currents of a high intensity, applied for a short time. So-called followers of

his claim equally good results from smaller currents applied for a long time.

While I have not used the Apostoli treatment with any degree of faithfulness, I have used in some number of cases the method which Dr. Baker has so fully described that it would be useless for me to attempt to add anything. From that method certainly I have seen good results follow. There are certain ill results which I think we are apt to get; these are the formation of adhesions which give the patient a good deal of pain subsequently. I recall the first case in which I used this method in private practice. There were two large lobes, one of them about the size of a foetal head, the other one twice as large. I put both electrodes into the larger lobe. The current was from an 18-cell McIntosh battery. The current was applied for twenty minutes as strongly as could be tolerated, the pulse being carefully watched. At that time, five years ago, there was no practical galvanometer to be obtained in Boston, so I cannot give the measure of the current. At the end of twenty minutes, noticing considerable swelling in the vicinity of the positive pole, I stopped the current and took out the needles. I found that the point of the electrode was gone. There was an escape of gas and bloody fluid showing that I was inducing changes in the tissues of the abdomen. She had a pretty sharp attack of peritonitis after it, and it left adhesions which remained quite a long while. They gradually stretched, however, and disappeared, so that she suffered no longer from them. That lobe diminished almost one-half in size, the right lobe remained the same. I have never applied the current to the other lobe because she has been perfectly comfortable since. The tumor on which I operated has not grown; the other has increased a little, I think. The last two years I put her upon ergot, which she has taken with more or less regularity in pretty large doses. In two or three other cases I noticed the same formation of adhesions, due, I think, to the japan coming off from the needles.

It seems to me the strength of the current used by Dr. Homan is not so great as that used by Apostoli. I have never been able to get above 100 milliamperes with any feeling of safety.

In the treatment of these fibroids it seems to me as though many of the successful results were obtained perhaps in patients who did not complain of much disturbance. The other day a patient was sent to me to have something done for a tumor in the abdomen. I said: "Of what do you complain?" She said: "I feel very nervous," and that was the only complaint she had. Her physician in palpating the abdomen for another cause discovered this tumor and sent her in. That is a case in which favorable results I think would have been obtained from almost any treatment. I did not treat her at all.

It seems to me as though most of the men who had started off as enthusiastic advocates of Apostoli's treatment were now abandoning it to a certain extent. I saw a statement, which I cannot vouch for, that the son of Dr. Keith said his father had gone back to operating in a certain number of cases, and that was against his statement that he had laid down his knife forever in these cases.

DR. BURRAGE: It was my good fortune to meet Dr. Apostoli in Paris a year ago last August and follow his work in his clinic in the Rue du Jour for about two weeks, so that I had some opportunity to

learn his technique. I was very much impressed with his earnestness and the careful attention he gave every case. I was also very much impressed with the great care he gave to the antiseptic details. He not only gave each case a douche of corrosive before treatment and one afterwards, but he kept his electrodes in boiling water between the treatments. He then dipped the electrodes in iodoform and ether before applying them. The thoroughness of his methods and the carefulness with which he carried them out commended themselves to me, and I thought if I had the opportunity I should put them into effect here in Boston. I have had a clinic at the Free Hospital since last October. I have treated about twenty cases there; and have made about ninety-two applications of electricity. It is too soon to offer results yet.

As regards the difficulty of applying Dr. Apostoli's treatment, I don't think it is as great as Dr. Homans seems to regard it. As to the expense of the apparatus I have had a battery of forty Leclanché cells put in my office at an expense of \$30, and I have rather a cheap rheostat which I had made after one of Dr. Keith's, of London, that cost a matter of \$6.

As regards the abdominal plate of clay, this is very dirty and bothersome sometimes. There is one now made with a rubber covering, and which need not be specially prepared each time. It seems to me it serves the purpose as well as one that is made up fresh. In cases where there is not very much intensity needed, I think the punk plate devised by Dr. Baker serves the purpose very well indeed.

I have here one of Gaiffe's latest galvanometers which has some advantages, and I would like to show it. It will work either lying flat or standing up, and the needle always comes back to the zero point when there is no current passing through. It is not affected by the proximity of metals.

I show you a rheostat such as I have referred to. It has two platinum points and the sliding rod is insulated by a glass tube. A weak solution of copper sulphate is used. The instrument is rather small and can be carried about easily. With a battery of forty cells, a rheostat of this sort, an abdominal plate and one or two electrodes, a man can apply electricity after Apostoli's methods very handily.

The abdominal plate shown here is one devised by Dr. Augustin Joelet, of New York. The clay is kept moist by the rubber backing. By covering the face of it with a piece of rubber sheeting, it may be kept ready for use for any length of time.

DR. KNAPP: When Dr. Homans kindly asked me to assist him in the electrical part of this work there was a good deal of experimental work that we had to do. In the first place, Apostoli gave details as to his instruments, and mentioned the strength of current used; but beyond that I believe he did not go. The question as to the number of cells to be used and the strength of the battery was more or less undetermined. About the time that we began work there was a sharp controversy going on in the *British Medical Journal* between Lawson Tait and Skene Keith as to the resistance of the body, Mr. Tait arguing that the resistance was 2,000 or 3,000 ohms, and Mr. Keith that it was 500 ohms. I knew *a priori* that the resistance must be below that of the ordinary resistance of the body, 2,000 or 3,000 ohms, because we had only one surface of epidermis to deal with, and the other electrode was against a mucous membrane, with a comparatively

vascular region to pass through. By Ohm's law it became simply a question of mathematics, with the intensity of the current equal to the electro-motor force divided by the resistance. We knew the intensity we wanted, — 200 milliamperes; We knew roughly the resistance, — 500 ohms; and that left an electro-motive force of 100 volts we had to get. There was also the question of the internal resistance of the battery, perhaps 100 ohms, and a little more allowance to be made for the resistance of our apparatus; hence, in order to make things tolerably certain, I told Dr. Homans we better have a battery which would give us an electro-motive force of about 150 volts, which we got, but that proved altogether stronger than was necessary. In point of fact I do not believe that the resistance of the body, taken from a point inside the uterus to the abdominal wall is anything like 500 ohms. That, of course, we could tell only by experiment. Still given a battery which was sufficient to furnish as much electricity as we wanted, it made no difference whether it was a battery that gave a current of 100 volts or 10,000 volts as long as we had some method of regulating it, could turn the current on and off, and had an accurate measure. Control of the current we succeeded in procuring by means of the Bailey current regulator, which enabled us to regulate the current easily and to interpose as much resistance as we wanted.

The instruments I had made with considerable care as nearly as possible like the models figured in Carlet's book. We had to make certain modifications in minor details for the convenience of inserting them into the uterus. At that time Apostoli was preaching that you could take a steel sharp-pointed instrument with a diameter of about two milliamperes, and put it into the uterus when you could not get a platinum sound into the uterine canal, and bore a new canal — a method of treatment which he has since utterly abandoned. I may say as far as electrical apparatus goes, that we had it carefully tested by Professor Holman, of the Institute. We got an Edelmann galvanometer. That has been denounced by Apostoli as thoroughly inaccurate. I believe it to be thoroughly accurate. The Gaiffe is the one Apostoli recognizes, and I have found those I have had tested to be inaccurate. In the last three years I have had four Edelmann galvanometers at one time and another. I have had three tested by Professor Holman, and they have all been exceedingly accurate. About a year ago I made some remarks upon this subject, giving comparative figures, which were published in the *Boston Medical and Surgical Journal*. I have since then visited Edelmann and bought another galvanometer of him, and I feel convinced that he is a thoroughly scientific man. We tried to follow Apostoli's directions as absolutely and thoroughly as possible. We measured our electricity by the most accurate instrument I know of. Of course, a part of our work was experimental.

DR. J. HOMANS in closing, said: I am very glad to hear Dr. Burrage speak because he seems to have had some experience with the Apostoli method. I have had no experience with Dr. Baker's method, and I should be a little afraid to try it. In Apostoli's method you have high dosage and accurate measurements. I don't know how it is with Dr. Burrage, but to me it is extremely tiresome and unsatisfactory sitting before patients for six or eight hours, putting in a sound and then douching, etc., unless it is going

to do good. If it will do good and do away with hysterectomy, I should be delighted. But I have not had encouragement enough. If I felt as sure of the good effects of the Apostoli method as Dr. Baker does of his own, I should certainly go on with it. It seems as if Dr. Baker's method was better than Apostoli's, and really accurate and efficient. But, as I have said, I am afraid to try it. Septicæmia, I suppose, ought to be charged to the surgeon, and Apostoli would say so. He has had one or two deaths himself from septicæmia. But when under this treatment these tumors do not diminish in size, and the hemorrhage does not cease, then the advocates of the method say: "You must keep on. Twenty-five treatments are too few. You must keep on two years." I am afraid, in fact I am certain, that I have not the patience to follow out the method without more beneficial results than I have seen.

#### THE NEW YORK ACADEMY OF MEDICINE. SECTION ON GENERAL MEDICINE.

STATED MEETING, February 17, 1891, DR. FRANCIS DELAFIELD, Chairman.

DR. JOHN BLAKE WHITE read a paper on

#### THE VALUE OF SUBCUTANEOUS ADMINISTRATION OF GOLD AND MANGANESE IN THE TREATMENT OF TUBERCULOSIS.

The discoveries of Koch within the last decade, he said, had indeed opened up a new era in therapeutics, and the future practice of medicine, it would seem, must in a great measure be conducted by the administration of remedies through that long neglected avenue, the skin. In view of the light that had been also shed upon scrofulosis and tuberculosis by Virchow, Strampell, Friedlander and other authorities, he submitted that the only true and direct route by which we might expect to antagonize such maladies must be through the skin, and thus immediately into the avenues of the absorbent system. When we desired to secure active and speedy effect from a remedy we had recourse to the hypodermic method, and it could not but be admitted that remedies introduced by the mouth to antagonize diseases originating in the glandular system are subjected to great dilution and chemical change in their course before they reach the seat of lesion, to expect the advantage that surely would accrue if they were introduced more directly into the circulation by the subcutaneous route. The pains of an individual might well be spared the incongruous and often tedious upon it of distributing and assimilating gold, in addition to the nourishment required for the support of the body. Functional incapacity of the organs of digestion and assimilation was the first condition to be removed in cases of tubercular invasion; which was removed by absorption of the adipose tissue and by anæmic atrophy.

There was an incubated period preceding the development of tubercle, in which the blood became impregnated through faulty digestion and assimilation; and the observation of Bennett, of Edinburgh, and others, tended to prove that treatment simply aimed at securing good assimilation of food, not infrequently caused the tubercular process and causes the complete disappearance of all general symptoms. The first and necessary condition in the treatment of tuberculosis, then appeared to be an attempt to re-establish

functional activity of the organs most directly concerned in the nutrition. For years past pulmonary tuberculosis had been successfully treated by judicious administration of medicines and the institution of hygienic measures in the incipient stages. Cases had also been recorded of well-advanced tubercular processes which had yielded to simple methods of treatment. To produce a physical condition not favorable to the deposition of tubercular tissue, and therefore inimical to the intrusion and germination of microbic life, had been the ordinary course of treatment long before the bacillus was discovered by Koch. The same line of treatment was even now advised by Koch himself, the object of whose new method was to leave a condition of tissue vitality which proves an efficient barrier to bacterial invasion. This must be due not only to selective action of the lymph itself, but to some somatic change effected through the agency of some of its elements, which results in a restoration of functional activity, followed by an improvement in general nutrition.

We had in the materia medica remedies that had long been known to possess this particular power; but none in so direct and potent a degree as the preparations of gold, which, through no fault of their own, had long since fallen into disuse. The precise action of these preparations was not yet fully determined, but there was ample reason for the belief that they exert a remarkable influence upon the general nutrition. Having given the opinions and experience of a large number of authorities with regard to their action, and stated that all these authorities concurred in stating that the remedy, so potent for ill when pushed to toxic effect, exhibits rare entropic virtues when administered in strictly therapeutic doses, Dr. White went on to say that Bartholow, while greatly extolling the efficacy of the gold preparations in cancer, scrofula, constitutional syphilis and chronic Bright's disease, advanced the important observation that they are singularly apt to undergo decomposition in the alimentary canal, a part only being absorbed as an oxide in combination with albumen. This fact, he said, would explain in many instances the inefficacy of the remedy when used internally, and was the strongest plea that could be urged for the more direct or hypodermic method of obtaining its effects in the system. Dr. White has met with one individual, a female, who manifested a peculiar idiosyncrasy against tolerance of the chloride of gold, her pulse and temperature falling below normal four hours after the hypodermic administration of a minimum dose, and the depression continuing for two or three days. Curiously enough, however, the same symptoms resulted in this patient after an injection of Koch's lymph.

He believed that the value of gold as a therapeutic agent, especially in phthisis, was enhanced by the addition of the iodide of manganese. This agent was itself an influential tonic and anti-anæmic, and had long and justly been regarded as on a par with, if not superior to the preparations of iron. It was an element ever present in the blood, as well as in the other fluids and solids of the body, and was certainly better tolerated than iron when given to remedy the persistent anæmia of tuberculosis. Under the influence of these combined salts the very action which Garrod hoped to achieve by the salts of potash seemed to be singularly secured, namely: "a ready metamorphosis of the less vital tissues, less vital deposits, less vital

plasma, and, of course, of the deposition forming the glandular and other swellings of scrofula." The effects obtained in his own experience by the hypodermic use of gold and manganese combined had been first exhilarant, followed by an increase in animal heat and vital activity. The pulse became more full and active, the temperature rose, and a decided period of reaction was established. During this period a feeling of constriction about the chest was sometimes complained of. Sooner or later there followed depression, more or less marked, but this never lasted long. These phenomena were commonly succeeded by the more permanent tonic and alterative effects, manifested by a remarkable increase in appetite and weight, with marked amelioration of the various morbid symptoms.

In addition to phthisis he had found the hypodermic use of these salts very efficacious in chronic glandular enlargements and sinuous abscesses due to scrofula, chronic obstinate skin affections, especially of a leprosy character, persistent anaemia, chronic Bright's disease, and the cachexias due to syphilis and scrofula.

DR. WHITE gave the following directions for the use of the fluid he employs: Take from five to ten minims of a one per cent. solution of carbolic acid and boil it in a test tube. (This step is unnecessary if a one per cent. solution of carbolic acid is prepared with distilled water.) When thoroughly cooled add one or two drops of the solution of gold and manganese (the dose intended for injection), and when well mixed, charge the syringe for use. The patient's temperature should be carefully recorded every three or four hours, and no dose should be repeated until the reactionary effects of the previous dose have subsided. It is also suggested that the temperature should be noted every four hours for several days before treatment is commenced. The initial dose should never exceed one drop for an adult. In combining the chloride of gold with the iodide of manganese, unless some special skill is exercised, a precipitate always results, which is liable to render the liquid useless. When correctly compounded it should have no precipitate, and present a rich garnet color. After the initial doses of one drop the dose may be increased to three drops, provided no intense reaction has been produced.

Dr. White then related in detail the histories of three cases of phthisis, as examples, which had been under treatment since December, and in which marked improvement had occurred. One of the patients had gained about eight pounds in weight. The expectation in some of his cases, he went on to say, had diminished very remarkably—in one instance from fourteen ounces to two ounces in the twenty-four hours. One of the features of greatest interest was the rapid gain in body weight, following improvement in the appetite and the functions of digestion and assimilation. The improvement in respiration was not so immediately apparent, but in time the respiration was clearer and there were fewer rales, and less pronounced dulness over the affected areas. It was his desire to avoid severe reactions as much as possible, as he believed that the best therapeutic results would follow from moderate doses producing no very decided reactionary effects.

DR. J. R. LEAMING said, that he welcomed all honest efforts in this field. We are still waiting for more light, and we certainly needed all that we could get.

DR. S. H. DESSAN said that he had seen some of Dr. White's cases, and from one of them particularly he had had the personal testimony of very decided improvement in a short space of time. The method advocated by Dr. White had excited much attention in another Society to which both Dr. White and himself belonged, and all its members were watching with much interest for the report of further results. It was only fair, it seemed to him, that the plan should be given a trial for a sufficient length of time to enable one to form some estimate of its real value.

DR. HENRY S. NORRIS said, that while he was on the same service at Charity Hospital as Dr. White, and had seen most of his cases, he had had the opportunity of trying this treatment in only one case himself, and that was one which was not at all well suited for injections in any way. The patient was a female, and on January 7th he made the first injection with one drop of a two per cent. solution of chloride of gold and iodide of manganese. The only improvement that he had noticed was a slight gain in weight, and when he made an examination of the patient's chest to-day he found that the disease had apparently involved more of the lung tissue than previously. Still, she stated that she felt better, and that both cough and expectoration had diminished. The conditions under which the woman was living were so unfavorable, however, as to make her case a very unsatisfactory one in which to make trial of the method. In Dr. White's cases he had personally noted the general improvement which had been described in the paper.

DR. GRINNELL said that while he was more familiar with the Koch treatment than with Dr. White's, he had had some experience with the latter. Up to the present time, however, he had not been impressed with the great value of either one of these methods, though it was, of course, desirable to have a more extended series of observations before arriving at any definite conclusions.

The CHAIRMAN said, that we seemed to be still as much in the tentative stage of the treatment of tuberculosis as ever. He was, therefore, always glad to hear of conscientious work in any new direction; and he trusted that the method advocated to-night might be thoroughly tested.

DR. W. C. JARVIS said, that he could vouch for the remarkable manifestations in the way of reaction after the gold and manganese injections mentioned by Dr. White. This reaction closely resembled that observed when the Koch method was used, and it was the opinion of the House staff at Charity Hospital that it was difficult to distinguish between the two. The improvement in some of Dr. White's cases was marked, and the effects of the treatment, he believed, were not in any way excelled by those of the Koch method.

DR. WHITE, in closing the discussion, said that the treatment described he advocated not as a specific, but as an adjuvant to other treatment. In connection with this remedy, however, he believed that either treatment would be found to be more advantageous. Up to the present time he had seen no bad effects whatever from the use of his injections, and there had been no case of abscess, or any serious local irritation resulting from them, although some of the patients had received as many as twenty-eight or thirty injections.

DR. JAMES R. LEAMING read a paper on

**COUGH: ITS USES, SIGNIFICANCE, AND INDICATIONS.**

The most obvious use of cough, he said, was expulsion of mucus through the air passages. Equally important, though not so obvious, was its service in causing expansion of the lungs. These two necessary conditions of health were maintained by this complicated automatic cough machine, with which we also breathed. A deep inspiration was immediately followed by rigid contraction of the larynx to prevent the escape of the inspired air; and at the same time the diaphragm and intercostal muscles contracted with all their power, secondarily assisted by the rigid contraction of the muscles of the abdomen and the perineum. At the supreme moment, when the contained air was most compressed, the muscles of the larynx gave way, and the tidal air was shot out, as from a gun barrel, forcing out with it mucus, blood, or other foreign matter, producing the sound which gave it its name—cough.

Two sources of stimulation excited this act: *first*, that within the tidal air-tract; *second*, that within the pleura. The tidal air-tract was that part of the upper air passages traversed by the air in respiration, and it was characterized by cartilage within the fibrous bronchial sheaths and the absence of alveoli. The true respiratory system was characterized by the absence of cartilage within its passages and by the presence of alveoli, and it was constantly distended by residual air, which was a barrier to the passage of inspired air in a body. Mucus, and in a degree pus and blood, occurring in the true respiratory system, were raised upward by the ciliary movement peculiar to the mucous membrane of this locality, until, reaching the tidal air, it was caught up and rushed out with an explosion. While this process of raising and expelling the mucus was constantly going on in the upper air passages, at the same time, and by the same act the residual air confined within the distensible true respiratory system was forced by the diaphragm upward against the lungs. The structure of the lungs presented a system allowing great expansion without injury during the violent and repeated assaults of the diaphragm.

The residual air was filled with poisonous elements in gaseous form, derived from the venous blood, but, through the interchange of oxygen and carbon, purification as by fire took place, and the separation of the poisonous gaseous elements on either side of the true respiratory line in the alveoli was maintained. Such elements, however, as could not be burned up and purified, or thrown out of the system by the natural emunctories, were extended through the pleura, and remained as a temporary deposit upon its surface. If nature was unable to remove this, and it organized into imperfect membrane, contraction immediately commenced, and the circulation in the capillaries of the periphery of the lung was in a degree shut off. It might be but the beginning of simple fibrinoid, and its disabling effect only moderate. Again, it might be more or lesschievous, of a more or less tuberculous character, and its organization upon the pleura be the beginning of active disease.

The condition upon the pleura was foreign, and the cause of cough, and excited cough while yet the circulation in the capillaries of mucus. But in time the mucus caught up in the capillaries was back-ward into the nutrient arteries of the lungs, and

congested the bronchial arteries from which they were derived, while exudation of mucus or blood in the bronchial tubes was the natural relief. This again excited cough: the cough of expulsion and the cough of expansion.

The uses of cough were not sufficiently considered, and consequently the popular demand was to stop the cough. But stopping the cough without removing the cause only increased the evil tendencies of the disease. There were other and more successful ways of managing the cough than by overpowering the system with opiates. About thirty years ago Dr. George Philip Camman wrote a paper upon the management of cavities in the lungs by posture and position, in order to empty them, and thus to gain rest and sleep without giving large quantities of medicine. This principle of securing relief by posture might be carried out with a cavity, with a few exceptions, however situated in the lung or connected with a bronchus. The cough performing its uses of expulsion or expansion should not be prevented, but rather guided so as to do its proper work without doing injury.

Whooping-cough was a self-limiting, self-protecting disease of infancy and childhood, and, if uncomplicated, formed no pathological products within the air passages. The first four weeks was called the inflammatory period, and in this the patient was to be watched to prevent inflammation and dangerous complications. The cough should be modified and controlled, but not stopped. The great use of this cough was in correcting the little disabilities which occur in infancy and childhood from colds and inflammations or where portions of the lungs remain from birth undeveloped, as in atelectasis. Then the whooping-cough became a powerful agent in expansion, and was a means of restoring the lungs to their normal state. The disease appeared to be mostly one of the pneumogastric nerve, and consequently the cough was characteristic. The irritating motive being located in the larynx, a procession of explosions ended in a long, noisy inspiration. The pneumogastric nerve performed, in addition to other and greater functions, the office of a burglar-alarm in the house of the soul, and its bell was constantly watchful. A pea put into the ear or the presence of hardened wax there might cause cough or vomiting. The cutting of a tooth might do the same. The air passages and inter-pleural surfaces were the more direct avenues, and were the most obviously useful. Worms or indigestion were heralded with a cough. The kidneys and the liver telegraphed, and announced the result with a cough. The reproductive organs had a peculiar sympathy with the par vagum, although perhaps no direct communication, unless it was through the great sympathetic.

Dr. Leaming then went on to speak of a neurotic cough which he termed the hysterical cough of chlorosis. While not a frequent form of cough or of hysteria, he believes it still occurred often enough and with peculiarities sufficient to be placed in a class. Since his attention had been directed to the matter he had seen in the *Lancet* an article on "The Barking Cough of Puberty," by Sir Andrew Clark, who had seen and studied a considerable number of cases and gave a number in detail, boys and girls. In this country we had many more such cases among girls than among boys, for there appeared to be peculiarities that were due to environments. The American boy was not like those described by Sir Andrew, and he did not

remember to have met with a single one who had the barking cough of puberty.

The concluding portion of the paper was as follows: The par vagum is a clumsy, friendly nerve. It is the source of all our friendships. We dine together, meet together, drink together, by its influence. And in an assembly of people a cough will immediately be answered by coughs through the hall. One watching, too, who knows what he hears, will recognize the short hack of pathological conditions at the apices of the lungs; or it may be spasmodic, which indicates the lower part of the chest near the diaphragm as the location of the disease; or the cough may be simply catarrhal or nervous; or he may hear the scraping of the throat, the bringing up of mucus, with a rasping noise, which is a peculiar cough, and indicates old pleuritic adhesions relieved thus by a constant flow of mucus. Sometimes you may pick out of an audience several such, but whenever you hear this sign, you may look for a thin, nervous, Cassius-like individual, who thinks too much; for the scraping of the throat, the thin, anxious, worrying individual and old adhesions go together.

### Recent Literature.

*Text-Book of Hygiene. A Comprehensive Treatise on the Principles and Practice of Preventive Medicine, from an American standpoint.* By GEORGE H. ROHÉ, M.D. Second Edition. Philadelphia and London, 1890.

In this text-book Dr. Rohé has brought together "the essential facts upon which the art of preserving health is based, and presents them to the reader in clear and easily understood language."

This second edition is much improved by the introduction of illustrations and charts. Nearly every chapter contains valuable additional material. The principal additions are in the chapters on Air, Water, and Quarantine. The latter is contributed by Surgeon W. Wyman, of the Marine-Hospital Service.

The topics treated in the different chapters are as follows: Air, Water, Food, Soil, Removal of Sewage, Habitations, Hospitals, School Hygiene, Industrial Hygiene, Military Hygiene, Naval Hygiene, Prison Hygiene, Exercise, Bathing, Clothing, Disposal of the Dead, The Germ Theory, Contagion and Infection, History of Epidemic Diseases, Disinfectants, etc., Vital Statistics, Quarantine.

Health officers, physicians and students will find the volume a trustworthy text-book upon the subjects of which it treats.

*Massage; a Primer for Nurses.* By SARAH E. POST, M.D. 12mo, pp. 51. New York: The Nightingale Publishing Co. 1890.

This little manual is made up of lectures delivered before the training school at Orange, N. J. The value of such a book, in comparison with personal instruction by actual performance of massage, is, as the author admits, very slight. Admitting the necessity of such a work this little volume seems to have fulfilled its purpose tolerably well. No one can learn massage from it, but to the nurse who already knows the principles of massage it will prove a useful guide in directing her in the application of massage to different parts of the body, and for the various ends desired.

### THE BOSTON

## Medical and Surgical Journal.

THURSDAY, MARCH 12, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DANRELL & UPHAM,  
283 WASHINGTON STREET, BOSTON, MASS.

### A CASE OF EXTENSIVE RESECTION OF THE STOMACH.

#### THE RÔLE OF THE STOMACH IN DIGESTION.

At a meeting of the Royal Society of the Physicians of Vienna, Porges recently presented a patient on whom Maydl had practised the resection of a large portion of the stomach. The patient was a man aged fifty-seven years, who had been for several years affected with gastric troubles, and who, when he entered Maydl's service, presented in the region of the stomach a hard and mobile tumor, the size of a closed fist. This tumor was a carcinoma which occupied almost the whole of the greater curvature, and involved more than half of the periphery of the stomach. Maydl resected a fragment of the stomach seventeen centimetres in length and eighteen in width. The greatly dilated condition of the stomach enabled the surgeon to effect perfect reunion of the duodenal end to the extremity of the cardia. The results of the operation were excellent; twelve days after the operation, the patient ate hashed meat, and at the end of three weeks, he left the hospital cured. His weight increased by eighteen kilogrammes and a half. Five months after the operation (the day of his presentation to the Society) the patient was well, and presented no trace of a return of the disease.

The interest of the case, according to Maydl, is centred in the fact that the resection was practised in the continuity of the stomach, without resection of the pylorus. Despite the great extent of the part excised, digestion was perfectly performed.

At the same meeting, Kahler remarked that the entire stomach had been extirpated in dogs without any sensible impairment of the digestion; this proves that the small intestine may to a great extent take the place of the stomach in the digestion of food. This fact also finds confirmation in clinical experience, for we often observe a normal digestion in individuals affected with gastric catarrh with atrophy of the pepsin glands. In fact, at a meeting of the Société de Biologie (held February 14, 1891), it was announced that Mathien

and Remond had, by their researches, arrived at the same conclusions as Heidenhain and Czerny, to wit, that the gastric mucous membrane "plays but a very secondary rôle from the point of view of digestion."

#### COLUMBIA COLLEGE AND THE COLLEGE OF PHYSICIANS AND SURGEONS OF THE CITY OF NEW YORK.

By the new arrangement made between Columbia College and the College of Physicians and Surgeons of the City of New York an old medical school is to be supplied with a handsome endowment. The Medical School becomes an integral part of Columbia, exactly as are the Law School, the School of Mines, the School of Political Science, etc. The trustees of the present Medical School go out of existence, having previously transferred to the trustees of Columbia their land, buildings, equipment, and their small endowment fund. Columbia agrees to use all that she receives from the Medical School for purposes of medical education forever; she agrees to use all gifts that may hereafter be specifically given to the Medical School for the same purpose, as well as all fees for tuition and other receipts from the Medical School.

As her first instalment from her general fund for this purpose she has agreed to spend upon the Medical School during the first year of the union or merger, one hundred and twenty thousand dollars (\$120,000), and she understands that this sum does not represent the limit of the annual budget that she will be likely to vote for medical education. This sum includes the estimated receipts from students' fees — about \$80,000.

Columbia guarantees forever to the governing faculty the right of nomination to all teaching positions in the school. The governing faculty is understood to include only the incumbents of the seven primary chairs and their adjuncts.

The agreement goes into effect on the 1st of July, 1891.

Bills are now before both houses of the State legislature authorizing the surrender of their charter by the trustees of the College of Physicians and Surgeons.

It seems probable that the establishment of these relations between Columbia College and the Medical School, which had previously been only nominally connected with the College, will lead, at an early date, to the addition of a compulsory fourth year to the medical course, under conditions ensuring permanence, and a favorable influence upon the elevation of the standard of medical education.

**STREET CLEANING IN LARGE CITIES.** — This subject will be treated in the April *Popular Science Monthly*, by General Emmons Clark, of New York. The article will include some explicit practical suggestions for the proper performance of this important work.

#### THE THERAPEUTIC VALUE OF KOCH'S REMEDY IN LUPUS VULGARIS.

An especial interest is involved in the application of Koch's tuberculin to lupus because its cutaneous situation allows its behavior under the remedy to be watched most closely. One of the chief reasons given for believing in the therapeutic value of Koch's remedy in general tuberculosis was its alleged curative effect upon lupus. The dermatologists were not the first to experiment nor the first to express an opinion as to the results obtained, but they have been studying the remedy with all the care one would naturally expect.

"The Method of Koch in a Dermatologic Point of View," is the title of two articles in successive numbers of the *Annales de Dermatologie et de Syphiligraphie*, by Dr. Georges Thibierge, which deserve special attention on the part of all interested in the remedy. In these articles the author reviews most carefully all the cases that have been reported in which the remedy has been used in dermatological cases, and he reaches some interesting conclusions, nearly as follows: The ameliorations produced in cases of lupus are incontestable, and are seen in France, England and America as well as in Germany.

In some cases there has been noticed a rapid disappearance of the accompanying infiltration, but no one has yet published a case which can be considered cured, that is to say, in which all the tubercles of lupus without exception have ceased to be apparent. The writer of the article in question even goes so far as to make the statement that he knows on good authority that the first lupus patients treated at Berlin are in an almost stationary state, and that not one among them has been relieved of all the lupus nodules even temporarily. The case which has come the nearest to recovery is that of Morris and Pringle, in which the cutaneous lesions are completely repaired, the cicatrix has become smooth, and there are no more lupus nodules to be seen. The lesions of the mucous membranes, which were very considerable before treatment have also undergone a favorable evolution; but five days after the conclusion of the treatment little nodules could be seen on the gums and the arch of the palate, and a month later it was evident that these lesions had become much more prominent, and showed signs of active increase. This case suffices to show that the lesions, which still persist at the time when the reaction after the injections of the remedy has ceased, are capable of taking on renewed activity. When tuberculous tissue persists, one must fear that the recovery is not absolute.

The conclusion reached by our author, from all the known cases, is to the effect that the method produces in certain cases of lupus a genuine and considerable amelioration; it produces rapid cicatrization of ulcerations, but it has not yet produced an apparently complete recovery, much less a recovery that one is authorized to hope will be lasting. It has, on the other hand, produced a comparatively large number of accidents more or less serious, and in two cases the

death of the patient; it leaves after its employment visceral lesions, of which it is impossible to foresee the end; it reawakens sometimes latent tuberculous lesions; so that it cannot be applied indiscriminately to all lupus patients. Under these conditions, without underestimating the high scientific and diagnostic value, without denying the therapeutic value of the remedy, it is necessary to counsel extreme prudence in its employment, which should always receive the formal consent of the patient.

This report, of which we have given but the barest conclusions, without the facts on which they are based, seems of extreme value in reaching the just appreciation of this new method of treating tuberculosis, a method from which so much was hoped. It is evident that the most sanguine views are not realized; it is equally evident that the remedy, or the method, deserves earnest but careful study at the hands of its friends, and patient waiting on the part of the interested public.

#### EFFECTS OF TUBERCULIN ON TUBERCULOUS GUINEA-PIGS.

It will be remembered that at the Berlin Congress Koch announced that he had found a remedy (meaning his fluid) which, when injected in tuberculous guinea-pigs, would arrest the disease.

Later experimenters have not witnessed the same results. Thus, Dujardin-Beaumetz, at the Cochon Hospital has inoculated guinea-pigs in advanced stages of tuberculosis with tuberculin; they rapidly succumbed. In another series of experiments he took six healthy guinea-pigs; the first two were inoculated, first with tuberculosis, then with Koch's fluid; the third and fourth were inoculated, first with tuberculin, then with tuberculous material; the last two were inoculated only with tuberculosis. All died at about the same time and with the same symptoms and lesions; in none were the symptoms made at all better by injections of tuberculin.

At a late meeting of the Academy of Medicine, Jaccoud announced similar results from an experiment of his own, which, he thought, went to prove that the antecedent impregnation of the organism by Koch's liquid does not prevent the development of tuberculosis.

#### MEDICAL NOTES.

**MEDICAL SCHOOLS IN TURKEY.**—In the Turkish empire there are five medical schools, two in Beirut and one in Constantinople, Cairo and Aintab. The school in Cairo, which has a seven years' course, gives a diploma which allows the holder to practice in Egypt only. Except for this the Constantinople school, which has a course of six years, is the only institution giving a degree with the right to practice in the empire. The other three schools are under the charge of different missionary societies, and must send their graduates to Constantinople for examination.

**A TRIBUTE TO THE MEMORY OF HENRY J. BIGELOW.**—The *Indian Medical Gazette* for February, says editorially that India is under a special debt of gratitude to this great American surgeon. "It is to Bigelow, and to him alone, that we owe the great beneficent innovation of litholapaxy, or lithotripsy at one sitting, and India, in many parts of which stone is so prevalent, promises to profit by it in a very special manner. . . . Those who have read this journal for the last ten years need not be told how great and good an invention this was." A sketch of his life is given, and of the meeting at which "orations were delivered by eminent medical men—Hodges, Wendell Holmes, Henry Lee, Cheever, and others."

**KOCHIANA.**—The legal price of Koch's fluid is twenty-five marks for five cubic centimetres, about six dollars. All dealers must return to the laboratory any of the fluid which is unsold six months after it was made, where they will receive a fresh supply in exchange. A Western paper recommends that a similar law be passed in this country in reference to butter.

It is rumored that as a ruling has been made that tuberculin is subject under the McKinley bill to a duty of twenty-five per cent., there will soon be a lymph factory started in this country, and the pauper labor of Europe will receive another severe blow.

**A NATIONAL SANITARIUM.**—Dr. W. T. Parker, of Salem, Mass., who as a United States Army Surgeon has had opportunities for studying the climate of the Southwest, in connection with pulmonary consumption, has written a letter to President Harrison, urging him to ask Congress to establish a national sanitarium for the treatment of consumption and to authorize the president to appoint a committee of three or more physicians to visit abandoned army posts in central Mexico and southeastern Colorado, select a site, and make a report within six months after their appointment. They are to receive their expenses, and a proper per diem compensation. The secretary of war is to furnish this committee at once with a list of abandoned government stations for them to select from, and the act also calls for an appropriation of \$50,000 to refit the station selected, and maintain a hospital as proposed.

**GERMAN SURGICAL CONGRESS.**—The twentieth Congress of the German Surgical Society will be held in Berlin from April 1st to the 4th, under the presidency of Professor Thiersch. The first day of the meeting will be devoted to Koch's treatment of tuberculosis, and the introductory address on this subject will be delivered by Professor von Bergmann. Patients and specimens illustrating the effects of the new method will be exhibited.

**SMALL PLATES OF GLASS.**—Assistant Secretary Spaulding has informed the surveyor of customs at Springfield that small plates of glass, with specimens of natural history attached for microscopic purposes, would seem to be entitled to free entry, when imported for cabinets or as objects of science, and not for sale.

He says such articles, if imported for sale, would be dutiable at the rate of forty-five per cent ad valorem as "glass cut," and that if imported by mail they would be subject to seizure.

#### NEW ENGLAND.

LEGISLATIVE HEARINGS, before the Committee on Public Health, of the Massachusetts Legislature, were held as follows during the week :

That unvaccinated children be allowed to attend the public schools : The petitioners in this case are those who have asked for a repeal of the law for many years past. Two hearings have been held, and as yet the petitioners have not referred to the subject of their request. There has been a violent attack on vaccination by these petitioners.

Hearing in relation to the registration of medical degrees : The committee-room was well filled. Rev. Minot J. Savage appeared for the remonstrants. Rev. Solomon Schindler spoke on what should constitute a physician. Mrs. Diaz, President of the Industrial Union; Mrs. Lake, Doctor of Divinity; "Professor" Carpenter, a "Doctor of Hypnotism"; and Mrs. Frost, of Lowell, appeared in the interests of "liberty." "Dr." Bowker, a remonstrant, said that all class legislation was forbidden by Article VII of the State Constitution. "The Harvard Medical School hasn't had a new idea since it was incorporated. Why, gentlemen, the College would 'bust' if a new idea was forced into it. Playing baseball at Harvard College is not making a doctor." Dr. Wilson appeared in favor of the bill. The methods of practice amongst uneducated physicians were elaborated. Who do you find visiting the poor? Not the quack, so-called, but the regular man who serves without pay. The quack does not visit the poor because there is no money in it. Dr. Wilson's remarks were extended over the space of more than an hour. They did not help the cause he wished to represent.

Hearings before the Committee on Public Health during the coming week : March 13th, petition for a law to prevent the manufacture or sale of confectionery containing alcohol. March 17th, concerning notices of contagious diseases. March 18th, petition that unvaccinated children be allowed to attend public schools, continued.

#### NEW YORK.

CONSOLIDATION OF ST. LUKE'S HOSPITAL AND THE HOUSE OF REST. — Since last autumn negotiations have been going on between the representatives of St. Luke's Hospital and the House of Rest for Consumptives, situated in the annexed district of the city formerly known as Tremont, in Westchester County, with a view to a consolidation of the two institutions, both of which are charities conducted under the auspices of the Episcopal Church. On February 23d such action was taken by the Trustees of St. Luke's Hospital that to bring about such a consolidation there is now only necessary favorable action by the Trustees of the House of Rest. The project of consolidation contemplates the transfer of most of the patients at the

latter to St. Luke's Hospital, and the sale or lease of the property of the House of Rest, which is very advantageously situated. The House of Rest is to retain its corporate existence as an organization to enable it to take advantage of any bequests that may be made to it; while St. Luke's is to take the title of the property, which consists of about sixty city lots, valued at \$100,000. In consideration of this transfer and the further payment to it of all subscriptions and bequests that may be received by the House of Rest, the Hospital is to maintain, especially for consumptives, forty beds at the outset, and one additional bed for each \$5,000 that may be added to the original property. In this way it is hoped that more effective work for the same expenditure of money may be done. The results already obtained by the House of Rest have been entirely satisfactory as far as benefit to patients is concerned, but the expense for the last few years has been greater than the income; and it is regarded as certain that the proposed plan will be agreed to by its Trustees. The House of Rest for Consumptives was founded in 1869. Last year 219 patients were treated, and the expenses were \$14,832, while the receipts from all sources were but \$9,907.

### Miscellany.

#### SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE International Congress of Hygiene and Demography has been held (biennially as a rule) in each of the following cities, Brussels, Paris, Turin, Geneva, The Hague and Vienna. The last of these was the Congress held in Vienna in 1887. The total number of hygienists and statisticians present from all parts of the world was over two thousand. Before the close of that Congress a Permanent International Committee was appointed to decide on time and place of meeting of the next Congress of the series. On account of the fact that it had been decided to hold a Hygienic Congress in connection with the Paris Exhibition in 1889, it was resolved that the next International Congress of the series should be held in 1891, and London was chosen as its place of meeting. The date is August 10th to 17th.

A Committee of the English Members attending the Vienna Congress was formed, to take preliminary steps to bring the matter before the public. They issued invitations to universities, colleges, public corporations, and learned societies, requesting them to name delegates to form a General Committee. The list of delegates nominated up to the present time is large, and other nominations are being received constantly.

The aim of the Congress, as stated by this Committee, is to awaken public interest in the progress of Hygiene and Demography, by which latter term is understood the study of the life conditions of communities from a statistical point of view; to afford persons interested in these subjects an opportunity of meeting, with the object of advancing their progress; and, by conferences and debates, to elucidate questions relating to hygiene, demography and public health.

An exhibition of articles of hygienic interest will be held in connection with the Congress, and excursions will be arranged to various places of especial interest to hygienists.

#### PROFESSOR LIEBREICH'S REMEDY FOR TUBERCULOSIS.

At the meeting of the Berlin Medical Society, February 25th,<sup>1</sup> Professor Liebreich gave an account of his remedy, which consists of cantharidate of potash, a combination of two-tenths of a gramme pure cantharidin and four-tenths of a gramme of potassic hydrate, in twenty cubic centimetres of water. In his opening remarks he regretted that the older methods of treating disease had been so much lost sight of; and he said that he had been led to think of cantharidin in the present connection, by the good effects observed from the prescription of cantharides in skin diseases. The specific property of cantharidin is to excite serous exudation from capillary vessels, and he argued that this effect would more readily occur if those vessels were already irritated. In applying the drug to cases of tuberculosis, he proceeded very cautiously, commencing with injections of one-fiftieth of a decimilligramme of the solution of the cantharidate of potash, and gradually increasing the dose. It was found that the expectoration was thereby increased, and that the ordinary dose required to produce substantial effect was one to two decimilligrammes. It is likely that six decimilligrammes would be the maximum amount that could be safely used. No cures have yet been effected, but Professor B. Fraenkel and Dr. Heymann have been struck with the remarkable amelioration of cases so treated, and with the absence of any untoward symptoms. The drug probably only affects the diseased tissues, and it may be applicable to other affections than tubercle.

#### TRANSMISSION OF TUBERCULOSIS BY MILK.

DAUZ, of Copenhagen, who was one of the first to point out the possibility of the transmission of tuberculosis by milk, has made a new series of experiments upon the subject.<sup>2</sup> Forty guinea-pigs had two to three cubic centimetres of milk injected into the peritoneal cavity. The milk was obtained from twenty one cows, manifestly tubercular, which had been consigned to the slaughter-houses in Copenhagen. The viscera, and particularly the teats, were carefully examined after the death of the animal. In four cases the milk proved to be virulent; thrice the beasts showed tubercular lesions more or less marked. Once the cow was attacked with visceral tuberculosis very advanced, and the breasts indicated a cicatricial contraction of an uncertain origin, which, however, did not appear to be tubercular. In one case the mammary tuberculosis was reduced to two nodules of the size of a pea: one only of the animals inoculated contracted tuberculosis. The following deductions may be drawn from the experiments; namely, that the milk is only virulent in cases where tuberculosis manifestly exists in the beast; that these lesions are far from being exceptional, but that they are often so ill-defined as to render their detection a matter of difficulty during life.

#### SULPHATE OF DUBOISINE AS A SEDATIVE AND HYPNOTIC AGENT.

DR. OSTERMAYER<sup>1</sup> has convinced himself by observations on thirty patients, subjects of various mental disorders, that sulphate of duboisine employed in hypodermic injections, is a powerful sedative and hypnotic in mental affections accompanied by excitement and insomnia. Its action appears to be analogous to that of hyosine, over which it is said to possess some advantages. In the majority of cases, a dose of one milligramme produces, after about ten minutes, a very marked sedative effect, followed, in from twenty minutes to half-an-hour, by sound sleep. In cases of great excitement, however, two to three milligrammes are needed to produce this effect. The drug, in the doses indicated, has not been known to produce untoward symptoms, and may be used with greater safety than hyosine in cardiac diseases. Besides the above use, Gubler has employed sulphate of duboisine in the night-sweats of phthisis, and M. Dujardin-Beaumetz recommends it in Basedow's disease.

#### INOCULATION BY MOSQUITOES AGAINST YELLOW FEVER.

DRS. FINLAY AND DELGADO of Havana,<sup>2</sup> have published some statistics of their practice of inoculating persons newly arrived in Cuba against yellow fever by means of mosquitoes which have been caused to contaminate themselves by stinging a yellow fever patient. These observations have been carried on for the last ten years, and, in addition to a certain number which are still incomplete, may be said to consist of fifty-two cases of mosquito inoculation which have been fully followed up. Of these, twelve experienced between the fourth and the twenty-sixth day after inoculation a mild attack of yellow fever, with or without albuminuria; twelve experienced no symptoms of yellow fever either within twenty-five days after the inoculation or during three years subsequently; twenty-four experienced no symptoms within twenty-five days, but contracted a mild attack before the end of three years, either uncomplicated by albuminuria altogether or with only a very transient appearance of it; three who had had no symptoms within twenty-five days contracted well-marked yellow fever within three years; one patient who had a mild attack in consequence of inoculation contracted a severe attack later on, which proved fatal: that is to say, that of those who had been inoculated only about eight per cent. contracted the disease in a well-marked form, with a mortality of under two per cent. In order to enable us to appreciate the significance of these figures, the authors mention that they observed sixty-five monks who from time to time arrived in Havana, where they all lived under similar conditions. Thirty-three of these were inoculated, and thirty-two were not. Only two of the inoculated contracted well-marked attacks, which, however, did not prove fatal; whereas eleven of those that had not been inoculated were severely attacked, no less than five dying. It is remarked that inoculations performed in the cold weather are not entirely trustworthy, and that they should be followed up by a repetition in the spring.

## DISINFECTION OF PRIVIES.

GERLOCZY,<sup>1</sup> experimenting with the contents of privies and latrines, finds that for the mere purpose of deodorization crude carbolic acid is quite sufficient; it has, however, not much effect as a destroyer of germs. For removal of odor and disinfection of privy contents, by far the best substance is sulphate of copper. This, when added to sewage in the strength of 1-1000, clarified it quickly, destroyed all bacteria, and rendered the fluid odorless. Neither corrosive sublimate, the sulphates of zinc or copper, nor carbolic acid, sufficed for the disinfection of dry excrement. The author, as a result of his experiments, is strongly of opinion that in sulphate of copper, "blue vitriol," we have a most valuable and cheap disinfectant, that has the additional advantage that it is not very poisonous; and in any case its bright blue color prevents a possible mistake.

## A METHOD FOR REMOVING TATTOO MARKS.

VARIOT<sup>2</sup> details the procedure which he adopts for the removal of tattoo marks. The skin is first washed with a concentrated solution of tannic acid, and is then closely punctured with a set of needles, such as tattooers use. A crayon of nitrate of silver is then thoroughly rubbed over the area, and after a moment the skin is dried off, when it will be found that the punctures are deeply blackened by the formation of the tannate of silver in the superficial layers of the skin. The cauterization is said to result in an inflammatory reaction for a couple of days, and subsequently in the formation of a crust or thin eschar, which separates spontaneously in from fourteen to eighteen days, leaving beneath it a superficial red cicatrix, which gradually loses its color, and at the end of a few months, M. Veriot states, is scarcely perceptible. He does not consider it expedient to attack at one sitting an area larger than a silver dollar, lest the inflammation should be too severe. The only dressing which he employs consists in keeping the part powdered with tannin.

## THE TREATMENT OF TETANUS BY INJECTION.

It will be remembered that Drs. Behring and Kitasato, reported some time ago that on the injection of the serum of blood of animals rendered proof against tetanus into other animals suffering from tetanus, they recovered.<sup>3</sup> No experiments in this direction had been made on the human subject. On February 14th, however, the report of such a case was presented to the Medical Society by Dr. Baginsky.<sup>4</sup> A child suffering from tetanus neonatorum was admitted into the Kaiser Friedrich Hospital, and it was determined that the experiment should be made. About one tenth of a gramme of blood serum taken from an animal, rendered proof against the disease was accordingly injected, whereupon the temperature rose to 39° C. On the following day the injection was repeated, when the temperature rose to 41° C. (105° F.). On the two following days larger injections were given, the temperature rising each time to

41° C. A transient or apparent improvement took place, but the tetanic spasms soon returned in undiminished force, and the child died. The autopsy revealed marked hyperæmia of the brain and other organs, and some patches of broncho-pneumonia, but nothing else. A report of the microscopic revelations will be published later. It was proved in this case that the disease was due to the tetanus bacillus by control experiments on another animal. Dr. Baginsky is inclined to the opinion that the failure in his case was due to overmuch caution, and that a better result might have been obtained by pushing the treatment a little more.

## ANTIPYRIN AND EXALGIN IN CHOREA.

ANTIPYRIN was first employed in the treatment of chorea by Wolner in 1887.

In a paper recently read before the Société Médicale des Hôpitaux de Paris,<sup>1</sup> Dr. Charles Legroux states the results of the treatment of chorea by antipyrin in sixty cases observed throughout their course. He found that antipyrin had a beneficial effect in two-thirds of the cases, rapidly diminishing the intensity of the disease, and shortening its duration; recurrence, however, took place in three-fifths of the cases. In the cases in which the drug failed this was found to be due in some instances to intolerance (vomiting, diarrhoea, etc.), or to cutaneous eruptions; in a few cases the drug appeared to have no effect on the disease. He found it necessary to give large doses, and to reach the maximum dose in a short time. Between the ages of six and fifteen, doses as high as three to six grammes a day were well tolerated for several weeks. Serious symptoms of poisoning were never observed, and in some cases in which an eruption or vomiting was at first noticed, when the use of the drug was resumed after a short interval these symptoms did not recur. None of the cases treated had any rheumatic symptoms, but none were of a serious character.

Dr. Moncorvo<sup>2</sup> has noted in the case of his youngest patients a remarkable tolerance towards antipyrin, ninety grains being given in a day without producing the least disagreeable symptom. The author was led recently to test the action of methylacetanilide or exalgin. At first his employment of this remedy was simply as an analgesic, and he found that he might give to his youngest patient a daily dose of four and one-half grains without any inconvenience resulting. His success with this employment of exalgin was so marked that he was led to test its value in various other nervous cases. One was that of a boy, nine years of age, of a highly nervous disposition, who for a long time had been affected with polyuria, complicated with nocturnal incontinence. In this case antipyrin had been given in the dose of forty-five grains daily, and had somewhat reduced the quantity of urine, but there had been no effect on the nocturnal incontinence. The author then administered exalgin in the dose of three grains with a still more marked reduction in the polyuria and more improvement in the nocturnal incontinence of urine. The next case was that of a child, eight years of age, of a highly nervous, inherited disposition. He presented a marked case of chorea, which was entirely cured within eighteen days of treatment with exalgin.

## PRESCRIPTIONS.

APPLICATIONS IN DIPHTHERIA.—J. Neumann,<sup>1</sup> after a purgative dose of calomel, paints the diphtheritic membrane carefully and thoroughly with the following:

R Iodine . . . . . grs. vi.  
Alcohol . . . . . ʒi. v.  
Chloroform . . . . . ʒi. ss. M.

This is repeated in six hours, the throat and nose being first sprayed and gargled with lime-water.

RESORCIN.<sup>2</sup>—This has been used by many French doctors, a common application being:

R Resorcin . . . . . ʒi. ss.  
Glycerin . . . . . ʒi. M.

Paint over the throat every hour. The air of the room should be kept saturated by means of a spray apparatus containing a watery 5% solution of resorcin.

TOBACCO.—Schwitzer<sup>3</sup> uses a solution obtained by extracting one part of tobacco juice, such as is obtained from the reservoir of a pipe, with twenty parts of alcohol. The resulting liquid, after filtering, is of red-brown color, and this is painted on the affected parts. He uses also a gargle, consisting of a 1% infusion of tobacco leaves in boiling water.

## Correspondence.

## NO MEDICAL PRACTICE LAW IN WISCONSIN AS YET.

MILWAUKEE, February 28, 1891.

MR. EDITOR:—I desire to correct a statement made in the JOURNAL for February 19th (page 196), to the effect that the Legislature of Wisconsin has passed a Medical Practice Law, etc.

The Legislature has three bills before it, each of which provides for an examining board, etc., and one bill to amend the present law. The prospect of passing either of the three requiring an examining board is very poor indeed. The one to amend the present law has a better prospect, but neither of the bills has yet been reported on by the committees, or had a hearing even.

Very truly yours,

U. O. B. WINGATE, M.D., M.M.S.S.

Clinton . . .	10,424	—	—	—	—	—	—	—
Peabody . . .	10,158	5	—	—	40.00	—	—	—

Deaths reported 2,971; under five years of age 1,145; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 435, acute lung diseases 593, consumption 322, diphtheria and croup 150, scarlet fever 65, typhoid fever 48, diarrhoeal diseases 43, measles 57, whooping-cough 28, puerperal diseases 25, cerebro-spinal meningitis 21, erysipelas 19, malarial fever 8.

From typhoid fever Chicago 19, Philadelphia 9, Lowell 5, Cincinnati and Lawrence 4 each, New York and Nashville 2 each, Brooklyn, St. Louis and Boston 1 each. From diarrhoeal diseases New York 14, Chicago 8, Philadelphia and Cincinnati 5 each, St. Louis 4, Brooklyn and Nashville 3 each, Lowell 1. From measles New York 10, Chicago 8, Washington 7, Brooklyn 6, Nashville 2, Boston, Lowell, Cambridge and Lynn 1 each. From whooping-cough New York 7, Chicago 6, Philadelphia and Brooklyn 4 each, St. Louis, Washington and Cambridge 2 each, Nashville 1. From puerperal diseases New York 18, Philadelphia and Brooklyn 2 each, Boston 1. From erysipelas New York 7, Philadelphia 4, Chicago and Brooklyn 2 each, St. Louis, Boston and Lowell 1 each. From malarial fever New York, Philadelphia and Nashville 1 each.

In the twenty-eight greater towns of England and Wales with an estimated population of 10,010,426, for the week ending February 21st, the death-rate was 21.6. Deaths reported 4,139; acute diseases of the respiratory organs (London) 524, whooping-cough 126, measles 115, diphtheria 49, scarlet fever 44, diarrhoea 27, fever 22.

The death-rates ranged from 11.5 in Nottingham to 37.7 in Halifax, Birmingham 20.7, Bradford 19.3, Leeds 21.7, Liverpool 22.7, London 20.4, Manchester 30.9, Newcastle-on-Tyne 24.6, Sheffield 18.5, Sunderland 23.7.

In Edinburgh 16.5, Glasgow 28.7, Dublin 27.3.

## DEATHS.

Died in Lawrence, Mass., March 2, 1891, Timothy Sullivan, M.D., M.M.S.S., aged fifty-eight years.

Albert G. Fenner, M.D., of Dover, N. H., died, March 3d, aged seventy-seven.

Herman W. Gedicks, M.D., of Newark, N. J., died, March 5th, aged forty-two.

Dr. Hermann Quinke, Medical Counsellor, etc., died in Berlin, February 10th, aged eighty-three.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 1, 1890, TO MARCH 9, 1891.

By direction of the Secretary of War, leave of absence for two months, on surgeon's certificate of disability, is granted Major SAMUEL HORTON, surgeon. S. O. 49, Par. 7, A. G. O., Washington, D. C., February 4, 1891.

By direction of the Secretary of War, Captain WILLIAM O. OWENS, Jr., assistant surgeon, is relieved from further duty in the Department of the Missouri, and will report in person to the commanding officer, Jefferson Barracks, Mo., for duty at that station, and by letter to the superintendent of the recruiting service. S. O. 44, Par. 2, A. G. O., Washington, February 26, 1891.

The following-named officers, having been found by Army Retiring Boards incapacitated for active service, on account of disability incident to the service, are, by direction of the President, retired from active service this date, under the provisions of section 1,251, Revised Statutes: Captain J. VICTOR DE HATINE, assistant surgeon, and Captain WILLIAM R. SPRENGER, assistant surgeon. S. O. 41, Par. 18, A. G. O., February 26, 1891.

Captain FREDERICK W. FLERY, assistant surgeon, having been examined by a board of officers, and found physically disqualified for the duties of a surgeon, with the rank of major, by reason of disability incident to the service, is, by direction of the President, retired from active service, with the rank of major, under the provisions of the act of Congress approved October 1, 1890, to date from February 24, 1891, the date from which he would have been promoted to the grade, by reason of seniority, if found qualified. S. O. 45, Par. 1, A. G. O., February 27, 1891.

By direction of the Secretary of War, Major HENRY M. CROOKS, surgeon, will report in person to the commanding officer, Fort Adams, R. I., for temporary duty at that post, until the arrival of a successor to Major SAMUEL M. HORTON, surgeon, when he will return to his proper station. S. O. 45, Par. 8, A. G. O., Washington, D. C., February 27, 1891.

The following-named officers, having been found by Army Retiring Boards incapacitated for active service, on account of disability incident to the service, are, by direction of the President, retired from active service this date, under the provisions of section 1,251, Revised Statutes: Major WILLIAM S. TREMAINE, surgeon, Major LEONARD S. LORING, surgeon. S. O. 45, Par. 19, A. G. O., Washington, D. C., February 27, 1891.

By direction of the Secretary of War, the extension of leave of absence, granted Captain WILLIAM B. DAVIS, assistant surgeon, in Special Orders No. 22, February 5, 1891, Division of the Atlantic, is further extended one month. S. O. 46, Par. 7, A. G. O., Washington, D. C., February 28, 1891.

By direction of the Secretary of War, Major HENRY LIPPINCOTT, surgeon, is relieved from duty at Fort Union, N. M., to take effect upon the final abandonment of that post, and will then proceed to Fort Adams, R. I., and report in person to the commanding officer of that post for duty as post surgeon, reporting by letter to the commanding general, Division of the Atlantic. S. O. 46, Par. 9, A. G. O., Washington, D. C., February 28, 1891.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF THE U. S. NAVY FOR THE WEEK ENDING MARCH 7, 1891.

M. L. BULL, surgeon, granted one month's sick leave.

S. G. EVANS, assistant surgeon, detached from Naval Academy, and to the "Monongahela."

A. F. PROUT, surgeon, ordered to the U. S. S. "Monongahela."

H. N. T. HARRIS, as istant surgeon, ordered for examination previous to promotion.

GEORGE M. C. FLETCHER, assistant surgeon, ordered for examination previous to promotion.

ELISHA W. ALZAI, passed assistant surgeon, ordered to the U. S. S. "Albatross."

JAMES W. NORTON, Jr., assistant surgeon, ordered to the U. S. S. "Albatross."

JOSEPH H. GARDNER, surgeon, ordered before the Retiring Board March 1, 1891.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDING FEBRUARY 2, 1891.

Dr. W. J. PERRY, assistant surgeon, relieved from duty as inspector of immigrants at port of Boston, and ordered to Marine Hospital, Boston, Mass. February 2, 1891.

PERRY, T. B., assistant surgeon. Granted leave of absence for thirty days. February 20, 1891.

GOODWIN, H. T., assistant surgeon. Relieved from duty at Cincinnati, O. Ordered to Marine Hospital, New York, N. Y. February 9, 1891.

COFER, L. E., assistant surgeon. Detailed for special duty as inspector of immigrants, port of Boston, Mass. February 10, 1891.

EAGER, J. M., assistant surgeon. Assigned to temporary duty at Cincinnati, O. February 20, 1891.

## APPOINTMENT.

EAGER, JOHN M., of Pennsylvania. Commissioned as assistant surgeon by the President. February 16, 1891.

# MEETING OF THE NATIONAL ASSOCIATION OF RAILWAY SURGEONS.

At the Kansas City meeting of the National Association of Railway Surgeons last year, it was decided to hold the next meeting at Buffalo, May 7th, 8th and 9th of this year. But, on account of the meeting of the American Medical Association being set for the same time, it has been decided to change those dates, and to hold our next meeting at Buffalo, April 30th and May 1st and 2d, to which all railway surgeons are cordially invited. To all railway surgeons sending their names and addresses to the Corresponding Secretary, a copy of the Constitution and programme will be sent. All those wishing to read papers should send in the titles of their papers without delay. For further information inquire of

A. G. GUMAER, M.D., Cor. Secretary, Buffalo, N. Y.

## AN ARMY MEDICAL BOARD.

An announcement was recently made that an Army Medical Board would be in session in New York City, during April next, for the examination of candidates for appointment in the Medical Corps of the United States Army to fill existing vacancies. At the time of that announcement, there were only five vacancies to be filled. Recent Congressional legislation has, however, permitted the retirement of certain officers, so that there are now fourteen vacancies in the grade of assistant surgeon, with the probability that the number will be increased to seventeen by the time the Examining Board begins its labors.

C. SUTHERLAND, Surgeon-General U. S. Army.

## OBITUARY. JOHN HOWELL MACKIE, M.D.

Dr. John H. Mackie, of New Bedford, died at his home, on March 4th, at the age of sixty-five. Dr. Mackie was born in Plymouth, Mass., August 24, 1826, and was the son of Dr. Andrew and Hetty A. Bradford Mackie. He studied medicine at Harvard and at the Jefferson Medical College of Philadelphia, graduating at the latter place in 1850. During the war he was for a time acting assistant surgeon in the navy, resigning in February, 1862. He later held a similar rank in the army, and has since been an enthusiastic and active member of the Loyal Legion. He was a prominent member of the Massachusetts Medical Society, and was Anniversary Chairman at the annual meeting of 1876. He has been an influential and public spirited citizen of New Bedford. He has been a member of the City Council, and chairman of the local Board of Health, and one of the Board of Examiners for Pensions.

## BOOKS AND PAMPHLETS RECEIVED.

Notes on Six Cases of Perineal Section; with Some Remarks on the Technique of the Operation. By J. William White, M.D., Professor of Clinical Surgery in the University of Pennsylvania, etc. Reprint, 1891.

Illinois State Board of Health. Seventh Report on Medical Education, Medical Colleges and the Regulation of the Practice of Medicine in the United States and Canada, 1765-1891. Medical Education and the Regulation of the Practice in Foreign Countries. By John H. Rauch, M.D., Secretary, 1891.

Neuritis of the Tibial Nerves, Requiring Amputation of Leg. On the Treatment of Piles by Injection of Carbolic Acid. Suppurating Ovarian Cyst: Ovariectomy: Recovery. Two Cases in which the Uterus was Perforated by a Curette, both Recovering. Suprapubic Lithotomy: History of One Operation. Cocaine-Spray in Epistaxis, and in Nasal Surgery Generally. An Easy Method of Plugging the Posterior Nares. By Francis L. Haynes, M.D. Reprints.

The regulations prescribed for those persons desiring to present themselves for examination will be found on page 176 of the JOURNAL of February 12, 1891.

## Original Articles.

THE OUTCOME OF PERSONAL EXPERIENCE  
IN THE APPLICATION OF HYPNOTISM AND  
HYPNOTIC SUGGESTION.<sup>1</sup>

BY HAMILTON OSGOOD, M.D., OF BOSTON.

REVIEWING my experience in the application of hypnotic suggestion, I find myself not only more fully convinced of its usefulness, but I have proved to my own satisfaction that the assertions of the leading hypnotizers of Europe, with reference to the harmlessness of this treatment, when intelligently applied, are simply the truth.

Having used this method in a large variety of cases, among them women of great delicacy of constitution and marked hysterical tendencies, not in one of them have I seen anything deleterious as a result of it. Whenever a patient has responded to therapeutic suggestions, relief has not only followed, but thus far, with two exceptions only, has been permanent. In many affections, such for example, as the neuralgias, rheumatism, gout, constipation, chronic catarrhal ailments, etc., there exists either an hereditary predisposition, or such constitutional conditions, that recurrence, under circumstances of a provoking nature, would not be more surprising after relief by hypnotic suggestion, than after relief by the stereotyped remedies.

This point naturally does not require further explanation. But, with the exceptions already mentioned, I have had no such experience.

Especially enduring have been the recoveries from systemic depression, including dyspepsia, headache, spinal pain, constipation, dysmenorrhœa, amenorrhœa, palpitation of the heart, mental debility, localized rheumatism, etc. Not only have my patients remained in possession of newly acquired general strength, but, after completing the treatment, have progressed, apparently by the very inertia of this ascending vigor, and thus have gained in weight, in the color of the cheeks, in the ability to sleep soundly, in steadiness of appetite and, best of all, in mental clearness, balance and repose.

A patient whose ailment, for example, is constipation, or dysmenorrhœa, will, upon the first hint of recurrence, return for a single application of suggestion, and thus can be kept in normal condition.

It is surprising, however, to observe with what tenacious firmness those, who, at the outset were in the grasp of a mere prejudice against this treatment, medical men wholly ignorant of the action of this remedy upon their own patients, men technically unfamiliar with the subject, who do not draw from observation, but from preformed opinion, or the evidence of others who have only a tiny support for a large assertion, it is surprising, I say, to note with what tenacity these objectors cling to their belief, in the words of one of our otherwise intelligent colleagues, namely, that: "Hypnotism is distinctly harmful," and this is given as a would be professional opinion.

Conservatism is the backbone of our profession. But, conservatism does not necessarily mean knowledge. It is, or should be, caution in view of insufficient information. But an opinion like that I have quoted,

so clear, sharp and uncompromising (liberal too, in view of what hypnotism has accomplished), means, or should mean, that it rests upon a basis of solid, unshakable proof. I should like to hear that evidence and analyse the method of treatment thus condemned.

Apparent disturbance in a few cases is no argument against the value of hypnotic suggestion in the cases now numbering scores of thousands, in which there followed only beneficial results. And in the few instances which can be cited as unfavorable, let it be asked whether the gentle, inoffensive methods of the Nancy School were used, or, under the absence of proper suggestion, the harsher methods which exhaust and the frequent causation of hallucinations which might do harm, and, except for psychological study, are wholly useless?

Moreover, do the opponents of hypnotism forget that idiosyncracies are not confined to the effects of morphia, belladonna, antipyrin, *et cetera*, but may also extend to hypnotism? There are individuals who cannot smell a rose without distress. Why not banish rose-gardens and morphia? Why not dispense with ether? It certainly has been the cause of fatal arrest of the heart. What would be thought, especially by the men who pronounce hypnotism "distinctly harmful," of a proposition to abandon morphia and chloral because they were "distinctly harmful," this verdict having been derived from cases in which unusual idiosyncracies rendered these drugs unbearable?

There would be a better argument in favor of doing away with the drugs than there possibly can be for pronouncing against hypnotism, because, no matter how you administer your morphia, or chloral, you may destroy your patient, and their benefits are wholly derived from their poisonous effects. Whereas, in the use of hypnotism you avoid the creation of hallucinations several times daily, and of exciting hallucinations at all times. You hypnotize by quiet, gentle, *verbal* methods and follow by suggestions which inevitably leave the patient in a tranquil condition, and which also have controlled both hysteria and insanity.

The Berlin correspondent of *Le Semaine Médicale*, referring to cases of death following the injection of Koch's fluid, recently writes: "But I conceive that it is always necessary to keep in mind the individual disposition, and that it is not unreasonable to admit that there may exist in a person a sort of idiosyncrasy in regard to Koch's remedy, as is likely to be the case in the use of any other remedy."

It is useless to multiply argument upon this point. Idiosyncrasy is a possibility in any patient, but in spite of this, I contend that by wise suggestion hypnotism may always be safe, and I use idiosyncrasy merely as a supposition, for, I have never met it in any of the patients whom I have hypnotized, neither have any other hypnotizers, who confine themselves to the Nancy method, encountered it in their cases.

Krafft-Ebing's case has been used as a proof of the dangers of hypnotism. What are the features of that case?

In the preface to his monograph, Krafft-Ebing says: "Significant and practically important facts for experimental and psychical therapeutics will, I am convinced, come from this source"—namely, hypnotic suggestion.

Before the patient came into Krafft-Ebing's hands and during her stay at the clinic in Pesth, "she was very frequently hypnotized, not only by physicians

<sup>1</sup> Read before the Boston Society for Medical Improvement, January 26, 1891.

who had a right to do so, but also by unauthorized persons and even by laymen." At this clinic suggestions of an agitating and absurd nature were made to this patient, for example, of a snake, of an intensely cold bath, of intoxication, of nausea. Then she is a dog and can only bark, and she goes on all fours, etc., etc.

In October, 1887, Kraft-Ebing at his first interview finds the patient in a very cloudy, absent-minded condition, with a glazed stare. The next day her mind was clear and she said she had escaped from the clinic at Pesth, having found the constant hypnotizing unbearable.

Her father was intemperate and died by suicide, mother sickly, and died paralyzed as a result of apoplexy. Brother and one sister committed suicide. Another sister was subject to hysterical convulsions. Maternal grandfather shot himself while insane. Patient had suicidal tendencies. Her menses were very irregular. She was a kleptomaniac and knew nothing of the acquisition, nor of the possession of articles she had stolen. Her history contained auto-suggestive embellishments and delusions of memory. There had been periods of abnormal unconsciousness which the patient could not recall. Much if not all of this condition existed before she was hypnotized. She had hysterio-epileptic attacks during seven years previous to Kraft-Ebing's experiments. She had hemianesthesia and reversed sexual inclinations. Surely here was a case which should have been guarded from all suggestions of hallucinations.

At the outset Kraft-Ebing's opinion was that the patient should be sent to an asylum in her own country, because of her pitiable condition, but that it was possible that she might gain a better future by means of continued therapeutic suggestions.

He began by suggesting a great variety of hallucinations and by post-hypnotic in addition to regular therapeutic suggestions, but says: "*No detrimental effect upon her disease was ever observed as a result of hypnosis when proper precautionary suggestions were made.*"

Hallucinations, many of them of an exhausting nature, were steadily created. With reference to this point Moll asks: "Is it possible to expect a quiet nervous condition on wakening a patient after an hallucination of a conflagration," and adds: "I have frequently seen days of discomfort follow night-mare." During these experiments Kraft-Ebing's patient was made deaf by suggestion. The magnet, as Charcot claims it will, did not restore hearing, but the words: "You hear" written upon the arm, did so. The magnet excited muscular contractions of the arm. So also did a wooden magnet. These were curiously effective arguments in favor of suggestion and against Charcot's claim for the magnet.

After being in Kraft-Ebing's hands eight months, the patient, by order of the Hungarian Ministry, was sent to an asylum in Pesth, in a far better mental condition than when she entered Kraft-Ebing's hospital.

Five months later the report was that: "Her mental condition continues favorable, nothing psychically abnormal, when awake. She is obedient, industrious, free from hysterical convulsions, sleeps well, menstruates regularly, and, with the exception of a chronic headache, is mentally and physically well."

"Whether this favorable change of her condition," says Kraft-Ebing, "depends upon an intermission of the neurosis, or upon the cessation of the hypnotic experiments, or whether it be the result of the anti-suggestive obedience to the commands given during the hypnosis on June 7, 1888 (just before she set out for Pesth), must remain undetermined. It is, nevertheless, remarkable that, with one exception, which was overlooked in the suggestions, all should have happened as suggested.

"Were this the true significance, the therapeutic value of correct suggestion would receive further confirmation. Then, in case of renewed disturbance of her favorable condition, the repetition of suggestive commands given the patient on June 7th by her own desire, would offer hopes of possible recovery and seem to be the duty of the physician."

Later he says: "I regard hypnotic suggestion as a valuable addition to the therapeutics of functional nervous diseases."

This case, then, proves nothing against hypnotic therapeutic suggestion, but merely shows the bad effects of creating hallucinations and of the intemperate use of hypnotism.

In this place naturally comes mention of one of my own cases,—that of a young woman, who, after some years of increasingly intense hysteria, became so violent that she destroyed her clothing, books, and everything within reach, and was so unmanageable that I sent her to the McLean Asylum, where she remained twelve months. Thus far she had never been hypnotized. After her release she one day was seized with a convulsive attack because of fright caused by sudden palpitation of the heart. For the first time, I then hypnotized her, and the suggestions made created absolute calm and left the patient in possession of a well-balanced mind. Since that time, twelve months ago, occasional application of hypnotic suggestion has not only kept her free from mental disquiet, given her better appetite and serene sleep, but has called forth expressions of satisfaction for the comfort she has derived from this treatment. There could hardly be found a better refutation of the assertion that hysterical subjects are made worse by hypnotism.

In the *Revue de l'Hypnotisme* for December last, Bernheim gives utterance to his latest views after nine years of hypnotic practice, with reference to the dangers of hypnotism. In this extract from a lecture to his students, he says: "Does suggestion as we practice it, with a therapeutic object, present any danger whatever? . . . It is a singular thing that some years ago, I recall that when a practice more bloody than hypnotism—ovariotomy—made its entrance into modern surgery, eminent professors in the society of surgery, were found, who said: 'this operation belongs to the office of the public executioner.' Today, ovariectomy no longer has any enemies. One goes so far as to perform the operation upon the hysterical under pre-text of curing them. No voice is raised against this procedure, but anæsthetics are poured upon the inoffensive suggestion which does cure hysteria. I appeal to the numerous students and colleagues, who for several years, have followed my clinic: If you have seen a solitary fact which bears witness to a serious inconvenience in the suggestive method, when well applied, announce it.

"I have seen many neuroses cured; I have never

seen one caused by suggestion. I have seen the intelligence restored: I have never seen a mind enfeebled by suggestion. Without doubt it is not a protection against all eventual nervous affections. Among the numerous cases of neuropathy which apply for this treatment, there are, for example, subjects of a mental alienation which suggestion will neither prevent nor cure. Among these are those who are predestined, in whom subsequently the latent and native germ of cerebro-spinal maladies or of mental alienation may explode. To attribute to suggestion that which is due to innate conditions, is to commit a clinical error against which my long experience protests. Of the cases of neuropathy treated by the bromides or valerian, are those, and in equally large number, who one day or another will pay their tribute to the original vice of their organization. Does one, therefore, accuse bromides, valerian, or hydropathy of creating hysteria or insanity?

And he quotes well-known men in Paris, Toulon, Munich, Zurich, Geneva, Vienna, Breslau, Berlin, Amsterdam, London, Stockholm, and many others, who apply hypnotic suggestion according to the Nancy method, and who in thousands of cases have never seen the slightest serious result.

Moll,<sup>8</sup> referring to hypnotism by means of a prolonged use of bright objects, electric lights, etc., says: "Fixed attention too long continued may be followed by nervous debility or nervous excitement. But I have never seen any one become 'nervous' whom I hypnotized verbally and to whom I made no exciting suggestions."

This is an important point, for nothing has caused such misconception of hypnotic suggestion as have the production and the effects during hypnosis, of frequent hallucinations and post-hypnotic suggestions.

In a letter I have just received from Liébeault he says: "The accidents in hypnotism are due wholly to the ignorance or giddy tricks of the operator."

In a note from Van Renterghem and Van Eeden, they refer me to their "*Comptes Rendus*," in which they say: "The dangers of hypnotism are of two different orders. They are the consequence of unskilful and injudicious suggestions (that is of hallucinations), and especially of subsequent auto-suggestions" which are due to hallucinations aroused during the hypnosis. They further say: "As a general rule, one which we rarely overstep, we abstain from suggestions which do not accord with the normal functions of the organism."

It would be just as sensible, medicinally, to give a patient too much alcohol in order to enjoy his intoxication, or too cold a bath in order to see him shiver, as to create needless hallucinations during hypnosis, or make any but necessary therapeutic suggestions.

"It is insufficient technical knowledge that is dangerous," says Moll,<sup>8</sup> "not hypnotism. It is as necessary to know the right way as in using a catheter. Hypnotism properly used is as harmless as electricity properly used."

The many false passages made by unskilled hands have not banished catheters, that I have heard.

Physicians in this country, probably, and without a doubt the laity, have been influenced by newspaper reports of the discussion of hypnotism by the British Medical Association in August last. The daily papers have made it evident that the decision of the Asso-

ciation was that the effects of hypnotism were enfeebling to the mind and nervous system. In some journals these conclusions were published as the formal conclusions of the British Medical Association and have given the public, if not physicians, an entirely false idea of the actual sense of the Association. The facts are as follows: Dr. Norman Kerr read before the Section of Psychology a paper bristling with senseless and wild denunciations of hypnotism under any and every aspect, thereby making his ignorance perfectly apparent. He even went so far as to aver that rather than have a man cured of intemperance by means of hypnotism, he would have him remain a drunkard!

The reception given to this paper by the Association is shown in a letter which I have lately received from Dr. Lloyd Tuckey, one of the participants in the discussion in question. He says: "I am glad to be able to assure you that hypnotism, far from having received a check at the hands of the British Medical Association, scored a complete victory at Birmingham. The *British Medical Journal*, of August 23d, will confirm my assertion, and it puzzles me to understand how the members of the profession got hold of such an incorrect version of the story. You will see that Norman Kerr, a cantankerous, advertising sort of man, with no professional reputation, was sat upon and that he failed to receive any support in his shallow and unscientific attack upon what he evidently knew nothing about."

Editorially, the *British Medical Journal* says: "In the long discussion which followed, one speaker after another pointed out that Dr. Norman Kerr had not brought forward a single fact in support of his statements." What the Association did do was the result of practical demonstrations made by Drs. Tuckey and Kingsbury. "Many speakers," continues the editorial, "admitting the spirit of scepticism with which they had come to the meeting, stated that they would leave it impressed with the necessity of having the subject thoroughly investigated."

A committee for this purpose was therefore appointed, and among others included Professor Gairdner and Dr. Yellowlees of Glasgow, Dr. Broadbent, of London, Dr. Suckling of Birmingham, Dr. Clouston of Edinburgh, Dr. Hack Tuke of London. The latter is a strong advocate of hypnotism and Professor Gairdner is well-disposed toward it. Dr. Norman Kerr, it will be observed, was not included in this committee.

My correspondent informs me that one meeting of this committee has already been held, and that a favorable report in July next is a reasonable certainty. He adds: "I feel very strongly that the future of hypnotism depends largely upon the character of the medical men who practise it. If we can combine the single-mindedness of dear old Liébeault with the science of Bernheim and Forel, there is no fear that hypnotism will ever again be relegated to quacks and ignoramuses. . . . I feel that here, at least, the method has taken such root that in spite of opposition our position is unassailable."

This letter and the editorial from which I have quoted, will, I hope, dispose of all misunderstanding relative to the true character of the discussion of hypnotism by the British Medical Association.

Dr. Tuckey further says, in reply to my question with reference to this point: "I have lately asked by

<sup>8</sup> Loc. cit.

letter at least twelve of the leading hypnotizers of Europe whether they have ever seen the slightest harm arise as an effect of hypnotism (as practised by the Nancy School), and the one reply is "never."

This also is Dr. Tuckey's personal experience.

The one salient point in the application of hypnotic suggestion which is not generally understood, especially by the laity, is that it is *suggestion* and not *hypnotism* which is the actual power in the treatment. And, further, that hypnosis is only a subordinate means to a suggested therapeutic result; that, verbally suggested, hypnosis is calm and restful; that, protected by wise suggestion, only quietude and refreshment will follow the sleep and, therefore, that the treatment is harmless and beneficent.

It has been reported that a medical student in Italy, previously well, became hystero-epileptic as a result of too much hypnotism. In the first place I entertain the gravest doubt as to the perfect health of this student before he was hypnotized. If he were well, for what was he hypnotized? Secondly, the report that the condition was evoked by repeated hypnotism undoubtedly means that the student, being a good subject, underwent a careless and too frequent application of hypnotism by a variety of people, without protection from proper suggestions and was exposed to the ill effects of hallucinations suggested by those who cared only for the amusement or wonder created. Otherwise such a result could not have happened. One might as well overfeed a sick man with improperly prepared food and then condemn the food as unfit for use in any case.

No one, I suppose, would be so simple as to assert that no limits are to be set to the use of hypnotism. Such a claim would not be set up for the use of electricity, or of massage or dumb-bells, and yet would be just as reasonable. In the administration of drugs the physician does not prescribe by the pint nor the handful. He protects his patient by carefully regulated doses. So does the hypnotizer.

Let it be said here that Bérillon of Paris, makes a specialty of treating epilepsy by hypnotic suggestion and has met with success, thus showing that an expert in this form of treatment does not consider epilepsy a bar to the use of it.

There are so many cases of illness which resist other methods of relief and yield easily to suggestion, that it were simply a wrong to deprive such cases of it. Because in a few scattered instances hypnotism has been followed by the natural effects of ignorant or over-application of it, the treatment is to be abandoned, is merely to say that because electricity, morphia, ether, hot vaginal injections, carbolic acid, mercury and many other remedies in common use, have created disturbance, or have done harm, they also must be laid aside. This is illogical and lacking in common-sense.

(To be continued.)

INCREASED CONSUMPTION OF ALCOHOL.—The *British Medical Journal* records the fact that in 1890 there had been an increased alcoholic expenditure in the United Kingdom of about thirty-six million dollars over 1870. Nearly one-half of this increase was for beer, only one-third for spirits, and less than one-fourth for wine. The average amount spent in all intoxicants in the past year, been seventeen dollars per head of the population.

## THE TREATMENT OF FIBROID TUMORS OF THE UTERUS AFTER THE METHOD OF DR. APOSTOLI.<sup>1</sup>

BY JOHN HOMANS, M.D., BOSTON.

CASE XXV. Mrs. W., forty. An instrumental abortion sixteen years ago. Noticed abdominal enlargement six months ago. As a rule, hæmorrhage when unwell. Slight dyspnea for years. Bowels regular, appetite poor, sleeps well. Feels weak. Anæmic looking. Has lost flesh in past five weeks. Vaginal examination shows presence of fibroids of uterus of various shapes.

From July 14 to August 7, 1888, seven treatments; sound inserted five inches; positive pole, duration five minutes, dosage 50° to 125°. At this time feels first-rate. In September reported that she had "been pretty well." Two more treatments same as above, dosage 100°. Feels well. Flowing unchanged.

It will be seen, in the answer to the circular, that the tumor has increased in size during the last two years.

October, 1890. Health: I am feeling pretty well. Tumor got considerably larger on the left side. Menstruation irregular; two months not so profuse. I have a terrible lot of pain on left side. Am stronger. Fat over the stomach not increased. Am not much stouter. I can walk better; I don't think I can stoop as well. No children. Treatment: Not until this last two months; the same as you treated me.

CASE XXVI. Mrs. H., forty-two. Youngest child sixteen years old. Excessive flowing at catamenia, increasing since tumor first noticed about two years ago. Pain in back, bowels irregular, frequent micturition. Globular, movable tumor about six inches in diameter, extending to umbilicus, with one or two projections.

Two treatments in July, 1888; positive pole, five minutes' duration, dosage 95° to 100°. Each treatment caused considerable hæmorrhage.

It will be seen, by the answer to the circular, that this patient is much improved.

Health very good. A little decrease in size of tumor. Menstruation regular. Am very much stronger; do all my own work. Fat increased. Can walk better; more I walk, the better I feel; can stoop better. Pain: none only when I work hard. No children. No treatment.

CASE XXVII. Miss W., forty. Catamenia always painful. Flowing normal. Great pain in right iliac region and groin, followed by nausea and vomiting. There is a day or two of intense headache and backache, with general pelvic soreness. Is comfortable only about half the time. Fibroid, size of filbert, on anterior, and another (larger) on posterior junction of neck and body of uterus; third fibroid projects towards rectum.

In July, 1888, two treatments; sound inserted three inches; negative pole, duration five minutes, dosage 45° to 70°.

Died, December 5, 1888. Cause of death unknown.

CASE XXVIII. Miss C. Noticed tumor first about eighteen months ago. Has increased rapidly in size. Some pain. No excessive flowing. Stout, strong, well-nourished woman. Hard, roundish tumor, extending from pubes to an inch above umbilicus and within an inch of each anterior superior spine. Introduction of platinum electrode very difficult, as os was behind, and in right-hand upper corner of vagina.

From September 27 to October 16, 1888, three treatments; sound inserted four inches; negative pole,

<sup>1</sup> Read before the Boston Society for Medical Improvement, January 12, 1891. Concluded from page 256.

duration five minutes, dosage 80° to 95°. October 20th, reports that three hours after last treatment vomited; then had considerable pain for half an hour; flowed severely for three days. October 26th, fourth treatment, same as above, dosage 150°. Fifth treatment, sound inserted one and one-half inches; positive pole, five minutes, dosage 135°. October 27th, began to flow, with much pain in right side. Flowed till November 5th.

On November 6th, sixth treatment; gas-carbon sound inserted four and one-half inches; withdrawn twice; positive pole, duration in all nine minutes, dosage 115°, 120°, 130°. In the evening patient was seized with vomiting and great pain and tenderness over tumor, requiring morphine subcutaneously. November 7th, temperature 105°. November 8th, temperature 104.5°; pulse, 120; respiration, 40-50. Vomiting ceased. Pain persists, requiring morphine occasionally. November 9th, temperature 104°-105°; pulse and respiration rapid. Tongue dry and brown. Diarrhoea. November 13th, condition about the same. Brandy every two hours. Takes food well; no nausea. Most marked objective symptom is the rapid respiration.

This patient died on December 4, 1888. The temperature ranged between 100° and 105°, the symptoms being those of acute septicaemia, with pain in the side, in the shoulder, and in the arm, and, later on, diarrhoea and delirium. There was no autopsy. I consider that death was caused by septicaemia, and that the septicaemia was set up by the treatment. At the same time I regret that this matter could not have been settled by autopsy.

CASE XXIX. Miss C., forty-five. Catamenia always regular and normal till two months ago, when she flowed badly, with great pain, for a week, then had diarrhoea for two weeks, with severe pain in stomach and bowels. A rather pyramidal-shaped, many-lobed fibroid, with apex midway between left anterior spine and umbilicus.

On October 23 and 30, 1888, gas-carbon sound inserted five inches, changed three times, duration nine and twelve minutes, dosage 110° to 150°, positive pole.

After first treatment constant discharge, offensive at first, then colorless, which continued till November 13th, when platinum sound inserted five inches, positive pole, duration five minutes, dosage 125°. November 14th, discharge ceased.

December 10th, feels well, catamenia normal, no flowing. Fundus on a level with a line drawn from one anterior spine to the other. Tumor seems smaller. Abdominal parietes fatter.

In this case the treatment by curetting, and that only once, seems to have been of much more advantage than all the treatment by electrolysis.

Health good. Change in size of tumor not noticeable. Menstruation regular. Am stronger. Fat over the stomach increased. Have got stouter from 105 pounds to 122 pounds weight. Can walk; can generally stoop better; troubled at times. Occasional pain, due usually to over-exertion. Treatment: the year from October, 1888, to October, 1890, was one of great suffering. You will, perhaps, remember on the occasion of my last visit to you, in answer to my many complaints, you advised another course of electrolysis; but remembering how I run down, during previous treatments, and your own words when you advised me to stop them, I lacked confidence to begin again. However, I grew worse, and for something over two months was very sick, four weeks of which I spent (as I could not stand the expense of St. Margaret's in the New England Hospital, where I was most kindly cared for, and at the end of six weeks sufficiently patched up - though still very miserable - to enable me to take up my duties at the Crawford

House, White Mountains, for the summer. While there, the attention of Dr. Seth Gordon, of Portland, was called to my case, who assured me he could help me. Accordingly, October 5, 1889, I put myself under his treatment, and to his skill I owe the fact, that I am a comparatively well woman.

December 21, 1890.

MY DEAR DR. HOMANS: Your letter of November 25th finally reached me, having been forwarded to me here where I am spending the winter, as I did last year. Replying to your questions regarding Dr. Gordon's treatment, will say it was simply curetting, and that only once, and I did not take ergot, or in fact any medicine. I refer you to Dr. Gordon, who will, I know, give you gladly full particulars regarding my case. Please excuse my tardy answer. Yours, very truly, J. C.

CASE XXX. Mrs. C., forty-seven. One still-born child in 1872. Tumor noticed many years ago. Grows slowly, and causes bearing-down pains, weight and dragging sensation in ovarian region, pain in thighs. Excessive flowing, with catamenia. Uterus very movable; enlarged mostly on right side, where it extends to umbilicus; most prominent in pubic region.

In January, 1889, two treatments; sound inserted three and three-quarters inches; positive pole, duration five and one-half minutes, dosage, 15° to 55°.

October, 1890. Health not at all good. Increase of tumor; half as large again. Menstruation quite irregular, quite profuse; quite painful. No stronger; am weaker; much the same as during past year. Fat not increased. Cannot walk nor stoop better; no improvement in these respects. Some bloating and pain in abdomen of late. Pain in the legs. No children. Treatment: Very little; occasional electric treatment, but irregular.

CASE XXXI. Miss S., forty-two. Catamenia for past four years have been accompanied with excessive flowing, which has been constant for past month. Several small and movable fibroids.

From May 3 to June 5, 1889, five treatments; gas-carbon sound inserted four inches; changed twice; positive pole, average duration ten minutes, dosage, 40° to 120°.

Last period before treatment required twenty-seven napkins; first period after treatment only five napkins. Feels better in every way. Circular unanswered.

CASE XXXII. Mrs. W., fifty. Catamenia accompanied by excessive flowing and excruciating pain. Has lost flesh. Cannot walk without fatigue. Apt to have pain, like that of colic, at night. Many-lobed, somewhat movable and tender fibroid, fully as large as pregnant uterus of eight and one-half months.

From November 1, 1889, to February 21, 1890, ten treatments; positive pole; five with platinum sound inserted three inches, average duration seven minutes, dosage, 100° to 175°; five with gas-carbon sound, changed three times, average duration fourteen minutes, dosage, 70° to 150°. During the time flowed more profusely at catamenia than ever before. Pain much less. Looks and feels better at end of treatment.

October, 1890. Health about the same. Tumor not increased, about the same. Menstruation regular, profuse. Am not stronger. Fat not increased. Get tired soon. Cannot stoop better. No improvement in these respects. Have pain. No children. No treatment. I was taken sick in June at the time I was unwell, and since then my speech has been affected, so it is difficult for me to talk, and I have not felt as strong as I did before. I go out to walk every day, but tire quickly. I have been about the house since August.

CASE XXXIII. Miss C., forty-four. Fibroid detected three years ago. Since then excessive flowing, averaging three weeks out of four. Clots as large as small peas. Palpitations, weakness, etc. Anemic-looking. Good appetite. Sleeps well.

From this review it will be seen that we may expect, in the majority of cases, that the general health will be improved, that hemorrhage will be diminished, that locomotion will be made easier, and that pain will be lessened; but we must almost never expect diminution in the size of the tumor, and seldom its arrest in growth. Out of thirty cases, ten increased in size, and sixteen remained the same; but the sixteen that remained the same were growing very slowly, if at all. I have learnt enough about the treatment *à la Apostoli* to know that its results are not certain enough to induce me to pursue it as a routine treatment, and that it is occasionally fatal; through the fault of the surgeon, if you please, I am willing to admit, but still once in a while fatal. If the practice of a method to be efficient and harmless requires the presence of the inventor as well as his apparatus, then its beneficial effects can only be experienced in the presence of the inventor, and patients must go to him. Such a method can hardly be of general use. Dr. Bigelow's litholapaxy, for instance, can be practised by any intelligent and competent practical surgeon with almost as good results as if practised by Dr. Bigelow himself; but electrolysis for fibroids, *à la Apostoli*, has not been as encouraging and efficient and harmless in my hands as Dr. Apostoli's books would lead me to suppose it ought to be. I have hardly used my battery during the past year.

From December, 1887, when I began the practice of electrolysis, *à la Apostoli*, I have operated by abdominal section fifteen times for the removal of uterine fibroids, with fourteen recoveries. So that it may be inferred that I have found nothing sufficiently curative in electrolysis to make me lay down my knife, and never take it up.

In conclusion, I wish to thank Dr. Knapp, and my nephew, Dr. John Homans, 2nd, for their help in preparing for the treatment and in carrying it on. I had intended to have looked up all the cases that I have seen during the last three years, particularly those who have received no medical or surgical treatment; but the amount of labor and correspondence required has prevented my accomplishing this work, which I hope, however, is only postponed.

#### NOTES OF FIVE CASES FROM DR. APOSTOLI'S CLINIC IN PARIS.

BY GERTRUDE W. VAN FELT, M.D., BOSTON.

In spite of their incompleteness, I have thought it worth while to record the following cases from Dr. Apostoli's clinic, the histories of which were taken during the winter of 1889-90, partly from his notes, to which he courteously gave me free access, and partly from the patients themselves. They may be of use, I hope, in supporting other and more conclusive evidence as to what may often be accomplished in a short time, and also as indicating something of Dr. Apostoli's method of work. My object in mentioning many minor symptoms occurring after some of the treatments, is to give an idea of what Dr. Apostoli considers indications for repeating or deferring the treatment. I think, judging from what I saw during parts of three consecutive winters, when I was a regular attendant upon the clinic, that these results show the average success obtained. Sometimes they were

more brilliant, at others not so good, but at all times they seemed to me to be carefully studied and fairly judged.

**CASE I.** Mme. B., aged forty-six years, seamstress, presented herself at the clinic October 15, 1887, in a weakened anæmic condition, complaining of uterine hemorrhages.

**History.**—Parents healthy. Patient, herself, has never been robust. As a child was subject to nervous attacks of trembling and malaise, though never lost consciousness. Menstruation began at sixteen years; periods lasted three to four days, and were painful the first day. After fifteen years of age always had slight leucorrhœa. Married at twenty years. Fifteen days after had a severe pain over right ovarian region, lasting one day. First confinement at twenty-two years, since which time she has never been well. She had two subsequent confinements at term, one at twenty-six years of age, and one at thirty-five years. All were normal, but increasingly difficult and painful, and each one followed by an increased loss of blood. The menstrual periods after each confinement became more irregular and profuse, lasting ten days after the third, and in addition being very painful. At thirty years she was suffering from much pain in the small of back and abdomen, and consulted a physician who removed two fibrous polipi, which improved her condition for a time. At thirty-nine years she was extremely weak and flowed constantly for three months. At this time another polyp was removed, which temporarily reduced the menstrual periods to seven or eight days' length. Was treated from time to time with injections and local applications, but only grew gradually worse. In two or three years began to flow all of the month except eight or ten days, and even then lost a little.

**Present Condition.**—Has not grown thin, but is very weak. Sleep frequently troubled by pains in right leg, in abdomen and small of back. The abdomen has grown in size, without a great sensation of weight. Pains not increased by walking or sitting, on the contrary, are rather better when walking. Menstruates every three weeks in great abundance with clots. During periods pain is less, much leucorrhœa. Appetite good; digestion, slow and painful after the periods, pyrosis. Nervous, without attacks. Globus hystericus often at time of periods. Bowels, bladder, heart and lungs normal.

**Local Examination.**—Total fibroid of uterus. Left lateral displacement of body, which is mobile, without any trace of ancient perimetritis. The fibroid seems to be developed on all the walls, especially on the antero-lateral.

**Measurements.**—From pubis to umbilicus, 18 cm.; from pubis to top of tumor, 13 cm.; depth of uterus, 13 cm.

October 15th. First intra-uterine galvano-caustic positive treatment; 120 milliamperes for five minutes. Well borne. Was not flowing at the time, but after the treatment flowed one hour. Menstruation began the 17th, was abundant until the 24th, and was not painful.

During the next inter-menstrual period, she received four similar applications. This period was longer than it had been for years. Catamenia usual quantity without pain.

December 8th. Eighth intra-uterine positive application; 150 milliamperes, five minutes. Not well

borne. During the night of November 24th, had considerable fever. Next day lost much blood, and suffered greatly. She received an intra-uterine application of the perchloride of iron, which checked the flow for a time, but increased the pain. She remained three days in bed. Discharge of blood not yet arrested.

December 10th. No flow since last treatment. She had a disinfectant intra-uterine injection on the night of the eighth, which seems to have produced a more rapid result than the galvano-caustic alone.

January 1, 1888. Menstruation began December 29th and lasted only three days. Except for a short time on the 14th, she had no discharge of blood between December 8th and 29th, which is the longest interval she has had for several years. She has also a feeling of greater freedom of motion. Sleeplessness, however, persists. Twelfth intra-uterine positive application: 140 milliamperes, five minutes.

January 14th. First negative galvano-puncture; 60 milliamperes, seven minutes. Small trocart entered  $1\frac{1}{2}$  cm., under chloroform, followed by a bichloride douche and tampon of iodoform gauze. Walked home without much difficulty after lying down for three hours.

January 19th. No pain until yesterday. Sleeps better, and says she has had more relief as a result of last treatment than any preceding. Second negative galvano-puncture: 50 milliamperes, six minutes. Large trocart entered  $1\frac{1}{2}$  cm. in posterior cul-de-sac, without chloroform. Injection and tampon. Suffered considerable pain in legs and pelvis after second puncture.

She then had two more intra-uterine positive applications at intervals of about two weeks, and on February 14th, the first positive galvano-puncture; 44 milliamperes, five minutes. Trocart of gold point entered posteriorly  $1\frac{1}{2}$  cm., without chloroform. She walked home in three hours after treatment. Was more relieved by this last puncture than any of the preceding. Worked all the next day without trouble.

February 25th. Menstruated from 20th to 23d inclusive. Second positive galvano-puncture; 45 milliamperes, five minutes. Gold-pointed trocart entered posteriorly  $1\frac{1}{2}$  cm. This puncture more painful than the preceding. Passed blood in abundance for one hour on 27th. Suffers all over abdomen. Does not sleep nor eat well.

March 12th. After the third positive galvano-puncture and sixteenth positive intra uterine application, her progress may be described as follows: Menstruated three to four days in December, January and February last, with medium quantity. No menorrhagia since December. Lumbar pains, and those on right side, which prevented her turning in bed, have disappeared. Complaint only of light pains in abdomen. Sleeps better. Eats but little, and general nutrition scarcely improved, but her mood is better.

April 21st. Menstruated from 14th to 20th; profuse during two days. Feels very weak. Twenty-first positive intra-uterine application: 130 milliamperes, five minutes. On going home had considerable hemorrhage which lasted from 21st to 22d. Suffered much all the night at entrance to vagina. Measurements show that the top of the tumor has receded 3 cm., and the depth of the uterus 4 cm.

She had four more intra-uterine applications between the 4th and June 9th, and two intra-uterine faradizations when she reported that she felt weakened on account

of pain in right ovarian region. She affirms that the faradization with the coarse wire has soothed her the most, after which she felt a sensation of absolute well-being which lasted eight days.

June 16th. Ovarian pain has not reappeared since the faradization of June 9th. Fourth faradization with fine and coarse wire, medium intensity, which produced a relief which lasted until June 30th. Menstruation began the 18th, six days late, which has not happened for several years. From 18th to 21st, flow was very slight; from 21st to 24th, abundant and painless. Twenty-sixth positive intra-uterine application, 160 milliamperes, seven minutes, with carbon electrode, which was applied successively to whole endometrium. Cervix more sensitive than body. She suffered in right iliac region after treatment, for three days. Tampon slightly bloody. Appetite better, patient stronger. Ovarian pain persists.

October 23d. Has not returned since July 31st, because she has felt well. Has better appetite, no malaise in working. Has had no period since August 9th. Says she enjoys full health. There is increase of flesh in abdomen, but fibroid is a little smaller. Pubis to umbilicus,  $19\frac{1}{2}$  cm.; pubis to summit of tumor,  $10\frac{1}{2}$  cm.; hysterometrie,  $8\frac{1}{2}$  cm. Semi-atresia of canal. Patient did not appear again at clinic.

*Résumé.*—She received twenty-eight positive intra-uterine applications of medium strength, and four positive galvano-punctures extending over a period of nine months. This was a case of fibroid tumor having as the most troublesome symptom, excessive menstruation which was relieved in two months. In ten months she was symptomatically cured, though the tumor was but slightly decreased in size. This is the common result, which I have seen occur frequently; and though Dr. Apostoli has had some cases of undoubted absorption, which will probably be published, he does not claim it for his treatment, on account of its rarity.

CASE II. Mme. B., twenty-four years old, came to the clinic June 7, 1887, for severe attacks of pain in the abdomen.

*History.*—Father was nervous, mother healthy. She was never strong as a child. Menstruation began at seventeen years, was generally accompanied by migraine and pain the first day, otherwise normal. Was married six years ago. Two years later gave birth to a child. Confinement was normal. Two weeks after this had severe pains in abdomen which ended in a hysterical attack with loss of consciousness. From that time up to the present date, which is four years, she has had ten such attacks. Also, for the last four years she has had very frequent though not constant pain in both iliac regions and groins, sometimes extending over the whole abdomen, and sometimes sharp and shooting in character. When she has this pain she is unable to walk, and is often obliged to keep in bed.

*Present Condition.*—She is extremely sensitive to pressure in both ovarian, in pubian and in epigastric regions. Since March last she has had menorrhagia three times a month. Walks well when not suffering from pain. Appetite good. Bowels constipated.

*Diagnosis.*—Slight metritis. Double ovarian pain in hysterical subject. Neuralgia of anus and fourchette. Slight vaginismus.

June 9th. First intra-uterine faradization, using the fine wire coil (of Gaiffe's battery). It was well borne,

but produced no decrease of the pain after ten minutes' application. Immediately followed by faradization with the coarse wire coil, which was painful. In two minutes it was stopped to prevent a threatened hysterical attack. Only slight pain on pressure at the end of this treatment.

She had eleven faradizations with the fine wire from this time to October, all well borne. By July the pain in the groins had disappeared, and was chiefly confined to the sub-pubic and anal regions. In August she was comparatively free from pain, but in September she had a severe attack of hysteria, lasting two hours, and accompanied with labor-like pains. Since then she has had a renewal of suffering in the ovarian region, with much tenderness, which is increased by walking or fatigue.

October 8th. Faradization with the fine wire, which relieved the pain considerably. The coarse wire was then used a few moments to produce the menace of a hysterical attack, which was immediately calmed by a second faradization with the fine wire. After this treatment almost all tenderness had disappeared.

August 17, 1888. Has been free from pain, except during the first day of menstruation, until this month. Treated as on October 8, 1887.

October 4th. Treated as usual, as there is still some pain. She had no more trouble until May, 1889, when the pains returned slightly and increased until August, 1889. In that month she had two treatments like the previous ones.

March 1, 1890. Was well until January, since which time, without appreciable cause, she has had ovarian pain for an hour or so almost every day. Treatment repeated. The bipolar intra-uterine electrode was always used.

**Résumé.**—This patient had had severe pain and marked ovarian tenderness much of the time for four years, which had incapacitated her for walking and working. She was an hysterical subject. There was no anatomical lesion except a slight metritis. There was entire relief after thirteen intra-uterine faradizations, extending over a period of four months. This effect lasted ten months, when two more treatments brought about immunity from pain again for seven months. At the end of that period the pain began to return, and two treatments were given with a like result, of producing relief for seven months.

I have selected this case because it is one of so many similarly treated and benefited at Dr. Apostoli's clinic.

**CASE III.** Mme. W., aged thirty years, dress-maker; came to the clinic October 22, 1889, on account of having intermittent pains in the lower part of abdomen.

**History.**—Has had three children in three years, confinements normal. Miscarriage of one month in January last, since which time she has not been well. For three months she was in bed, had more or less fever, and lost much blood. Caught cold after being up a few weeks, and was obliged to go to bed again for two months. Her periods at this time lasted from twelve to fifteen days. She entered a hospital where she received local treatment, and later she was treated for two months with electricity. Her condition was improved.

**Present Condition.**—Well nourished. Periods last eleven days. No menorrhagia nor leucorrhœa. Complaints only of heavy pains in lower part of abdomen.

**Local Examination.**—Local hypertrophy of uterus,

fibroid in character. Uterus tender on examination, and fixed to sacrum with posterior cellulitis. Bilateral otero-salpingitis. Hysterometry  $7\frac{1}{2}$  cm.

October 29, 1889. First galvano-caustique, positive pole, 40 milliamperes, five minutes. Well borne.

November 7th. No reaction after last treatment. Second galvano-caustique, positive pole, 60 milliamperes, five minutes.

November 21st. Is feeling better and has less of the sensation of heaviness in abdomen. Has passed menstrual period, which lasted eight days. Third galvano-caustique, positive pole, 50 milliamperes, five minutes.

November 30th. Had bloody discharge during night after last treatment. Very tired the next day. Ever since has had leucorrhœa, lancinating pains on left side and rather more of a feeling of weight. Fourth galvano-caustique, positive pole, 80 milliamperes, five minutes.

December 7th. Slightly fatigued after last treatment, some slight shooting pains which increased on 3d and 4th of December, and which were augmented by walking. Slight leucorrhœa.

Present local condition compared with that before treatment: (1) There is less tenderness of uterus. (2) Uterus is more movable. (3) The exudate is less and the annexes are more clearly defined. Fifth galvano-caustique, positive pole, 70 milliamperes, five minutes.

December 19th. No pain nor reaction after last treatment. Menstruated from 10th to 15th, and lost less blood during that time than usual. Scarcely suffers any at present. Says she feels much better and can walk better. Sixth galvano-caustique, positive pole, 60 milliamperes, five minutes.

December 26th. Lost a little blood after last treatment. Seventh galvano-caustique, positive pole, 50 milliamperes, five minutes.

December 31st. The day after last treatment was taken with pains in lower abdomen which were quite severe, increasing in the night. At the same time epigastralgia. To-day is somewhat better.

January 4, 1890. Is better. Eighth galvano-caustique, positive pole, 65 milliamperes, five minutes.

January 18th. Menstruation began the 7th and lasted four days. Less flow than last time. Suffers still a little on right side. Ninth galvano-caustique, positive pole, 90 milliamperes, five minutes.

January 25th. Improves from day to day. Tenth galvano-caustique, positive pole, 50 milliamperes, five minutes.

**Résumé.**—She received during three months ten intra-uterine applications with the positive pole, none exceeding 90 milliamperes. The local condition was improved anatomically, and the menstrual periods were reduced in length from eleven to four or five days. She felt herself to be much better and stronger.

**CASE IV.** Mlle. A., forty-four years old, cook, came to clinic October 15, 1889, for abdominal tumor.

**History.**—Menstruated at seventeen years. Periods normal until twenty-four, when she began to suffer from dysmenorrhœa. Since thirty-six years of age has had more or less leucorrhœa, and since forty has had some pain in the abdomen. One year ago she began to notice that she was growing large in the abdomen, and when tired she had pain there. During the past year she has had sharp, shooting pains throughout the abdomen, and severe dysmenorrhœa.

*Present Condition.*—Slight leucorrhœa; no hæmorrhage; sleeps well, digests poorly. Finds it very painful and difficult to walk and work. Bowels obstinately constipated. Micturition frequent and difficult at or near the menstrual epoch. Feeling of great weight and heaviness in abdomen.

*Local Examination.*—Large interstitial and sub-peritoneal fibroid, having one lobe in recto-vaginal wall, extending above umbilicus, and mobile. It measured as follows:

Circumference at level of umbilicus . . . . .	100 cm.
" below umbilicus . . . . .	105 cm.
" above umbilicus . . . . .	85 cm.
From pubis to xiphoid . . . . .	43 cm.
" top of tumor . . . . .	29 cm.
" umbilicus . . . . .	23 cm.
Between anterior superior iliac spines . . . . .	33 cm.
Depth of uterus . . . . .	12 cm.
Medium thickness of skin below umbilicus . . . . .	20 mm.
" " above umbilicus . . . . .	20 mm.
" " to left of umbilicus . . . . .	14 mm.
" " to right of umbilicus . . . . .	15 mm.

October 19th. Since examination has had much abdominal pain and headache. First galvano-caustique, positive pole, 60 milliamperes, five minutes.

October 24th. Felt well the evening of treatment; no reaction. She can walk and work more easily. Second galvano-caustique, positive pole, 50 milliamperes, five minutes.

November 7th. Feels better. No reaction from last treatment, since which time she has menstruated with much less dysmenorrhœa than usual. Third galvano-caustique, negative pole, 250 milliamperes, five minutes.

November 12th. No appreciable reaction. Felt much abdominal weight for two days, which has now disappeared. Prepared dinner for her family the evening of November 7th. Fourth galvano-caustique, negative pole, 300 milliamperes, five minutes.

November 19th. Lost some blood soon after last treatment, and again on the 13th. On the 14th, had some pain in right side, but has been able to work hard. Fifth galvano-caustique, negative pole, 300 milliamperes, five minutes.

November 23d. Has been very well since last treatment; no pain nor fever. Abdomen feels much lighter. Walks better. Sixth galvano-caustique, negative pole, 300 milliamperes, five minutes.

December 3d. Menstruated from 27th to 1st, notwithstanding which, has had no pain since last treatment. Feels much better and walks easily. Seventh galvano-caustique, negative pole, 300 milliamperes, five minutes.

December 17th. During the night following last treatment had a slight bloody discharge which increased the two following days. This was followed by pains in lower abdomen, especially on left side, which lasted twelve days, and which, though severe, did not prevent her from working. Eighth galvano-caustique, positive pole, 170 milliamperes, five minutes.

December 24th. No reaction after last treatment. Was well for four days, but on the fifth had pains in lower part of back, while the abdomen became very tender, with feeling of heaviness. To-day better.

January 1, 1891. Menstruated from 27th to 31st. Feels at ease, and though painful it was less so than usual. He worked notwithstanding. Ninth galvano-caustique, positive pole, 200 milliamperes, five minutes.

January 14th. Felt well after last treatment for four

hours, since then has been well and without pain. Tenth galvano-caustique, positive pole, 100 milliamperes, five minutes.

January 30th. Has been well since last treatment, with exception of slight flow for a quarter of an hour immediately following it. Feels very much stronger than three months ago, and walks easily. Menstruated from 24th to 27th. Very slight dysmenorrhœa; worked hard throughout period. Eleventh galvano-caustique, positive pole, 250 milliamperes, five minutes. Hæmorrhage after treatment, provoked probably by passing of the sound. Second application made immediately with carbon electrode in cervical canal for two minutes, which arrested hæmorrhage.

*Résumé.*—She received during three months eleven intra-uterine applications, six of them being of from 250 to 300 milliamperes current strength. Her chief symptoms were severe dysmenorrhœa and a feeling of weight and heaviness, making it difficult to walk and work. These were relieved after two treatments to some extent, and very markedly so after eleven, especially the feeling of weight.

CASE V. Mme. B., forty-four years of age, came to clinic August 8, 1889, on account of uterine hæmorrhages and pain.

*History.*—Married at twenty-six years. Health good up to this time. Became pregnant three times in three years, the third time with twins, and was confined each time in six and a half to seven months, giving birth to dead children. After the last confinement at thirty years, she had abundant leucorrhœa, and pain during sexual intercourse. Five years ago, consequent upon a fall, her menstrual periods became much more abundant, and lasted eight days. Since this time her health has been noticeably affected. Six months later, after another fall, the menstrual flow increased still more and has ever since been very profuse; gradually increasing to fifteen days, and lately often has not even ceased during the entire month. She was treated by ergotine and injections four years ago, but the only visible result of this treatment was abdominal pain.

*Present Condition.*—Appetite and digestion good. Slight constipation. Walks and works with difficulty. Much general weakness.

*Local Examination* reveals retroversion; endometritis; ancient exudate posteriorly; ovarian pain on right side.

August 27th. First galvano-caustique, positive pole, 50 milliamperes, five minutes.

October 1st. No reaction nor pain after treatment. Menstruation began September 10th; was preceded by considerable pain but lasted only five days. Second galvano-caustique, positive pole, 50 milliamperes, five minutes.

October 22d. Has been better. The hæmorrhages have been arrested. The menses appeared normally and lasted from October 14th to 14th. Dysmenorrhœa for two days.

November 7th. Menstruated from 29th to November 4th. Flow though much diminished is still abundant. For the first time since her illness she was not obliged to go to bed during her period. Third galvano-caustique, positive pole, 80 milliamperes, five minutes.

December 28th. Since November 7th she has had two menstrual periods; the first, severe, lasting six days, the second, almost normal, lasting five days. She

feels much better, and has been able to work most of the month. Fourth galvanocautique, positive pole, 70 milliamperes, five minutes.

January 18, 1890. Menstrual period from January 9th to 15th, only twelve days after cessation of last. Since then has felt quite well and been able to work. Fifth galvanocautique, positive pole, 100 milliamperes, five minutes.

February 20th. General condition since January 18th, good. Menstruated from February 1st to 4th. Is able to work easily. Sixth galvanocautique, positive pole, 120 milliamperes, five minutes.

*Résumé.*—She received six intra-uterine applications with the positive pole during six months, their strength gradually increasing from 50 to 120 milliamperes. The chief symptoms, hæmorrhage and pain, were both greatly relieved.

## RECENT PROGRESS IN PUBLIC HYGIENE.

BY SAMUEL W. ABBOTT, M.D.

### VENTILATION.

*The Use of Compressed Air for Sanitary Purposes.*<sup>1</sup>—Companies have recently been organized at Berlin and at Augsburg, to provide compressed air in cities and towns. Works of this sort are in process of construction at Fürth and Offenburg, and are contemplated at Würzburg and Bamberg.

The maximum price charged for air per cubic metre reckoned by the unit of atmospheric pressure is 1.2 pfennige (less than one-third of a cent). The cost of 420 cubic feet at a pressure of six atmospheres would be about twenty-five cents.

The *Gesundheits Ingenieur*, 1890, 457, in commenting upon this new enterprise says: "Since it is certain that in the course of a few years several towns will be furnished with air under pressure, the sanitarian should consider how he can avail himself of this new agent." A diagram is presented showing how water can thus be raised and be made available for domestic purposes, and among its uses are mentioned the ventilation of buildings and also the emptying of cesspools.

*The Removal of Foul Air from Apartments.*<sup>1</sup>—The old question is revived by the author, Dr. V. Budde, of Copenhagen, whether the air is most foul at the top, or the bottom of an occupied apartment. He comments upon Deny's plan for the removal of the foul air at the bottom of the room, by openings along the mop-board, and as Deny does not appear to have made experiments to settle the accuracy of his theories, Dr. Budde undertook a series of experiments for this purpose under varying conditions, in which he had the assistance of Messrs. Jensen and Struer. The experimental room was 4.68 by 2.59, by 3.11 metres, the floor area being 12.1 metres = 130.2 square feet, and the contents 37.7 metres = 1321.3 cubic feet. It was heated by a stove in one corner, and means were provided for measuring the air admitted and extracted. Tests were conducted with twelve stearine candles and a lamp. Temperature observations were made at five different levels. The measure of air-pollution was based upon the carbonic acid determinations which were made by Petterkofer's mode.

One important point which was noticed was the difference in volume between the fresh air admitted, and the foul air withdrawn for each of the experiments, the latter being in all cases nearly three times as great as the former. The balance must necessarily be due to natural ventilation by cracks, crevices and direct passage through the walls of the room.<sup>2</sup> The evidence in these experiments appears to have been in favor of a longitudinal exhaust-flue at the bottom of the room, which extracts the largest volume of polluted air in the most economical mode, that is, by ensuring the fullest possible utilization of the artificial heat produced within the chamber.

### AIR-FILTRATION.

With reference to the question of furnishing a supply of fresh air to hospitals and other buildings, which should be germ-free, Dr. Karl Möller<sup>3</sup> combats the conclusions of Dr. Petri, and as the first who undertook to filter air upon a large scale for industrial purposes, points out certain erroneous deductions.

He says air-filters are of two kinds; and for "germ-proof" filters he employs an ante-filter and ten layers of a specially thick, closely-woven, much roughened material; for dust-proof filters, only one thickness of a much less closely woven fabric. The latter are not entirely germ-proof. By this arrangement of the filter in a series of pockets, the cloth is used in a direction oblique to the air current, making an angle of 3° to 5° to it, while Dr. Petri arranged his cloth at right angles to the current. Dr. Petri also strained the capacity of the cloth, by forcing abnormal quantities of air through it. The author also adds that a woolly surface is one capable of entangling large numbers of germs, and that Dr. Petri neglected the precautions of sterilizing his cloth before beginning the experiments. He infers that Dr. Petri was thus led to believe that a large number of germs had passed through the cloth, which as a matter of fact, had been merely blown from its surface by the air-current.

### DISINFECTION.<sup>4</sup>

*On the Disinfection of Vaults with Lime.*—Dr. E. Pfuhl, of Berlin, after experimenting upon small quantities of typhoid and cholera excreta with milk of lime, applied the same to larger quantities in vaults and in tubs in actual use. He advises double the quantity of water that is theoretically required, that is, sixty parts of water to one hundred parts of quicklime. Assuming that one litre of slaked lime weighs half a kilogram (one and one-tenth pounds) in preparing a mixture for use one litre of slaked lime should be mixed with four litres of water. To test the action of the lime on faecal matter, red litmus paper colored blue in various shades by solutions of lime of various strengths, may be used. For cesspool matters, he recommends from one to one and a half litres of slaked lime to each one hundred litres of excreta contributed daily, the larger quantity being used for tubs and pails. The disinfection is best effected by daily use. No reliance should be placed on any mode of mixing, except a thorough mechanical stirring, and not upon a mere hand mode of mixture.

<sup>1</sup> Similar observations as to the passage of considerable quantities of air through the walls of apartments, were made by the State Board of Health of Massachusetts, in the course of a series of experiments at Athol and at Norton in 1884. Supplement to Sixth Annual Report, 1884, page 180.

<sup>2</sup> *Zeitschrift für Hygiene*, vol. vii, p. 379.

<sup>3</sup> *Zeitschrift für Hygiene*, vol. vii, p. 363.

<sup>1</sup> *Zeitschrift für Hygiene*, 1890, p. 507.

DISPOSAL OF THE DEAD BY CREMATION.<sup>5</sup>

The subject is now treated in a more scientific manner than formerly, and modern modes show a great advance over the old method of open-air burning on a funeral pile.

Venini, of Milan, employs a mode which involves the use of wood-gas and air impinging directly upon the body. Siemens puts the body in a crematory, previously heated with gas, and admits fresh air, which ignites the body. Emile Bourry, of Zurich, heats the furnace first with a coke-stove, using the heat developed in the combustion of the body to heat a cellular system, through which the air is passed, thus gaining economy of fuel, and saving of time between two cremations, so that it is not necessary to reheat the oven, as in the Siemens plan.

The preparatory heating occupies from eight to ten hours, the weight of coke being one and nine-tenths tons, costing forty to fifty francs, but for a second or third use, but a small fraction of this amount is necessary. The temperature in the furnace is about 700° to 800° (Centigrade).

Other advantages claimed for the Bourry system are:

(1) The chimney need not be more than ten metres (32½ feet) in height, and may be concealed in the building.

(2) The whole operation can be carried out in view of the relatives. Bourry lays stress on the visibility of the operation. The Siemens process, on the contrary, conceals it. The actual time of burning in the Bourry system is two hours without, and two and one-half hours with coffin. The cost of his crematory, exclusive of land, was about \$10,000.

## ADULTERATION OF FOOD.

*The Greening of French Vegetables by Copper.*<sup>6</sup>—This practice was introduced in France near the close of the last century, and is also mentioned by Accum in his work on "Adulteration" (1820), in which he cites the death of a young lady from eating "pickles impregnated with copper." This practise of "Reverdissage" has become in France a national industry, giving employment to 20,000 people and employing a capital of forty million francs.

The local sanitary authorities of Glasgow, Scotland, have taken summary action against this objectionable form of adulteration, in view of the fact that the French authorities had for many years forbidden their sale in France, while tolerating their export, but had finally withdrawn their prohibition at the persistent demand of the manufacturers.

The Scottish report sums up the matter as follows: "We can see nothing (in the French Report) but a feeble apology for yielding at last to a clamorous and persistent national interest. As representing the consumer, we may ask, why all these commissions, reports and experiment, to induce us to eat vegetables stained with sulphate of copper? The process is not necessary to preserve them, and thus enable us to have the advantage of a cheap vegetable diet at periods of the year when fresh vegetables are not to be had. It is not a case of submitting to a little risk, in order that another less marvellous source of food supply may be thrown open to the people. A French Minister of

Agriculture and Commerce tells us that the question involved is one of 'simply coloring with no other object but to please the eye.' The foolish public expects to get green peas at Christmas such as it gets from the market gardens in summer. The French manufacturer makes them to suit the whim. The consequence is that it eats stale peas greened with sulphate of copper *all the year round.*

"Internal, economic and political considerations form so large an element in this question, from a French point of view, that a single remark may be permitted on their British aspect and it is this: The cultivator of the genuine fresh green vegetable is grossly prejudiced by the substitution for the produce of our market gardens of last season's growth of foreign market-gardens 'colored so as to mislead the eye.'"

## DEATH FROM WATER CONTAINING LEAD.

It is rare that death is attributable to a water-supply containing lead. But there appears to have been such a case in Sheffield. In the Annual Report of the Health Officer for 1889, it is stated that a servant-girl, aged 21, died October 29, 1889, from paralysis of the respiratory muscles following well-marked symptoms of plumbism; the physicians at the hospital carefully investigated the case and excluded all other sources of lead save the water-supply. Analysis of the water in February and in November, 1889, revealed the presence of lead amounting to 0.4 to 0.5 grains per gallon.

PREVENTION OF SMOKE NUISANCES.<sup>7</sup>

It appears that much has been accomplished recently in England (where the burning of soft coal produces the same nuisance as in our Western cities), in the way of remedying the smoke nuisance. In Bolton several large manufactories have so far succeeded in controlling the difficulty, that scarcely any smoke now issues from their chimneys. The principle upon which the difficulty is remedied appears to consist in a peculiar arrangement of furnace and grate-bars, which causes the coal to be converted into coke in the fore part of the furnace, the gases disengaged being consumed as they pass over the incandescent mass further on. The coked coal subsequently burns without disengaging the carbon.

A similar result appears to have been attained in London, by means of Elliott's Smoke Annihilator; an apparatus in which the smoke is washed by spray, the carbon, tarry matter, sulphur compounds, and ammonia, being arrested in the wash-water, so that steam, carbonic acid, and colorless gases only escape from the chimney. This is accomplished by driving the smoke into a covered separating chamber, through the perforations of a central iron pipe, which is fitted with six rectangular iron paddles, perforated with holes. The chamber contains water up to the lower level of the pipe. As the smoke streams into the chamber the fan is rotated at a speed of 150 revolutions per minute, and churns the water and mixes it with the smoke. The smoke being at a high temperature, converts some of the water into steam, so that there are present in the chamber, water, smoke, spray and steam. The washed vapors are then passed into the shaft, and contain no solid particles. The apparatus is in operation in London, being applied to a tug, a saw-mill, and the smoke-flues of other works.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

G. G. SEARS, M.D., SECRETARY.

REGULAR Meeting, Monday, January 26, 1891, the President Dr. FREDERICK I. KNIGHT in the chair.

#### CHONDROMA OF THE EAR.

DR. J. ORNE GREEN: I have to show a specimen of either chondroma or osteoma of the ear. It occurred in a boy about seventeen years of age, who gives an early history of earaches and occasional discharge, none, however, for several years. He had been totally deaf in the right ear for two or three years, from the closure of the meatus by something that he felt with the finger. I saw him last October, and found the meatus completely closed by a large, firm, smooth growth, wholly free from inflammation, which I diagnosed as an exostosis, proving it by passing a needle through the tissue and coming directly down on to hard bone. I saw him first on account of inflammation below the auricle, which turned out to be an abscess directly below the auricle, which was opened, and the probe passed in about an inch along the line of the meatus, but did not strike any bone. A few days after that he began to have a little discharge from the meatus, evidently forcing its way by the obstruction. This was followed in a short time by pain more and more intense, and it was evident that something had got to be done. I suspected suppuration behind the exostosis, and advised operation, which was done under ether. The auricle was turned forward, and immediately I came down on the growth, which I found was loose, and with the director it was readily enucleated out of a carious cavity in the anterior wall of the mastoid. It came out perfectly clean, and there was some desquamative material and detritus in the carious cavity, which was removed. The cavity was thoroughly cleaned out; all the softened bone removed, and a drainage-tube put in and antiseptic irrigation thoroughly used. In two or three days the auricle was stitched into place, healed by first intention, and he made a good recovery. The hearing, which was almost wholly lost, was completely restored when the swelling of the drum membrane and of the tympanum had passed away, and when I last saw him the hearing was perfect.

The specimen is very unusual. I looked in vain to find any references of anything of the kind until I came to Grueber's last edition, and there I find that he describes three osteomas that he has in his collection, none of them operated on, and none of them loose as this one was. I say chondroma or osteoma. The tumor will be seen to be entirely covered with cartilage; and that led me to think it was a chondroma. Dr. Whitney made one or two sections of the bone, and says he found true bony structure, and is inclined to think it is an osteoma. Why it should be so completely covered with cartilage I should be glad to have some of the pathologists give an explanation.

The little discharge from the meatus proved to come from two bare spots of bone on this growth itself, and these two bare spots will be seen here. The growth evidently had begun to ulcerate at these spots on its surface.

DR. HAMILTON OSGOOD read a paper on

### THE OUTCOME OF PERSONAL EXPERIENCE IN THE APPLICATION OF HYPNOTISM AND HYPNOTIC SUGGESTION.<sup>1</sup>

DR. FOLSON: The subject is an exceedingly interesting one, and I have no doubt it has possibilities. As to the fact of hypnotism and hypnotic suggestion nobody has any doubt. So far as my own personal experience is concerned I have had no case that could not be better treated in other ways, and I am still studying it. I have not used hypnotic suggestion to any very great extent, but of course I should not hesitate to use it if I become convinced of its value. No doubt there are other gentlemen who know more about it than I do, and therefore I will not take the time of the Society.

DR. J. J. PUTNAM: My own knowledge of this subject is too slight to form an opinion. I believe Dr. Osgood is right when he says properly selected and properly treated cases can be benefited in this way. I think at the same time it is not remarkable that physicians have been conservative in the matter, and have shrunk from using it, and on the whole it is not altogether to be deplored. There are, it seems to me, certain physicians who practise this method well instinctively, just as certain ones practise one branch of medicine well, and another not. I think the prejudice against hypnotism has been a very natural one, and very few of us have had the opportunity to ascertain that we were mistaken, and to see just how it was used, and just what the character of the suggestions were, and the bad results which are to be avoided.

My own experience is confined to a few patients. I was successful in only one case, and that patient was benefited. I hypnotized her a number of times, and without my having suggested it she fell asleep at the same hour on successive days, although it was unusual to go to sleep at that time. It has seemed to me that the very fact of a new and unfamiliar treatment being tried might create in the mind of the patient prejudices and new apprehensions, and if not in the mind of the patient, in the minds of the friends of the patients. That is one reason why I have avoided this treatment.

PROF. WM. JAMES: My experience has been small. I should like to ask Dr. Osgood if he has never known any flushing of the face or any abnormal symptoms whatever to follow.

DR. OSGOOD: That occurs very rarely. In the early days of my experience I can recall, perhaps, two or three cases in which the patients have been sleepy afterward, and since this first occurred I have protected the patient by saying to him: "Until you see me again, you will be perfectly wide awake all day. You won't be sleepy in the least until 10 o'clock at night." And in the case of a patient who has sleepless nights I say: "You will sleep all night." I never have had a case of headache follow the treatment in all my experience. I protect my patients very carefully. In every case I repeat a formula to the effect that nothing but beneficial results will follow. Whatever the affection may be I say: "When you wake you will feel perfectly comfortable." And consequently I have no trouble. In short, I have had no experience of disturbance in any of my pa-

<sup>1</sup> See page 277 of Journal.

tients. During hypnosis I have so frequently watched for an increase in the pulsations of the heart, without finding it, that I no longer do so.

In reply to Dr. Putnam's allusion to the prejudices of the patient or of the friends, I can say that I never have any annoyance of that sort because I never urge people to be hypnotized.

PROFESSOR JAMES: I have found a tendency to headache after the first or second hypnotization, although contrary suggestions have been made. I think what Dr. Osgood said about idiosyncrasy is important. I do not know why there might not be latent neurotic tendencies in a person which that might set free. I had an experience this winter, in which, after the first hypnotization of the patient, he said he had a spontaneous trance in which he did something which was rather unfortunate, and that he had no memory of it afterwards. I do not know whether his story was genuine. Supposing it to be true that he had afterwards fallen into a spontaneous trance in which he did something very unfortunate to himself, should we for that reason say that hypnotism was a dangerous thing? I think by no means. It is an unexampled experience and a pure case of idiosyncrasy in that individual in whom evidently this strange, possibly epileptiform, unconsciousness was latent and ready to burst forth. This occurs in every branch of medicine.

I have been impressed with the fact that almost all the accusations against hypnotism have been vague. The only cases that are squarely reported are those of people who have been maltreated in public exhibitions. The other accusations are always vague, not backed up by definite cases, though in theory I am sure we must admit the possibility of idiosyncrasies, which this particular stimulus may, in certain cases, cause to explode. I confess that from my own observation of the preliminary stages in first sittings I am not disposed to agree with what Bernheim says, that there is no hypnotic state, that it is nothing but induced sleep—that which represents normal sleep. In my experience that tendency, in spite of suggestions, to have slight headache, a flushed face and the like, points to a process going on that is not precisely identical with normal sleep.

MR. HOVEY: I feel some hesitation in saying anything on this subject in the presence of gentlemen who have given it scientific study. This I do not pretend to have done. Something over twenty years ago certain alleged hypnotic phenomena came to my attention, and for my own information I determined to investigate them. Without very much searching I found a subject who was more than usually sensitive. (Here Mr. Hovey described several experiments, and continued): I satisfied myself that the hypnotic trance, whose existence was at that time very generally denied, was a reality, and I also became convinced that hypnotic suggestion, as it is now called, was of value as a remedial agent. I knew these things a year then, as I know them now. I confess to certain impatience at the unwillingness of people, and the poverty of physicians, to investigate hypnotism for themselves, or, failing that, to take the word of a few people who have investigated it. Is the tendency to be more open, so slow to admit what so many of us already know to be true calculated to retard the progress of the science and confidence in the procedure? Is the probability the use of hypnotism as a remedial agent, and moreover, Doubtless, in the

future as in the past, it will be practised by incompetent persons. If this has been largely the case in the past, perhaps the fault lies, in a measure, at the door of the medical profession, whose unwillingness to inquire into it seriously has had much to do with relegating it to hands of charlatans. I have no doubt that legislation on this subject will be asked. Perhaps that would be the most dangerous thing of all, for legislation seldom accomplishes the object sought. But if the practice of hypnotism is to be restricted by law, is it not fair to ask that it be restricted to those who are competent? The fact that a man is a physician is no proof that he is competent to practise hypnotism. For nearly a century the profession denied its existence. Is it becoming in physicians, now that at last they have discovered their error, to face about and ask for laws restricting the practice of hypnotism to themselves, and forbidding it to all others?

DR. F. C. SHATTUCK: I have used the method a little, and in one or two cases I think with benefit; in one case I think with distinct harm to the patient, and I stopped it. I thought the patient was getting dependent upon it. The patients on whom I have practised hypnotism have been almost entirely hospital patients. I think they are safer people on whom to practise it, because they come into one's orbit a short time and then disappear. I have a feeling, perhaps founded on ignorance, that it is possible for a man to acquire more influence over a private patient than it is desirable to have by this means, and if I can attain my end, I should prefer to do it by slower means, which certainly have not this disadvantage. I have recently seen in consultation the case of a gentleman who, I think, was seriously harmed by being hypnotized several times. I have but little question that the method has an application, that it is likely to be perhaps of distinct use, but I think that it is to be carefully used.

DR. OSGOOD: The actual remedy in hypnotism is suggestion. It is necessary to get at the patient's mind, in order through his mind to reach his body, and therefore we put him into a sleeping condition, which renders his mind susceptible to suggestion.

My patients have no headaches after having been hypnotized. The proper suggestions prevent anything of that kind. In any case it is a very rare occurrence. It happens only after the first sitting, and is probably due to the novelty of the treatment. With reference to Dr. Shattuck's fear that a patient may become dependent upon this treatment, I can say that I have seen nothing of that nature. If I did, I should simply suggest to the patient: "You will never desire this treatment again"; or: "I never can hypnotize you again, neither can any other person"; and thus the matter would be ended. So soon as my patients are relieved they discontinue the treatment as practically as if it were a drug. If a patient were very susceptible to hypnotism I should protect him, and especially her, by suggesting: "Nobody but myself can hypnotize you until I give permission." Suggestion covers every point that can be raised with reference to this treatment. Care must be taken at all times, and in suggestion this care may always be found. Under its influence no unpleasant sequelæ can follow.

Dr. Shattuck thinks it might happen that more influence could be acquired over a patient than would be desirable. Practically this will not occur to the mind

of the hypnotizer who is worthy of trust. The patient never would exhibit the effect of undue influence unless it were suggested by the physician. Bearing in mind that suggestion is the root, trunk and branches of the treatment, every such liability disappears, that is, if the physician be honorable. My chief desire is that my patients recover. That is the only ambition I have. Any personal element in the use of hypnotism never would occur to me. I have several patients who would obey any suggestion, but I confine my suggestions strictly to the normal functions of the mind and organism of the patient, that is, I never suggest hallucinations.

In relation to the hypnotic sleep: The great majority of the Naucy School say it is a normal sleep. Others say it is not. My experience leads me to agree with the former. Professor James will recall a good illustration of a somnolent yet sub-conscious condition given in one of his papers, on "Will" I think,—that of a man lying half-awake in the morning, who says to himself: "I must get up," and yet lacks power to do so. No one will say he is not in a normally sleepy condition. His consciousness is awake, but nervous force is concentrated upon the thought: "I must get up." Suddenly this force explodes upon the body. Motor obedience follows, and before he knows it the man is out of bed. If one will test himself at early morning, I think, with few exceptions, it will be found that there exists this same difficulty of moving arm or leg, even after the mind decides that it is time to rise. It is so in my own case. Motor obedience always comes in form of a sudden eruption of nerve force upon the body.

Does sleep mean absolute unconsciousness? If so, why does an individual awake from sleep at an hour which he has fixed in advance? I am a light sleeper. Following the nights during which I hear the clock strike two, three, four, five, I awake in the morning perfectly rested. The moment the clock has struck I sleep, and it seems but a few moments before the hour strikes again. Does it therefore follow that I do not sleep?

In this way I account for much of the asserted nights "without a wink of sleep" in invalids. Their very look proves that they have slept. In fact, failing that, their other symptoms would intensify.

The stages of hypnotic sleep seem to me natural somnolence of varying degrees of intensity. After hypnosis I frequently ask very intelligent patients whether they feel as if they had been asleep. The reply, given between stretching and yawning, is, first a look of surprise, and then: "Asleep! Why of course. What else?" And when I remark that some people think the repose is not a normal sleep, the response usually is: "That is nonsense. They probably never tried it."

In reply to the question by the Chairman, touching a person's responsibility under hypnotic suggestion, I will say that in my reading I have never been able to find a well-authenticated case of crime committed under suggestion. The so-called "laboratory crimes" are common enough, but, once released from the operator, habit reasserts itself in the subject. Even during hypnosis many persons resist the suggestion of a criminal act. Habit in a man's life is everything. If the patient be a person of moral strength, and he is told, under hypnosis, to steal a watch on the following day, I think, in nine hundred and ninety-nine out

of one thousand cases, habit—the moral instinct—would prove stronger than the suggested impulse or the post-hypnotic influence, and the theft would not occur. Especially would this be true if the suggestion included a deeper crime, as murder.

Admitting, however, that there are people so susceptible and morally so weak that they could be used as instruments of crime, the responsibility would rest with the operator. In that case the procedure will take care of itself, because the law will deal with such forms of crime and be on the watch for them, so soon as it becomes familiar with the possibility of such misuse of hypnotism. A hypnotizer would not dare suggest a crime, because, under a new hypnosis, the instrument might freely expose the source of the criminal impulse.

DR. FITZ: I would ask of Dr. Osgood his opinion with reference to hypnotizing against the will of the patient.

DR. OSGOOD: It would be impossible unless the will were weakened by fear or by superstition. As Bernheim says: "*No one can be hypnotized unless he have the idea that he is going to be hypnotized.*"

DR. C. F. FOLSON reported a case of

#### GENERAL PERIPHERAL NEURITIS,

in which arsenic was found in the urine and in the wall paper of the patient's sleeping-room. There was also the mental condition which is found in the early stage of general paralysis and in the so-called lead encephalopathy. There was no lead found in the urine. If the mental failure were due to the arsenic, as seemed in part at least probable, since the symptoms all improved together under treatment, that indication, so far as he knew, had not yet been reported. It is not safe, however, to infer that all the symptoms found in a patient suffering from some toxic agent are due to the poison, a mistake which, in his opinion, was easily made in a community like any where arsenic and lead are so often found in the urine.

DR. J. J. PUTNAM: Dr. Folson's case is especially valuable as increasing by one more the number of the instances of arsenic poisoning of—so to speak—domestic origin, where the disease appeared in a clearly recognizable form, instead of in the guise of general impairment of health, such as might have been due to other causes.

It will be remembered that Dr. E. G. Cutler reported a case of arsenical paralysis of this same type, only a few months ago, due apparently to poisonous tags, and Dr. F. C. Shattuck has just had a marked example of the same thing in his service at the Massachusetts General Hospital, which was fairly traceable to arsenical wall paper.

The number of physicians is constantly on the increase who have felt justified in referring more or less severe illnesses among their patients to this same cause, and it will not be long before the profession will be able to present a body of facts to the legislature that shall compel the passage of laws placing some sort of check on the wanton sale of poisons by persons wholly ignorant of the dangers to which their customers are to be exposed. The obstacle to this hitherto has been mainly that physicians themselves were, as a rule, in the dark as to the diagnosis of their cases.

The symptoms of acute arsenical poisoning have long been fairly clear; and we have known a good deal,

through such experiments as those of Vandrey, and through observations in therapeutics, of the effects of arsenic when pushed rapidly up to and beyond the limits of tolerance. But of the poisonous effects of minute doses, long continued and irregularly taken, without reference to the establishment of tolerance, and of the relative effects of arsenical compounds not used in medicine, we have known but little and we could know but little, because it is almost exclusively in cases of exposure to wall papers and fabrics that these conditions exist, and it has always seemed a sort of begging of the question to refer the observed effects to so mysterious a cause.

Fortunately, an amount of collateral evidence has been collected that places us in a much better position than heretofore to utilize our clinical data. In the first place, the researches of the chemical department of the college, both in Boston and Cambridge, and of chemists elsewhere, have disclosed the astonishing frequency with which arsenic is to be found in the urine, even when it would have been wholly unsuspected.

To speak only of the observations with which I am personally conversant, Dr. Worcester has now analyzed, at my request, about eighty urines, mainly from hospital patients, few of whom exhibited typical symptoms of poisoning, and has found arsenic in more than thirty per cent. If we transfer these proportions to the community, and make as liberal allowances as any one desires for accidents, we have the proof of the exposure of an immense number of persons from among whom other contributive causes, such as enfeebled local or general nutrition, and the unusual susceptibilities which we know to exist, should select the small proportion, but large aggregate of victims.

The familiar argument of the laymen that, in view of these facts we ought all to be poisoned, need only be mentioned to be dismissed. The same thing might be said with regard to every poison.

I have systematically canvassed the painters of the city, for example, as to the frequency of lead poisoning, and find but few who have ever seen it; yet every year brings to the hospitals men whose usefulness is had ruined by typical lead paralysis.

In investigating the clinical aspects of the question, however, conservative a position we may wish to take, there are certain well established facts which every one ought to bear in mind. Prominent among these are:

(1) That there are at least four or five distinct forms under which chronic arsenic poisoning may exclusively or mainly appear. Such are the mucous membrane forms, in their different varieties, leading even to pneumonia; the cutaneous form; the paralytic forms; the anæmic form; the intermittent febrile form; the form in which a single nerve or a few nerves are affected, causing neuralgia or herpes zoster. It causes irritation of the kidney, with albumen, casts and blood in the urine, and possibly acute nephritis; and, sometimes, special symptoms like tachycardia.

(2) While one person in a household is suffering from symptoms of this disease, another may be unaffected or even gaining in flesh and color; and even local diseases, such as neuritis, and an actual or apparent gain in general nutrition, seem not to be incompatible.

(3) Symptoms may long outlast exposure, and even flow with a future, so that paralysis, for example, could arise in a single day, need not make its appearance in one or two weeks or even longer. Correlative

to this is the fact that the electrical reaction may be altered before any paralysis has been noticed; and the same thing has been observed both clinically and experimentally with lead. Thus the guinea-pigs in whom Gombault found his segmental neuritis were said to run round, as lively as ever.

(4) Instead of indifference to the drug, a marked susceptibility to small doses may be developed by an attack of poisoning.

(5) Children (especially infants) possibly differ somewhat from adults in the character of their susceptibility to arsenic poisoning. In general they bear relatively large amounts of the drug, or at any rate this seems to be true of the children of an age to be treated for chorea. So far as the small number of facts at our command indicate, typical neuritis is uncommon among children as a result of either lead or arsenic poisoning. A number of such cases due to lead are, however, on record, and I have recently collected them for the *Cyclopedia of Children's Diseases*. I have also lately seen one child about a year old, in consultation with my brother, that was apparently suffering from arsenical neuritis. On the other hand, there are cases that seem to indicate that children may become extremely prostrated and anæmic from this cause without showing local symptoms.

(6) Recent observations show that elimination is far less rapid than was formerly supposed.

When we get beyond the recognized types of arsenic poisoning, the diagnosis becomes, of course, extremely difficult, and in part depends on the argument by exclusion, and on the effects of treatment.

Among the hospital patients to whom I refer, and in whose urine arsenic was found, symptoms of the following sorts have been noted: anæmia, optic neuritis, spastic paraplegia, persistent colic, and numbness of the hands and feet, and these are all symptoms which might fairly be attributed to the action of arsenic in small doses.

DR. CHARLES HARRINGTON: With regard to legislation on the subject of arsenic, it will be remembered that about five years ago an attempt was made to get a bill through the legislature not absolutely prohibiting arsenic in wall papers and fabrics, but establishing a limit. About the only persons who then appeared in its favor at the hearing of it were a number of the professors and instructors from Harvard College and its Medical School. We had, unfortunately, not such strong evidence as we now have as to the existence of chronic arsenical poisoning, proven by the presence of arsenic in the urine. We met a very strong antagonism in the legislature, and at the hearing which was held, many of the wall-paper men from New York and Boston, and several of the Lowell manufacturers were present in opposition. A professor of chemistry from New York testified in effect that arsenic was a harmless drug. The end of it was that the petition was almost laughed out of the House. Since that time our processes for detecting small amounts have been very much improved. Professor Sanger, now of the Naval Academy, improved very materially the process of detecting arsenic in the urine, and since the time of that hearing, when we had really no cases which we could back up by finding the arsenic in the system, I suppose it can be said that we have collected hundreds of proven cases, so that soon it seems to me it will be in order to go to the legislature with a good, strong professional backing.

DR. C. P. WORCESTER: In regard to the reliability of the test in the cases that Dr. Putnam has mentioned, I will say I was at first inclined to be very sceptical on finding indications of arsenic in so many urines, but I convinced myself in many ways that it was really arsenic. The materials used in the test have proved over and over again to be absolutely free from arsenic, and arsenic was not reported to be present in any case unless it was confirmed by secondary tests.

DR. F. C. SHATTUCK: Within a comparatively short time four cases of multiple neuritis, presumably due to arsenic, have come under my notice, and in addition to these two cases showing other forms of arsenical poisoning. One of those was a lady, in whom the trouble was caused by wall paper. One was a young woman who had had chorea, and had been treated by large doses of arsenic, the result being a very extensive arsenical neuritis with paralysis. Another was a lady who has been considered the subject of rheumatism for some years. She has lately come under my observation, and it seemed to me that she was suffering from a neuritis. The urine has just been examined by Dr. Wood, and found to contain a very large amount of arsenic. The source of the arsenic has not yet been ascertained. The other case, to which Dr. Putnam has alluded, had a very well-marked extensive peripheral neuritis. The source of the arsenic in this case also was from wall paper.

As to how long a period is required for the elimination of arsenic, Dr. Wood is now making investigations. I am furnishing him every day urine from certain patients of mine at the hospital, one of whom has taken arsenic for a considerable time; the other, a comparatively healthy person, received three minims of Fowler's solution three times a day for three days, and his urine has been sent every day since then for analysis. Dr. Wood is going to follow it up and see how long it takes to eliminate medicinal doses as well as these toxic doses. He will report undoubtedly upon that subject later.

DR. FOLSOM: As to the frequency of this affection, I have seen a very large number of cases. I reported this one to-night because the symptoms were exceptional. There was one point in which two of my patients were very much deceived, and I dare say many others have been in the same way. One lady completely refurnished her house with wall papers from one of the leading houses in Boston, which employs a chemist. She therefore thought she was getting safe papers. I think hers was one of the worst cases of arsenical paralysis I have seen. Dr. Wood found five of six samples of paper containing arsenic. The firm admitted the fact, but said that she had not asked with reference to that point. The same thing occurred in another instance.

EPIDEMIC OF ERGOTISM. — The *Lancet*, of February 21st, contains a short account of a serious epidemic of ergotism or "pernicious spasm," which occurred during the latter part of 1889 and the early months of 1890 in the province of Viatka in Eastern Russia. The number of persons attacked is given as 2,719, of whom 535, or nearly 20 per cent., died. Men, women, and children all suffered, especially the poorer classes, who, having no store of flour, had to use the product of the harvest of 1889 as soon as the corn was cut.

## THE BOSTON Medical and Surgical Journal.

THURSDAY, MARCH 19, 1891.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States, Canada and Mexico; \$6.50 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

### COMPARISON OF THE OCULAR TROUBLES IN LOCOMOTOR ATAXIA, MULTIPLE SCLEROSIS, AND HYSTERIA.

In a recent clinical lecture at the Salpêtrière, Charcot considered comparatively the ocular troubles occurring in tabes, multiple sclerosis, and hysteria.

Amblyopia with nacreous degeneration of the papilla is often the first symptom of locomotor ataxia, even preceding the motor inco-ordination, the diminution of the reflexes, the lightning pains, by many years.

Nystagmus, when not hereditary, has a symptomatic value almost as great in the diagnosis of disseminated sclerosis.

In tabes, paralyzes of the motor muscles of the globe of the eye are very frequent, especially paralysis of the muscles innervated by the *motores oculorum*. When in presence of the diplopia proper to paralysis of the third pair, one should always have in mind the probability of tabes. Paralysis of the abducens has also been witnessed in tabes, but very rarely.

In disseminated sclerosis, it is the abducens which is attacked in preference; paralysis of the *motores oculorum* is much less frequently seen.

Hysteria may sometimes engender strabismus by paralysis or by spasm; it may give rise to associated paralyzes, but never to nystagmus. In hysteria, there is also the lid-drop, and the ptosis is due, not to paralysis of the levator muscle, but to spasm of the orbicularis. We find, moreover, in hysteria, a symptom not met with in any other affection, namely, monocular diplopia, so well-studied by Parinaud. Diplopia is generally binocular, and is due to paralysis of the third pair or of the abducens.

The condition of the pupils in locomotor ataxia is peculiar; they are generally contracted. This is especially noticeable in patients who have blue eyes. Sometimes the pupils are unequal; one is moderately dilated, the other is small. This inequality of the pupils is only seen in two diseases, general paralysis and locomotor ataxia. There is another sign equally common to these two affections, that is, what is design-

nated under the name of the Argyll-Robertson pupil. If near to one of these pupils when moderately dilated you hold a light, the pupil does not contract; if you place the patient in a dark room, you will observe that the pupils fail to dilate. The pupils do not contract under the influence of light, while under the influence of efforts of accommodation, they react as in the normal state.

Nothing of this kind is observed in multiple sclerosis. Generally in this affection there is nothing special to remark in reference to the pupil.

In tabes, one may frequently witness sclerosis of the optic nerve; the ophthalmoscopic observation is like an autopsy on the living subject. The retinal vessels are seen to be small and atrophied; the nerve has a pearly-pale, anemic aspect (nauseous papilla); these appearances are always of unfavorable augury, and the patient who presents them will be surely tabetic and blind in the course of a year or two.

In multiple sclerosis, there may be lesions of the fundus oculi, but both eyes are not irretrievably affected, and the amblyopia lasts only four or five months; at the end of this time, there is always an amelioration. Ulthoff, out of one hundred cases, noticed but one case of blindness. In this form of sclerosis, the contours of the papilla are less sharp than in the normal state; there is a sort of cloudy exudation, the vessels are atrophied; the general aspect is that of a dull, yellowish white in extreme cases.

In hysteria, there may be amblyopia, even complete amaurosis, but the modifications of the papilla noted in amaurosis are never witnessed; the functional troubles may be very pronounced, but are sure to disappear. Hysteria almost always causes a contraction of the visual field, which is concentric instead of being irregular, as is the case in locomotor ataxia. In the latter disease, the campimetric image presents notches and indentations; at the same time, there supervenes a dyschromatopsia which has quite peculiar characters. An individual, who is not affected with congenital Daltonism, will affirm that the pantaloons of the foot soldiers appear to him black; the trees, instead of being green, are to him of a grayish black color; at the same time vision for yellow and blue is still perfectly good. By and by the vision for yellow and blue ceases in its turn, the visual field contracts more and more, till white itself is no longer perceived.

In hysteria, dyschromatopsia is much less frequent than in tabes, and when it does exist, the colors do not disappear in the same order. It is first the blue which is no longer perceived, then the yellow, then the other colors successively, with the exception of red, which persists alone during a very long time.

In disseminated sclerosis, there is nothing to note respecting the visual field or the perception of colors.

The President of the French Republic has conferred on Professor von Helmholtz the Grand Cross of the Legion of Honor. This is said to be the first time since 1870 that this distinction has been conferred on a German.

# REPORT OF THE MASSACHUSETTS GENERAL HOSPITAL AND McLEAN ASYLUM FOR THE YEAR 1890.

THE trustees of the Massachusetts General Hospital and McLean Asylum, in issuing their seventy-seventh annual report, state that the past hospital year, though comparatively uneventful, has been marked by much quiet usefulness—a usefulness which has been restricted, however, by limited resources and they avail themselves of this opportunity to lay the more pressing wants before present and possible benefactors.

The summary of expenditures for patients, over and above receipts from them was:

Hospital	\$98,289.40
Asylum	13,769.98
Convalescent Home	8,329.20
	\$120,388.58

And these were met by income of Funds:

Hospital	\$97,050.08
Asylum	11,025.60
Convalescent Home	8,491.68
	\$116,567.36

And by drawing from the General Fund, or capital.	\$3,781.22
	\$120,388.58

The deficit in 1889 was much larger, having amounted to \$26,659.04. This decided change for the better leads the trustees to hope that the current year may witness, for the first time in a long period, the reduction of expenses to the limit of income.

The income of free-bed funds and free-bed annual subscriptions is reported as still claiming anxious consideration and co-operation; both have increased during the year, but the increase should become much greater to secure the service of free-beds from interruption. The actual needs of the hospital, in addition to the above, are stated to be: (1) A ward for contagious diseases, not for the admission of such diseases, but for the isolation of cases developing in the hospital; (2) An addition to the out-patient department; (3) A house for the resident physician and his family; (4) Funds for rebuilding the McLean Asylum on the estate in the country at Waverly, purchased fifteen years ago for that purpose. The indications then existing for removal make themselves felt more and more forcibly with every year's delay.

From the report of the resident physician of the hospital we learn that the number of patients in the hospital January 1, 1891, was 191; the whole number treated during the year was 3,395; of those discharged 1,149 were medical, 2,246 surgical, 2,031 were male and 1,364 were female. It will be noticed that the surgical patients, as in former years, largely predominate, being nearly two to one.

The proportion of deaths to whole number of results was 8.18 per cent. The proportion of ward beds occupied by free patients was 77 per cent., by paying patients 23 per cent. The average number of free patients was 17.4, and of these 80 were Americans and 94 were foreigners. The average time of paying patients was 2.14 weeks, and that of free patients 3.55

weeks. The average cost per patient per week in 1889 was \$13.64, in 1890 \$12.41.

From the report of the superintendent of the McLeau Asylum it is learned, that,

There were two hundred and ninety-seven cases treated during the year, representing two hundred and ninety-one persons. Of the one hundred and twenty persons admitted during the year, seventy-five were regarded as recent cases, and forty-five as chronic, or incurable.

Eighty-three persons, thirty-six men and forty-seven women, had never been in any hospital. Of the remaining thirty-seven persons, twenty-four, fourteen men and ten women, were admitted for the second time; eight persons, five men and three women, for the third time; three persons, two men and one woman, for the fourth time; one man for the fifth time; and one man for the twenty-fifth and twenty-sixth times.

Of the forty-three persons discharged recovered, thirty had never before been inmates of any hospital; and, of the remaining thirteen persons, ten had been in this asylum, two in private asylums in this State, and one in an asylum in another State. These thirteen had previously made forty-four recoveries.

The average duration of illness from the beginning of attack in all cases recovered was 8.31 months, and the average duration of their residence in the asylum was 5.17 months.

The percentage of recoveries on all admissions, of persons accounted as insane, for the year 1890, was 36.97.

The voluntary cases admitted during the year numbered fifty-eight. These represented fifty-five persons, — thirty-four men and twenty-one women. Of these, twenty-nine were cases of melancholia, five of mania, two of "fixed ideas," three of delusional insanity, four of secondary dementia, one each of paralytic, epileptic, and toxic insanity, five of general paralysis, and four were not insane. Of these fifty-five persons, three were committed after entering the asylum as voluntary cases, and two were twice admitted as voluntary cases. The fifty-eight voluntary cases admitted during the year with twenty-nine such cases remaining from previous years furnished seventeen recoveries. Thus the voluntary patients have yielded 29.3 per cent. of recoveries on the admissions of that class for 1890, thus furnishing less than their due proportion of all the recoveries.

The voluntary system continues to give accumulating evidence of its value to those who avail themselves of it, and of its ameliorating influence upon the conditions of the asylum.

The general results of the eighth year since the formal organization of the asylum training school for nurses is reported as satisfactory.

The trustees of the hospital were approached a year ago by a committee of the medical faculty of Harvard University with regard to the establishment of a clinical ward and lecture-room at the hospital, to be under the hospital administration, but affording continuous service to clinical teachers at the school and giving a voice in the nomination of appointees to the medical faculty. The trustees report that they were unable to accept the project of the committee on account of its being to some extent at variance with their usages, and it has been dropped for the present. As a temporary substitute, three months for the year were added to the four months' service of the visiting physician who is the professor of clinical medicine — one month being surrendered to him by the courtesy of each of three associates on the staff. Such an arrangement must necessarily be regarded as temporary and provisional, and can hardly satisfy the legitimate aspirations of the Medical School.

The following preamble and votes show the action of the trustees of the hospital upon the death of Dr. Henry J. Bigelow last October:

The brilliant contributions of the late Dr. Henry J. Bigelow to surgical science entitle him to rank with the great surgeons

of the world, and it is especially appropriate that the Massachusetts General Hospital should perpetuate the remembrance of his service of forty years upon its surgical staff, a service which contributed so much to the relief of human suffering, and gave the hospital a wide-spread renown. It was here, in 1846, that, with enthusiasm and courage, he took a leading part in the first demonstration of the anæsthetic property of sulphuric ether, a discovery which later made possible his method of reducing the dislocation of the hip-joint, and again his ingenious treatment by litholapaxy. It is no exaggeration to say that these improvements in surgery have made his name illustrious among the benefactors of mankind.

It is therefore, *Voted*: (1) That the operating-room of the hospital be hereafter designated as "The Henry J. Bigelow Operating Theatre," and the resident physician is instructed to have this name inscribed upon its walls. (2) That the Secretary be instructed to communicate the foregoing vote to Dr. William S. Bigelow, with the request that he will allow the trustees to have made a copy of one of the portraits of his father, to be placed in the Henry J. Bigelow Operating Theatre, in order that the pupils of the medical school in coming years may be stimulated by his achievements to a more thorough devotion to the noble profession which they have chosen to make their own.

## MEDICAL NOTES.

**SMALL-POX**, though still in several Texan towns, is rapidly on the decline. It is stated that the minister of the interior of Mexico has issued a circular to the governors of the several Mexican States, directing them to enforce compulsory vaccination.

**THE COINING OF NEW WORDS.** — An esteemed New York contemporary discusses, in a manner which would seem to indicate that he has the purity of the English language at heart, the proper formation of some new words which have become necessary on account of the birth of some new ideas; but, alas! in the very next column, in reviving an old idea (or, more properly speaking, what our contemporary's ancestors considered an old bit of humor) a word appears which hardly does credit either to his English or to his Latin. Whatever virtue may be attached to the knowledge of the proper way of pronouncing the word "plithisis," it is surely not sufficient to excuse the forcing into English of such a combination of Latin and Greek as appears in "leguminophagus." Even if this could be explained by the cosmopolitan character of the largest city on the continent, there is surely no excuse for the use of a word which represents such a variety of vegetables as legumen — if, as may be the case, beans are meant.

**"THOKA-LOSI."** — Dr. Bolton G. Corney, chief medical officer of Fiji, has described in the "Transactions of the Australasian Association for the Advancement of Science," for 1890, a mutilation practised by Fijians. A bough made from the twig of the tree called by the natives *loslosi* is passed down the urethra as far as the membranous portion, and an incision about an inch in length is made down upon it with a rude knife formed from a sharp shell, a slip of bamboo, or, where such a civilized implement can be obtained, with a piece of broken glass bottle. The operation is called *thoka-losi* — *losi*-piercing. It does not appear to be performed as a religious rite, and Dr. Corney does not believe that it is intended to render

the man sterile, which has been asserted to be the object of a similiar Australian mutilation. On the contrary, it would seem to be used merely as a method of treating such painful affections as rheumatism, catarrhal fever, pneumonia, and pleurisy, under the idea that, by incising a dependent portion of the trunk, relief will be given to the accumulation of blood which is supposed to have occurred. This view appears to be confirmed by the existence of another form of mutilation termed *targa-ngalengale*; it consists in incising the urethra from the meatus to a point just behind the frænum preputii, severing the artery; after this, as much as half-a-pint of blood may be lost, so that the operation is evidently a primitive kind of venesection. Dr. Corney states that after the graver mutilation produced by *thoka-losi* the wound soon heals, and perineal fissure seldom or never results.

#### MIDWIVES IN THE TIME OF QUEEN ELIZABETH.

—The following curious oath is recorded in the *Medical Press* as the condition upon which Mistress Eleonor Pead received a licence from the Archbishop of Canterbury, in 1567, to practise midwifery:—"I, Eleonor Pead, admitted to the office and occupation of a midwife, make oath that I will faithfully and diligently exercise the said office according to such cunning and knowledge as God has given me, and that I will be ready to help and aid as well poor as rich women being in labour and travail of child, and will always be ready both to poor and rich in exercising and executing of my said office. Also, I will not permit or suffer that any woman being in labour or travail shall name any other to be the father of her child than only he who is the right and true father thereof; and that I will not suffer any other body's child to be set, brought, or laid before any woman delivered of child in the place of her natural child, so far forth as I can know and understand. Also I will not use any kind of sorcery or incantation in the time of the travail of any woman; and that I will not destroy the child born of any woman, nor cut nor pull off the head thereof, or otherwise dismember or hurt the same, or suffer it to be hurt or dismembered by any manner of way or means. Also, that at the ministration of the sacrament of baptism in the time of necessity I will use apt and accustomed words of the same sacrament—that is to say, these words following, or the like in effect: *I christen thee in the name of the Father, the Son, and the Holy Ghost*, and none other profane words, and that in such time of necessity, in baptising any infant born, and pouring water upon the head of the same infant, I will use pure and clean water, and not any rose or damask water, or water made of any confection or mixture; and that I will certify the curate of the parish church of every such baptising."

Dows in Kentucky, to avoid being buried alive, it is said that a friend approaches the corpse, and in a low whisper into the ear of the corpse, the friend says:—"Let's take a drink." If there is no response, the funeral proceed.

#### BOSTON AND NEW ENGLAND.

**CONTINUATION OF ARSENIC HEARING** before the Committee on Public Health. Henry Saltonstall, Treasurer of the Pacific Mills, said that a law prohibiting the use of arsenic would kill itself. Its use within a danger limit should be allowed, and medical testimony should fix that limit. The Pacific, Merri-mac, and Hamilton Mills would co-operate in every way to support the law, and would guarantee their goods as free from arsenic, but the law should reach in some way goods from outside this State. Most of the goods here manufactured are sold outside of Massachusetts. Dr. F. H. Brown showed the dangerous effects from exposure to arsenic. Counsel for the remonstrants submitted Dr. Brown to a very searching cross-examination. Several others, both physicians and chemists were heard, their evidence being cumulative as to the present dangers from arsenic.

**CIGARS FOR CATARRH.**—An interesting case was recently tried in a Boston municipal court, under the law preventing druggists from selling cigars on Sunday, for other than medicinal purposes. The defendant was led to believe that the purchaser had catarrh, and was suffering from bronchial catarrh and lung trouble, that he was an inveterate smoker, and really needed the cigars as a drug. The judge read the law in regard to the sale of cigars, which stated that they might be sold as a drug, and as he considered that they were such in this case he accordingly ordered that the case be dismissed.

**EMBALMING.**—The Judiciary Committee of the Massachusetts Legislature, before which a petition was brought for an order providing that no body shall be embalmed until a certificate of the cause of death has been filed, have given the petitioners leave to withdraw. We have since learned that one of the members of the committee is treasurer of an embalming company. The stalling of this measure in the committee is to be regretted. The practice of embalming as now often carried out by undertakers not only interferes with autopsies in medico-legal cases but also with those desired for purposes of diagnosis.

**THE NEW LIBRARY BUILDING AT THE BOSTON CITY HOSPITAL** was opened to the medical fraternity last Thursday evening, March 12th. The trustees of the hospital invited the members of the staffs of other Boston hospitals to a reception that evening. A very large, handsome, well-ventilated, central room is provided for the library and reception-room, with several smaller adjoining rooms for journals, for reading-rooms and other purposes. Much satisfaction was expressed at the results accomplished by the trustees.

#### NEW YORK.

**THE UNITED CHARITIES BUILDING.**—Mr. John S. Kennedy, a well-known retired banker, has announced his intention of erecting a large building at the corner of Fourth Avenue and 22d Street as a sort

of headquarters for charitable work among the poor of the city. The proposed building is to be called the United Charities Building, and will provide offices at a nominal rental for the Charity Organization Society, the Association for Improving the Condition of the Poor, the Children's Aid Society, and the New York City Mission and Tract Society. It will also provide offices at a moderate rental for other benevolent institutions, and portions of it may be rented for other purposes. It is his expectation that the rentals will more than meet all expenses of maintenance. It is estimated that the cost of the land and the erection of the new building will amount to about \$400,000.

#### HOSPITAL SATURDAY AND SUNDAY ASSOCIATION.

—The Distributing Committee of this Association have made the annual apportionment of the money collected for the hospitals. The amount collected was \$58,297, and of this \$49,000 was distributed to the various institutions represented in the Association in accordance with the number of days of treatment given to free patients in each during the year 1890. Among others: Mount Sinai Hospital, received \$6,789; St. Luke's Hospital, \$5,930; Montefiore Home for Chronic Invalids, \$5,020; German Hospital, \$4,890; Hospital for Ruptured and Crippled, \$4,677; St. Mary's Free Hospital for Children, \$2,394; Home for Incurables, \$2,276.

#### BEQUESTS UNDER THE FAYERWEATHER WILL.

The noted Fayerweather will contest has been brought to a close, and as a result an enormous amount is to be distributed among institutions of learning and hospitals. Yale University receives the largest sum, \$450,000, and the hospitals which came in for a share are the following: Woman's Hospital, \$210,000; St. Luke's Hospital, Presbyterian Hospital, and Manhattan Eye and Ear Hospital, each \$50,000; Mount Sinai Hospital, New York Eye and Ear Infirmary, Manhattan Hospital, Montefiore Home for Chronic Invalids, New York Cancer Hospital, and the Methodist Hospital, Brooklyn, each \$25,000.

**BELLEVUE HOSPITAL TRAINING SCHOOL FOR MALE NURSES**, which was established two years ago through the liberality of Mr. D. O. Mills, graduated on March 11th the first class (17 in number) to complete the course of instruction and practical work. Since the school was opened there have been in attendance 115 pupils. At present the number is 43, and applications for admission are largely in excess of this.

#### NEW YORK COLLEGE OF VETERINARY SURGEONS.

—The thirty-fourth annual commencement of this College took place March 4th, when the degree of V. S. was conferred upon 36 graduates.

**LONG ISLAND COLLEGE HOSPITAL.** — At the commencement of this Medical School held March 11th, there was a graduating class of 82, and Dr. T. Gailhard Thomas, of New York, delivered the principal address.

## Miscellany.

### AN APPARATUS FOR THE CORRECTION OF TALIPES EQUINO VARUS.

MR. DANE's apparatus for correcting talipes equino varus without tenotomy is shown in the following illustration.

A description of this apparatus will be found on page 260 of the JOURNAL of March 12th.

### FRÄNKEL'S OPINION OF KOCH'S METHOD.

At the meeting of the Berliner Medizinische Gesellschaft on February 25th, the discussion on Fränkel's address, came to an end. Professor Fränkel, in replying, said: "I am of opinion that tuberculin exercises a direct influence on those parts of the body where tubercle bacilli exist, and where they have caused changes to take place; and that this influence consists in a corrosive action with supervening necrosis. Thus I uphold my opinion that tuberculin is a specific for tuberculosis. If this be so, whence comes it that its therapeutic action is so much called in question? I think the answer is: because tuberculin (1) does not affect the tubercle bacilli, and (2) because it has some untoward by-effects." He carefully weighed the pros and cons of the tuberculin treatment, such as his own experience had made known to him, and said that though fully alive to the possible dangers of the injections, he had found the curative effect in many cases so marked, so much greater than he had yet observed to follow any other therapeutic method, that in his opinion the physician, after having carefully and conscientiously selected suitable cases, must calmly face the danger, in the same way as the surgeon does day after day.

### THE RELATION OF DISEASES OF ANIMALS TO THOSE OF MAN.

A PROMINENT place will be assigned, in the discussions of the International Congress of Hygiene, which is to be held in London next August,<sup>2</sup> to the question of how far the diseases of animals are communicable to man, and *vice versa*. The subject has been prominent lately in consequence of Koch's recent discoveries, and the appointment of a Royal Commission to investigate the subject of tuberculosis. The Organizing Com-

<sup>1</sup> British Medical Journal, February 28.

<sup>2</sup> See page 272 of the Journal of March 12.

mittee of the Hygienic Congress have recognized the importance of the question by setting apart a special section for its discussion, and have been successful in associating with the section gentlemen of high authority in the medical, veterinary, and agricultural world. The section proposes to consider, amongst other subjects, the infectious, contagious, parasitic, and other diseases communicable from animals to man, and *vice versa*; the methods of the propagation of diseases affecting mankind by means of animals and animal products; the infection of meat, milk, and other comestibles; and the restrictions to be placed upon the sale of infected food and movement of infected animals. On each of these questions papers will be obtained from acknowledged authorities as the basis of the debates of the section, which promise, therefore, to be of very great interest and value.

### IMPACTION OF ARTIFICIAL TEETH IN THE LARYNX.

MR. LENNOX BROWNE records a case of unrecognized impaction of artificial teeth for twenty-two months, with successful removal.<sup>1</sup> The patient was a lady, about thirty-five years of age, who had become very much emaciated. It had been considered by two gentlemen, who had used the laryngoscope, to be merely a question of diagnosis between cancer of the larynx and laryngeal phthisis. On looking down the throat with the mirror, Mr. Browne saw impacted across the larynx, fixed in each hyoid fossa, what he diagnosed to be a plate of artificial teeth. It apparently divided the larynx into two equal halves. Chloroform was given for the purpose of allaying spasm, but not to insensibility, and taking a pair of rectangular forceps he lifted the plate up on the left side; this was followed by a violent paroxysm of dyspnoea. On pushing the chloroform a little, he was enabled to withdraw the foreign body by his finger passed far down. The after-treatment consisted merely in the application of the cold coil. There was some traumatic perichondritis which impeded the left vocal cord, but the patient made a good recovery. The teeth had been lost during an attack of vomiting and dyspnoea twenty-two months previously.

### ICHTHYOL AND ITS PREPARATIONS.<sup>2</sup>

IS a communication to the Société de Médecine Pratique de Paris, Gillet de Grandmont reviews the uses and preparations of this drug.

Ichthyol itself, and especially the ichthyolates of ammonium, sodium, lithium and zinc, have been advantageously employed, both externally and internally. As a whole, ichthyol has been found to be a powerful antiphlogistic remedy. Unna has employed it particularly in skin diseases, and internally in doses of from fifteen to sixty grains. Patients, under its use, have increased in bodily weight. Zuelzer, of Berlin, has used the ichthyolates with good results in the treatment of vesical catarrh, chronic haemorrhoids, peritonitis, pyonephritis, uterine affections, and in Bright's disease. Grandmont himself reports a case of chronic cystitis, with albuminuria, in which the internal use of ichthyolate of ammonium stopped the elimination of albumen.

This preparation, in the form of solution in water or glycerine, or as an ointment, is especially employed in surgical practice, owing to its solvent action and its power of constricting the capillaries. Nussbaum affirms to have obtained good results in the treatment of erysipelas, and even in diseases of rheumatic and gonty origin. The sulpho-ichthyolate of ammonium may be given in daily doses of from fifteen to sixty grains for adults, and for children in from three to seven and a half grains.

For external use a watery solution of any of the ichthyolates may be employed in the strength of ten per cent., or in the form of an ointment, twenty-five to thirty per cent.

### THE INFLUENCE OF TOBACCO ON THE PROCESS OF DIGESTION.

YDAN-POUCHKINE<sup>1</sup> made a series of careful experiments on seven persons in good health, but who were not accustomed to tobacco. His results were as follows: Tobacco increases the quantity of the gastric juice, but diminishes its acidity. The amount of free hydrochloric acid is decreased, and consequently the digestive power of the gastric juice. Its peptonizing power is also diminished. These effects last for a certain length of time. On the other hand the movements of the stomach, and its power of absorbing are increased. Tobacco has no effect on the acidity of the urine.

### THE GERMICIDAL PROPERTIES OF BLOOD.

VON FODOR, who has already contributed some useful papers, publishes in the *Centrablatt für Bakteriologie und Parasitenkunde*, Vol. vii., No. 24, some further experiments which he has made, especially directed to ascertain under what conditions the germicidal properties of the blood are at their highest, and in what way the composition of the blood affected these properties.<sup>2</sup> The first series of researches had reference to the composition of the blood, and proved, in the first place, that arterial blood has a more destructive action on the bacteria than venous, and also that fresh blood has a more powerful action than that which has been shed for some time. Again, the germicidal power of the blood was weakened in an atmosphere consisting entirely of oxygen or carbonic acid; on the other hand, the removal of gases from the blood had no appreciable influence. The blood of rabbits, which had been poisoned by carbonic acid gas, was not fatal to the bacteria. Some interesting results were obtained in reference to the temperature of the blood. From these it would seem that the germicidal power of the blood increased with the rise of temperature, reaching its maximum at 38° to 40° C., and then again gradually diminishing. The author mentions that the individual predisposition of any animal to an infectious disease seemed to stand in direct relationship with the germicidal power of its blood. The second series of researches was directed to the influence of drugs on the power of the blood to destroy germs. Hydrochloric acid had no effect. After treatment of tartaric acid a marked decrease was noticed, and the same result was produced by quinine. Common salt and

<sup>1</sup> *Vierteljahr.* No. 48, 1890.

<sup>2</sup> *Lancet*, February 21.

carbonate of ammonium caused a slight increase of the power, the phosphate of sodium a more marked effect, whilst the carbonates of sodium and potassium produced a very remarkable increase. From the experiments the author concluded that any drugs which cause increased alkalinity of the blood considerably raised the resisting power of the organism against the invasion of bacteria. The third of this series of experiments corroborated this supposition. Of eight rabbits inoculated with anthrax all died, whilst of nineteen which had been previously injected with soda solution only three died, thus proving the efficacy of the alkalization of the organism. Of the remaining sixteen cases a few were affected at a later date, but the majority remained perfectly free from disease.

### PRESCRIPTIONS.

**ROTTER'S ANTISEPTIC.**—Rotter<sup>1</sup> united in one solution a large number of antiseptics, each in a very small dose, hoping that their antiseptic effects would be cumulative, while their toxic effects would not.

R Corrosive sublimate . . . . .	gr. $\frac{1}{2}$
Common salt . . . . .	gr. lv.
Carbolic acid . . . . .	gr. xxx.
Chloride of zinc . . . . .	aa gr. lxxxv.
Sulpho-carbolic acid of zinc } . . . . .	gr. xlv.
Boric acid . . . . .	gr. ix.
Salicylic acid . . . . .	gr. ix.
Thymol . . . . .	aa gr. iss.
Citric acid } . . . . .	M.

The whole to be dissolved in a liter of water, for compresses, irrigation of wounds, etc.

**FISSED NIPPLE.**—Hirst<sup>2</sup> has found that excellent results can be secured in bad cases by the following application:

R Bismuth subnitratiss } . . . . .	aa 3 j.
Olei ricini } . . . . .	M.

Before application the nipple and surrounding skin should be carefully cleansed, and the ointment should be smeared on plentifully.

**LACTIC ACID FOR NASAL DIPHThERIA.**—Ranlin<sup>3</sup> recommends the following treatment. The membrane is detached by means of antiseptic irrigation, and the raw surfaces are covered by the following:

R Lactic acid . . . . .	grs. xxx.
Carbolic acid . . . . .	grs. xlv.
Pure glycerin . . . . .	3 j.

### Correspondence.

#### REPEAL OF CHARTER OF MEDICAL AND SURGICAL COLLEGE OF NEW JERSEY.

NEW JERSEY STATE BOARD OF MEDICAL EXAMINERS.  
JERSEY CITY, March 11, 1891.

MR. EDITOR:—It affords me much pleasure to inform you that our bill repealing the charter of the Medical and Surgical College of New Jersey, has been passed by the Legislature and approved by Governor Abbott. It is hardly necessary for me to say that this Board feels that it has, in the first year of its existence, done something towards the purification of the medical profession, not only in this State, but throughout its sister States.

Yours very truly,

WILLIAM PERRY WATSON, Secretary.

### METEOROLOGICAL RECORD.

For the week ending March 7, in Boston, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Date.	Barometer.	Thermometer.	Relative humidity.	Direction of wind.	Velocity of wind.	Wet't'r.	Rainfall in inches.

### RECORD OF MORTALITY

FOR THE WEEK ENDING SATURDAY, MARCH 7, 1891.

Cities.	Estimated population for 1890.	Reported deaths in each.	Deaths under five years.	Percentage of deaths from infectious diseases.	Acute lung diseases.	Measles.	Diphtheria and croup.	Scarlet fever.
New York . . . . .	1,622,257	735	291	17.55	18.36	2.04	6.53	3.26
Chicago . . . . .	1,100,000	491	208	13.03	22.40	1.22	2.85	2.24
Philadelphia . . . . .	1,064,277	378	123	12.47	8.73	.26	5.81	1.58
Brooklyn . . . . .	852,467	368	144	14.13	20.65	1.35	6.25	3.80
St. Louis . . . . .	550,000	—	—	—	—	—	—	—
Baltimore . . . . .	376,843	—	—	—	—	—	—	—

New York and Washington 3 each, Chicago, Philadelphia, New York and Boston 2 each, Brooklyn 1. From malarial fever New York and Brooklyn 2 each, Nashville 1.

In the twenty-eight greater towns of England and Wales with an estimated population of 10,010,426, for the week ending February 28th, the death-rate was 24.1. Deaths reported 4,820; acute diseases of the respiratory organs (London) 685, measles 150, whooping-cough 139, diphtheria 52, diarrhoea 37, scarlet fever 30, fever 23.

The death-rates ranged from 13.8 in Plymouth to 38.9 in Blackburn, Birmingham 25.2, Bradford 19.9, Leeds 28.3, Liverpool 22.7, London 23.7, Manchester 27.0, Newcastle-on-Tyne 23.1, Sheffield 24.0, Sunderland 26.7.

In Edinburgh 24.6, Glasgow 27.9, Dublin 29.4.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 7, 1891, TO MARCH 13, 1891.

By direction of the Secretary of War, leave of absence for two months, on surgeon's certificate of disability, is granted Major SAMUEL HORTON, surgeon. S. O. 49, Par. 7, A. G. O., Washington, D. C., February 4, 1891.

By direction of the Acting Secretary of War, Captain HENRY I. KAYMOND, assistant surgeon, is relieved from duty at Newport Barracks, Ky., and assigned to duty at Fort Thomas, Ky., reporting in person to the commanding officer, Fort Thomas, and by letter to the commanding general, Division of the Atlantic. S. O. 54, Par. 18, A. G. O., Washington, March 10, 1891.

By direction of the Secretary of War, a board of medical officers, to consist of: Colonel EDWARD P. VOLLMER, chief medical purveyor; Lieutenant-Colonel DALLAS RACHE, surgeon; Major ALFRED C. GIBARD, surgeon; and Captain CHARLES M. GARDY, assistant surgeon, is constituted to meet in New York City, on March 18, 1891, or as soon thereafter as practicable, for the examination of candidates for admission into the medical corps of the army, and such other business as the surgeon general may desire to bring before it. S. O. 52, Par. 18, A. G. O., Washington, D. C., March 7, 1891.

#### RETIREMENTS.

Lieutenant-Colonel BLUNSWOGE E. FRYER, assistant medical purveyor, February 24, 1891.

Captain JAMES A. FINLEY, assistant surgeon, having been found by an Army Retiring Board incapacitated for active service on account of disability, which is not the result of any incident of service, is, by direction of the President, wholly retired from the service this date, under the provisions of sections 1,252 and 1,275, Revised Statutes, and his name will be henceforward omitted from the Army Register. S. O. 54, Par. 2, A. G. O., Washington, March 10, 1891.

#### PROMOTIONS.

Major CHARLES R. GREENBLATT to be lieutenant-colonel and assistant medical purveyor, February 24, 1891. Captain CHARLES K. WINNA, assistant surgeon, to be major and surgeon, February 22, 1891. Captain TIMOTHY E. WILCOX, assistant surgeon, to be major and surgeon, February 24, 1891. Captain FIELD C. MINSWORTH, assistant surgeon, to be major and surgeon, February 27, 1891. Captain VALERY HAYARD, assistant surgeon, to be major and surgeon, February 27, 1891.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING MARCH 11, 1891.

G. W. KILL, passed assistant surgeon, from New York Hospital, and to the "Lancaster."

J. H. NORTON, druggist, assistant surgeon, detached from "Lancaster," and was ordered.

G. I. SMITH, assistant surgeon, from the "Independence," and to the "Medican."

GEORGE A. DUNN, assistant surgeon, from the "Medican," and to the "Independence," in charge of insane patients.

#### MEDICAL REGISTER FOR NEW ENGLAND.

THE MEDICAL REGISTER for New England asks for the names of all persons interested in the publication, by the Committee on the Registration of Facts relating to organizations, and is hereby requested to send him at once a copy of the REGISTER, now in press, and additional facts of interest, and to be taken into consideration. About four hundred hospitals, hospitals, schools and other organizations are to be included, more than three thousand individual records must be included. The REGISTER will probably be published in May.

#### SOCIETY NOTICES.

**BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.**—A regular meeting of the Society will be held on Monday, March 23, 1891, at the Medical Library, 19 Boylston Place, at 8 o'clock P. M.

Readers: Dr. J. L. Putnam, "The Pathology and Treatment of Neuralgia of the Fifth Pair." Illustrated with Pathological Specimens. Dr. C. J. Blake, "Otagia."

G. G. SEARS, M.D., Secretary.

**CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.**—The second triennial meeting will be held in Washington, D. C., on September 22, 23, 24 and 25, 1891. The preliminary programme of subjects for report and discussion is as follows:

*Tuesday Afternoon*, September 22d, at 3 o'clock. Conditions Underlying the Infection of Wounds, Including a Discussion of Disinfection with Reference to Treatment of Wounds, of the Relation of Bacteria to Suppuration, of the Resistance of Tissues to the Multiplication of Bacteria, and of the Effects of Antiseptic Agents on Wounds. Referee, Dr. William H. Welch, of Baltimore. Professor of Pathology in Johns Hopkins University. Co-Referee, Dr. Roswell Park, of Buffalo, Professor of Surgery in the Buffalo Medical College. The discussion will be adjourned, if necessary, until Friday afternoon.

*Wednesday Afternoon*, September 23d, at 3 o'clock. The Late Manifestations of Syphilis. Referee, Dr. Phineas S. Conner, of Cincinnati, Professor of Surgery in the Medical College of Ohio; Co-Referee, Dr. Abner Post, of Boston, Instructor in Venereal Diseases and Syphilis in Harvard University.

*Wednesday Evening*, September 23d, at 8 o'clock. The President's Address. To be followed by a reception.

*Thursday Afternoon*, September 24th, at 3 o'clock. Fibroid Processes (Chronic Interstitial Inflammation, Sclerosis); their Pathology and Etiology, with Special Reference to the Influence of Diathesis and Heredity. Referee, Dr. Alfred L. Loomis, of New York City, Professor of Pathology and the Practice of Medicine in the University of the City of New York; Co-Referee, Dr. William Osler, of Baltimore, Professor of Medicine in Johns Hopkins University.

*Friday Afternoon*, September 25th, at 3 o'clock. If necessary, the discussion on the Conditions Underlying the Infection of Wounds, etc., will be resumed.

S. WEIR MITCHELL, M.D., President.

WILLIAM H. CARMALT, M.D., Sec'y, New Haven, Conn.

#### DEATHS.

WARREN JACOB WHITNEY, M.D., M.M.S.S., died in Dorchester, March 11th, aged eighty years.

ABEL C. LIVERMORE, M.D., M.M.S.S., of Stow, died March 15th, aged sixty-eight. He was struck by a train while crossing a railroad track, and died within an hour.

#### BOOKS AND PAMPHLETS RECEIVED.

Transactions of the Iowa State Medical Society for the Year 1890.

Abdominal Surgery. Gynecological Memoranda. By John R. Haynes, M.D. Reprints.

A New Operation for Spasmodic Wry-Neck. By W. W. Keen, M.D., Philadelphia, Pa. Reprint, 1891.

Prevention and Cure of Disease. By G. P. Conn, A.M., M.D., President State Board of Health, Concord, N. H. Reprint, 1891.

Annual Report on Laws Regulating Medical Practice. By Richard J. Dugglison, A.M., M.D., Secretary of the Academy. Reprint, 1890.

Report of the Trustees of the Rhode Island Hospital, presented to the Corporation at its Twenty-seventh Annual Meeting, November 12, 1890.

The Barbarity of Circumcision as a Remedy for Congenital Abnormality. By Herbert Snow, M.D., etc. London; J. & A. Churchill, 1890.

The Relation of Life Insurance to Inebriety. By T. D. Crothers, M.D., Superintendent Walnut Lodge Hospital, Hartford, Conn. Reprint, 1891.

Quiz-Compend. A Compend of Gynecology. By Henry Morris, M.D., with forty-five illustrations. Philadelphia; P. Blakiston, Son & Co. 1891.

Annual Report of the Health Department of the City of Baltimore to the Mayor and City Council of Baltimore, for the Fiscal Year ending December 31, 1890.

A Case of Intra-cranial Neoplasm with Localizing Eye Symptoms: Position of Tumor Verified at Autopsy. By Charles A. Oliver, M.D., of Philadelphia. Reprint, 1891.

Rupture of the Membrana Tympani by Injection of Warm Water into the Auditory Canal for the Removal of Impacted Cerumen. By S. Latimer Phillips, M.D., of Savannah, Ga.

**Address.****REGULATION OF THE PRACTICE OF MEDICINE IN RHODE ISLAND.<sup>1</sup>**

BY J. FREDERICK HALLER, M.D.,

*Member of the Committee on Legislation of the Rhode Island Medical Society.*

**MR. CHAIRMAN AND GENTLEMEN OF THE COMMITTEE:**—As one of the members of the Committee on Legislation of the Rhode Island Medical Society, and having given the subject of Medical Legislation some thought, study and attention, I desire to ask your indulgence for a few minutes to certain facts and arguments bearing directly and indirectly on the object of this bill.

In nothing is the progress of the age more marked than in the spread of learning. General knowledge is not only becoming more widely diffused among the people, but the natural, specific and higher sciences—many of which are collateral to that of medicine—have developed enormously. Progress in medicine and its collateral branches has been so great, it has been so amplified and specialized, that its mastery in its entirety is almost impossible, even for the ablest and best equipped. We must therefore admit, that no one is adequately prepared to successfully take up the study of such an elaborate and technical subject who does not already possess a fair, if not liberal, general education.

Fundamental training of the mind is necessary to higher studies. In no science is this more true than in the study of medicine. Physicians are the guardians of the health of the people,—health, the richest and grandest possession a man or woman has, be he or she rich or poor, learned or ignorant, the most prominent or the humblest of our citizens. Thomas Carlyle says: "Our health is to be constantly attended to, and regarded as the very highest of temporal things. No achievement in the world is equal to perfect health. What to it are nuggets and millions." No man, no matter how bright he may be by nature, be he the seventh son of a seventh son, or claim other supernatural and inherited gifts, can properly master or even understand modern medicine, unless he is well educated. Can any member of the legal profession present in this room point me out a man who would have the audacity to come before our courts to practise law, without a knowledge of law? And if he did, how do you suppose he would be treated by the learned judges? Has ever a historian attained any prominence who was not a scholar? Has ever a statesman risen above the level of his colleagues unless he was a man with a cultured mind? And so it has been and is, in every walk of life. Can a carpenter build a house without the necessary tools and knowledge? How can any one understand and advise in all the ailments to which the human flesh is heir without any intellectual and practical training? How can any one know disease, departure from normal, if he does not know what the normal is?

We lay a solid foundation first, if we are to erect a building; and why should not every man or woman who wishes to practice the healing art lay a solid foundation for their life-work by a thorough study of physics, chemistry, anatomy, physiology, *materia medica*, etc.?

A child must creep before he can walk. Educators are constantly at work to raise the professional standard, but they are unable to do so alone; the principal remedy lies with the various State Legislatures in creating independent and impartial boards to examine into the qualifications of aspirants to be entrusted with the health and lives of the people.

The constitutionality of enacting such laws by the States, was forever settled by the United States Supreme Court in the case of *Dent vs. the State of West Virginia*, in January, 1889.

The principal arguments against legislation of this kind in past years have been: (1) Class legislation; (2) Interference with individual rights; (3) Affording protection to doctors; (4) Creating a monopoly.

I may briefly answer that legislation of this nature belongs to the police powers of the State. If we consider this to be class legislation, then any and all bills to tax and license venders, traders, peddlers and travelling merchants come under the same head. Any law regulating insurance companies, banking institutions, and corporations of all kinds does the same. Our license-law for the regulation of the liquor traffic is then class legislation of the most pronounced kind; so with prohibitory amendments. Every time you incorporate a business firm, a society, a church, you legislate for classes. The Pharmacy Act and the Dental Law were then legislation for classes. This bill, which tends to regulate the practice of medicine in this State, is no more class legislation than any legislative enactment heretofore mentioned, but belongs clearly to the police powers of the State. Does this bill interfere with individual rights? Do you believe in knocking a man down, in afterwards kicking him and running away with his money, because he is sick and unable to defend himself? If this is individual rights, the police powers of the State ought to protect him from such individual wrongs.

In regard to protecting the doctors, and creating for us a monopoly this bill does nothing of the kind, for ignorant quacks produce much sickness and mischief; and as the appointing power is left to the governor's discretion, we may expect an impartial board, that will give fair consideration to any respectable interests. There is an inherent principle of justice and force in the regulation of the practice of medicine by the State; and States without any laws in this particular will surely have all the professional garbage, all the medical refuse from other bordering States with restrictive laws, dumped upon them, and the question of self-preservation will sooner or later compel the citizen and the legislator to protect themselves by the only remedy open to them—medical legislation.

Ex-Governor John M. Hamilton, of Illinois, said in one of his early reports to the Illinois State Legislature:

"The object of the Medical Practice Act was primarily a police-regulation. Incidentally it was educational. Primarily the purpose of the law was to rid the State of incompetent, ignorant and dangerous mountebanks and quacks, who were carrying on a fraudulent and nefarious business by all manner of deceit in a pretended practice of medicine among the people.

"It was to protect the lives, the health, the morals and the property of the people of the State from the shameless depredations of swindlers and adventurers who, by all manner of false representations and decep-

<sup>1</sup> Remarks before the Committee on Special Legislation of the State Senate of Rhode Island, at the public hearing, March 23, upon the "Medical Bill" introduced by Senator Brown from Providence.

tive promises, were taking advantage of the misfortunes of the people in sickness and ailments of all kinds to still further injure their health, endanger their lives and rob them of their money.

"Incidentally the law was designed to require a reasonable amount of education to fit one for the practice of medicine before he should be allowed to enter that profession, so directly and intimately connected with the lives, the health and the happiness of the people."

Sixteen years ago only one State had a medical license law. To-day nearly all the States have more or less stringent laws. North Carolina led the way in 1859. Kentucky came next in 1874. Nevada in 1875, California and Texas in 1876. Alabama and Illinois in 1877. Kansas and New York between 1877 and 1880. In 1881 nine States and one Territory enacted such laws, namely: Arizona, Arkansas, Colorado, Connecticut, Florida, Georgia, Nebraska, New Jersey, Pennsylvania and Wisconsin. About the only States now remaining without any kind of laws regulating the practice of medicine, are Rhode Island, Massachusetts, Maine, Connecticut, Kansas, and also the Territory of Utah. The general tendency of this legislation is towards securing a recognized standard of professional attainments, the best evidence of which is by an examination by a State Board of Medicine. There are to-day 450 physicians in the State of Rhode Island, and of these 248 belong to Providence alone. In this number are not included all those who practice the healing art, unknown outside of their immediate circles. This is more than is necessary to supply the legitimate demand for professional services, and a great number of these are not earning a comfortable livelihood from legitimate professional exertion.

Need we stop to dwell upon the demoralizing effect of the overproduction of practitioners, demoralizing equally to the individual, to the profession and to the public. Dr. John H. Rauch, Secretary of the Illinois State Board of Health, comes to the following conclusions:

"(1) That the best interests of the public welfare demand the highest attainable standard of educational qualifications, skill and ability as well as professional and personal honor, integrity and morality, among those engaged in the practice of medicine.

"(2) That in order to secure such a standard it is the duty of the State to exercise the inherent plenary power and authority which it possesses for the protection and promotion of the public welfare.

"(3) That uniform State laws, exacting of every one aspiring to practice medicine proof of personal fitness and professional competency, would prove the most potent agency in improving the standard of medical education and in enhancing the dignity and usefulness of the medical profession."

Allow me to briefly remind you of the dangers of having *no* or *no laws* protecting the health and lives of the people:

Our statute-books are crowded with provisions to protect the people from external violence, the murderer's bullet and knife. We have an army and a navy to protect us from assaults from foreign nations, and State militia to quell disturbances at home. The police on our streets serve the same purpose. Of late, with the advance of civilization, has come the establishment of health officers and boards of health to collect and record vital statistics; to look after the hygienic

condition of our homes, streets, alleys; to examine our food and drink, and detect adulteration; in short, to protect the people from a large class of dangers. The passage of the Pharmacy Act a few years ago was an admission on the part of the people that protection was needed in this direction. So with the Act that established our Board of Health.

Laws have been passed of late years, providing for the inspection and condemnation of diseased meat and cattle; also to discover adulteration of milk and food; although the laws have been but little enforced for the want of appropriation. And so on, step by step, have the representatives of the people awakened to the necessity of greater protection by law from the dangers to the lives of our citizens from causes within.

But, gentlemen, after you have legislated to examine impure food and milk; to prevent the spread of infectious diseases; to properly transport and bury the dead; to construct sewers and channels to remove impurities from our public places, streets and houses; to remove small-pox patients to isolated hospitals; for the proper care of the insane; for the proper rearing and care of the young people in our schools, — after you have enacted all these laws, you think that the community is safe; that you can fold your hands, and view with complacency the completeness of our statute-book.
